(2) Continuation. A contour separating the poles exists exactly when no pole $-a-n$ or $-b-n$ of the first two factors coincides with a pole $c + n'$ or $d + n'$ of the last two, $n, n' \in \mathbb{N}$, that is on the set U of $(a, b, c, d) \in \mathbb{C}^4$ with $a+c, a+d, b+c, b+d \notin -\mathbb{N}$. Near a point of U one fixed contour separates the poles, and by 1.3(iii) and 2.11 on one scale the four Gammas decay exponentially along it, locally uniformly in (a, b, c, d); so the left side is holomorphic on U, and by Cauchy's theorem it does not depend on the separating contour. The right side is holomorphic on U. The set U is connected, being the complement in $\mathbb{C}^4$ of countably many complex hyperplanes, and contains the open set of (1), so the identity holds on U. □

50.5 Chapter 5: the Trailmoment

Theorem 5.7 (The gauge of the coefficient function). *As stated: the last sentence at the unit configuration on any number of scales.*

Proof. The first two sentences are those of the reference (the reference, proof of 5.7). At the unit configuration $\mathsf{Z}_{\nu;I_{\mathcal{E}}}(\mathbf{c}) = \prod_e c_e^{-\nu_e} = \mathbf{c}^{-\nu}$ for every $\nu \in \mathbb{C}^{\mathcal{E}}$ (2.12), so by 5.1 $(\mathsf{T}_{\nu;I_{\mathcal{E}}}[\mathbf{c}]\,\phi)(Y') = \int_{Y'} \mathbf{c}^{-\nu}\, d\phi$, either side converging when the other does. □

Theorem 5.8 (Exchange and ladder of the Trailmoment). *As stated: (iii) at the unit configuration on any number of scales; (i) and (ii) are those of the reference.*

Proof. At $t = I_{\mathcal{E}}$ the column t_k is $\mathbf{e}_k$, $k \in \mathcal{E}$, so in (i) at the scale e only $k = e$ has $t_{k,e} \neq 0$, with $t_{e,e} = 1$ and the factor $\Gamma_1\begin{bmatrix}\nu_e+1\\1\end{bmatrix}\prod_{f\neq e}\Gamma_1\begin{bmatrix}\nu_f\\1\end{bmatrix} = 1$. Directly, for every ν, $\mathsf{Z}_{\nu;I_{\mathcal{E}}}(\mathbf{c}) = \mathbf{c}^{-\nu} = c_e\,\mathbf{c}^{-\nu-\mathbf{e}_e} = c_e\,\mathsf{Z}_{\nu+\mathbf{e}_e;I_{\mathcal{E}}}(\mathbf{c})$ (2.12); integrating against ϕ over Y' gives the first identity.

For the derivative, let $D \subseteq \mathbb{C}^{\mathcal{E}}$ be the set of indices where the Trailmoment converges, $\int_{Y'}\mathbf{c}^{-\operatorname{Re}\nu}\,d|\phi| < \infty$, and ν_0 an interior point of D. Take $\delta > 0$ such that $\nu_0 \pm \delta\mathbf{e}_e \in D$. For $\nu = \nu_0 + \zeta\mathbf{e}_e$ with $|\zeta| < \delta/2$, $|\mathbf{c}^{-\nu}\log c_e| = \mathbf{c}^{-\operatorname{Re}\nu_0}c_e^{-\operatorname{Re}\zeta}|\log c_e|$. For $\eta > 0$ and $y > 0$, $|\log y| \le \eta^{-1}(y^{\eta} + y^{-\eta})$; with $\eta = \delta/2$, and $y^{\theta} \le y^{\delta} + y^{-\delta}$ for $|\theta| \le \delta$,

$$\left|\mathbf{c}^{-\nu}\log c_e\right| \le \frac{4}{\delta}\Big(\mathbf{c}^{-(\operatorname{Re}\nu_0-\delta\mathbf{e}_e)} + \mathbf{c}^{-(\operatorname{Re}\nu_0+\delta\mathbf{e}_e)}\Big),$$

an integrable function independent of ζ. So $\zeta \mapsto \int_{Y'}\mathbf{c}^{-\nu_0-\zeta\mathbf{e}_e}d\phi$ may be differentiated under the integral sign, and $\partial_\zeta\mathbf{c}^{-\nu} = -(\log c_e)\,\mathbf{c}^{-\nu}$ gives the second identity. □

Proposition 5.14 (Laurent data of the Gamma at its poles). *As stated: the residue and the Laurent coefficients of a product of any number of Gammas with a common pole.*

Proof. The quotient form of $(-1)^j\varepsilon\Gamma(-j+\varepsilon)$, the expansion of its logarithm and $(\log\Gamma)'(j+1) = -(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((j,\infty))$ are those of the reference (the reference, proof of 5.14). On $|\varepsilon| < 1$ each $\phi_i(\varepsilon) := (-1)^{j_i}\varepsilon\,\Gamma(-j_i+\varepsilon) = \Gamma(1+\varepsilon)\Gamma(1-\varepsilon)/\Gamma(1+j_i-\varepsilon)$ is holomorphic and nonzero, and it is the exponential of the expansion at j_i. Put $b = -j+\varepsilon$; then $b + k_i = -j_i + \varepsilon$ and $\Gamma(b+k_i) = (-1)^{j_i}\varepsilon^{-1}\phi_i(\varepsilon)$, so

$$h(b)\prod_{i=1}^{p}\Gamma(b+k_i) = (-1)^{j_1+\cdots+j_p}\,\varepsilon^{-p}\,h(-j+\varepsilon)\prod_{i=1}^{p}\phi_i(\varepsilon).$$

The residue at $\varepsilon = 0$ is $(-1)^{\sum_i j_i}$ times the coefficient of ε^{p-1} in $h(-j+\varepsilon)\prod_i\phi_i(\varepsilon)$, and with $h(-j+\varepsilon) = \sum_l h^{(l)}(-j)\varepsilon^l/l!$ the Cauchy product gives the displayed sum. At $p = 2$ and $k_1 = k_2 = 0$, $\phi_1\phi_2 = \exp(2\log\phi_1) = (j!)^{-2}\big(1 - 2(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((j,\infty))\varepsilon + O(\varepsilon^2)\big)$, so the residue is $(j!)^{-2}\big(h'(-j) - 2(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((j,\infty))h(-j)\big)$, which is the formula of the reference. The Laurent coefficients of $\prod_i\Gamma(b+k_i)$ at $-j$ are $(-1)^{\sum_i j_i}$ times the Taylor coefficients of $\prod_i\phi_i = \prod_i(j_i!)^{-1}\exp\big(\sum_i(\log\phi_i + \log j_i!)\big)$; the series $\sum_i(\log\phi_i + \log j_i!)$ has no constant term and its coefficients are rational multiples of the Trailmoments $(\mathsf{T}_{k;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((j_i,\infty))$ and $(\mathsf{T}_{2k;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$, so the Taylor coefficients of its exponential are polynomials in these Trailmoments with rational coefficients. □

Remark. The residue formula was checked in exact arithmetic for $p = 2, 3, 4$ at several j and (k_i) (`sweep/s0107/resonance.py`).

Proposition 5.22 (The joint Laplace transform of Dirichlet inputs). *As stated, for finite sums of monomials with nonnegative real exponents.*

Proof. (1) The series. Every exponent $\mathbf{a}$ lies in $[0,\infty)^{\mathcal{E}}$, so $0 < u^{\mathbf{a}} \le 1$ on the source $\prod_Q\Delta_Q$ and $|P_i(u)| \le \|P_i\| := \sum_{\mathbf{a}}\big|[u^{\mathbf{a}}]P_i\big|$. Hence $\sum_{\mathbf{k}}\frac{|v|^{\mathbf{k}}}{\mathbf{k}!}\prod_i|P_i(U)|^{k_i} \le \exp\big(\sum_i|v_i|\,\|P_i\|\big)$, the exponential series of $\exp(-\sum_i v_iP_i(U))$ converges uniformly on the source for each $v \in \mathbb{C}^q$ and integrates term by term, and $\mathcal{F}(v) = \sum_{\mathbf{k}}\frac{(-v)^{\mathbf{k}}}{\mathbf{k}!}\mathbb{E}[\prod_i P_i(U)^{k_i}]$, a power series converging on $\mathbb{C}^q$, hence entire.

(2) The moments. Multiplying out, $\prod_i P_i^{k_i} = \sum_{\mathbf{a}}[u^{\mathbf{a}}]\big(\prod_i P_i^{k_i}\big)u^{\mathbf{a}}$, a finite sum with exponents in $[0,\infty)^{\mathcal{E}}$. The blocks of U are independent, so $\mathbb{E}[U^{\mathbf{a}}] = \prod_Q\mathbb{E}_{U_Q\sim\mathrm{Dir}_{\mathbf{m}|_Q}}[U_Q^{\mathbf{a}|_Q}]$, and by 3.11 at the

exponents $\mathbf{a}|_Q$, whose real parts satisfy $m_e + a_e > 0$, together with 1.3(i),(ii),

$$\mathbb{E}_{U_Q \sim \mathrm{Dir}_{\mathbf{m}|_Q}}\big[U_Q^{\mathbf{a}|_Q}\big] = \frac{\Gamma_{|Q|}\begin{bmatrix}\mathbf{m}|_Q + \mathbf{a}|_Q \\ m_Q + a_Q\end{bmatrix}}{\Gamma_{|Q|}\begin{bmatrix}\mathbf{m}|_Q \\ m_Q\end{bmatrix}} = \prod_{e\in Q} \Gamma_1\begin{bmatrix}m_e + a_e \\ m_e\end{bmatrix}\ \Gamma_1\begin{bmatrix}m_Q \\ m_Q + a_Q\end{bmatrix}.$$

Summing gives $M(\mathbf{k})$; for integer exponents 3.11 gives the rising factorials.

(3) The read. Where every P_i is positive on the interior of the source, which carries the law, 2.12 and 2.1 give $\mathsf{Z}_{\nu;t}(\mathbf{P}(U)) = \frac{1}{\prod_j \Gamma(\nu_j)} \int_{(0,\infty)^d} x^{\nu-\mathbf{1}} \exp\big(-\sum_i P_i(U) x^{t_i}\big) dx$ where this converges. By Tonelli on the moduli and Fubini, wherever the double integral converges, the expectation of the left side is the integral of $\mathbb{E}[\exp(-\sum_i P_i(U)x^{t_i})] = \mathcal{F}(x^{t_1}, \dots, x^{t_q})$ against $x^{\nu-\mathbf{1}}dx/\prod_j \Gamma(\nu_j)$. The left side is the Trailmoment $(\mathsf{T}_{\nu;t}[(P_i)_i] \otimes_Q \mathrm{Dir}_{\mathbf{m}|_Q})(\prod_Q \Delta_Q)$ by 5.1.

(4) Uniqueness. With real coefficients the vector $(P_i(U))_i$ takes its values in the compact box $\prod_i [-\|P_i\|, \|P_i\|]$, and its moments $\mathbb{E}[\prod_i P_i(U)^{k_i}] = M(\mathbf{k})$ are the integrals of the monomials against its law. Polynomials are dense in the continuous functions on the box, so a law on the box is determined by these integrals; and the read $\mathbb{E}[\mathsf{Z}_{\nu;t}(\mathbf{P}(U))]$ depends on the law of $\mathbf{P}(U)$ alone. □

Theorem 5.26 (The Shruffle on a line). *As stated: (i) and (iii) for any number of strings and of trails; (ii) is that of the reference.*

Proof. (i) Let $w^{(i)}$ have length n_i, $n = \sum_i n_i$, and $S_i = \{x_1^{(i)} > \cdots > x_{n_i}^{(i)} > 0\}$. By Tonelli the function $\prod_i \prod_j w_j^{(i)}(x_j^{(i)})$ is integrable on $S_1 \times \cdots \times S_r$, with integral $\prod_i \mathrm{chain}(w^{(i)})$ by Fubini. The points with two equal coordinates form a null set. At every other point the n coordinates are distinct, and their decreasing order is a total order of the n positions (i,j) that restricts to the order of each string: an interleaving ς, the string of the n functions in that order. The points of one interleaving are carried by a permutation of the coordinates, which keeps Lebesgue measure, onto $\{y_1 > \cdots > y_n > 0\}$, the integrand becoming $\prod_m \varsigma_m(y_m)$; so their integral is $\mathrm{chain}(\varsigma)$. The interleavings are the ways of distributing the n places among the strings, $n!/(n_1! \cdots n_r!)$ of them.

(iii) Let r trails be as in (ii), with strings $\sigma^{(1)}, \dots, \sigma^{(r)}$ and cuts $N_1, \dots, N_r$. By (ii) the trail i is $\mathrm{chain}(\sigma^{(i)})$, and by (i) the product is $\sum_\varsigma \mathrm{chain}(\varsigma)$ over the interleavings. An interleaving begins with the first function of one of the strings, a Laplace transform $e^{-N_i \cdot} L_1^{(i)}$, which is $\int e^{-(s+N_i)\cdot} \psi(ds)$ for the first increment ψ of trail i: the Laplace transform of its image under $s \mapsto s + N_i$, carried by $(0,\infty)$ by the hypothesis of (ii). The other Laplace transforms of ς are those of nonnegative increments or of such images. Reading ς as in (ii), each Laplace transform followed by its run of constant functions 1 gives an increment with the index one more than the length of the run; the trail at the cut 0 with these increments has no constant columns and positive integer indices, and by (ii) it is $\mathrm{chain}(\varsigma)$. □

Theorem 5.27 (Trails at frequencies are iterated integrals). *As stated.*

Proof. For a word $\ell = (\ell_1, \dots, \ell_w)$ with $\ell_1 \neq 0$ and letters in $\{0\} \cup \{|z| = 1\}$ put $F_\varnothing = 1$ and $F_\ell(z) = \int_0^z F_{\ell'}(t)\, dt/(t - \ell_w)$ on the disc $|z| < 1$, ℓ' the word without its last letter, along the segment. By induction F_ℓ is holomorphic on the disc with $F_\ell(0) = 0$ for $w \geq 1$: for $\ell_w \neq 0$ the factor $1/(t - \ell_w)$ is holomorphic there, and for $\ell_w = 0$, $F_{\ell'}(t)/t$ is, as $F_{\ell'}(0) = 0$, the word ℓ' being nonempty since $\ell_1 \neq 0$. Unwinding the recursion, $F_\ell(z)$ is the iterated integral over $0 < t_1 < \cdots < t_w < z$ along the segment.

For $|z| < 1$ let $S(z) = \sum_{0<n_1<\cdots<n_d} \prod_i \zeta_i^{n_i} n_i^{-\nu_i} z^{n_d}$, absolutely convergent, the trail with z^{y_d} in its density, $S(0) = 0$. If $\nu_d \geq 2$, $zS'(z)$ is the same series with $\nu_d - 1$ in place of ν_d, whose word

is ℓ without its last letter 0, and $S(z) = \int_0^z S_{\nu_d-1}(t)\,dt/t$. If $\nu_d = 1$, summing the geometric series over $n_d > n_{d-1}$,

$$S'(z) = \sum_{0<n_1<\cdots<n_{d-1}} \prod_{i<d} \zeta_i^{n_i} n_i^{-\nu_i}\ \frac{\zeta_d\,(\zeta_d z)^{n_{d-1}}}{1-\zeta_d z} = \frac{\zeta_d}{1-\zeta_d z}\,S^\flat(z),$$

where $S^\flat$ is the series of depth $d-1$ with the last frequency $a_{d-1}+a_d$, so $\zeta_{d-1}\zeta_d$, and $S^\flat = 1$ when $d = 1$. Its c_i are those of S for $i < d$, its word is ℓ without the last letter $c_d^{-1} = \zeta_d^{-1}$, and $\zeta_d/(1-\zeta_d z) = -1/(z-\zeta_d^{-1})$, so $S(z) = -\int_0^z S^\flat(t)\,dt/(t-\zeta_d^{-1})$. By induction on w, $S = (-1)^d F_\ell$ on the disc, which is the last sentence.

Write $S(z) = \sum_n b_n z^n$ with $b_n = A(n)\zeta_d^n n^{-\nu_d}$, $A(n) = \sum_{0<n_1<\cdots<n_{d-1}<n} \prod_{i<d} \zeta_i^{n_i} n_i^{-\nu_i}$, $A = 1$ when $d = 1$; then $|A(n)| \le (1+\log n)^{d-1}$, and the head over $y_d \le N$ is $\sum_{n\le N} b_n$. For $\nu_d \ge 2$ the series $\sum b_n$ converges absolutely, so the heads converge to the trail. For $\nu_d = 1$ the partial sums of ζ_d^n are bounded by $2/|1-\zeta_d|$, and $A(n)/n \to 0$ with $\sum_n |A(n+1)/(n+1) - A(n)/n| \le \sum_n C(1+\log n)^{d-1} n^{-2} < \infty$, since $A(n+1) - A(n)$ is the sum of the terms with $n_{d-1} = n$; summation by parts makes $\sum b_n$ converge. By Abel's theorem on power series, $S(z) \to \sum_n b_n$ as $z \to 1$ along $[0,1)$.

On the other side, the integrand $\prod_j 1/|t_j - \ell_j|$ on the simplex of $[0,1]$ is at most $C \prod_{\ell_j=0} t_j^{-1} \prod_{\ell_j=1} (1-t_j)^{-1}$, the other letters lying off $[0,1]$. Split the simplex by the number of the t_j below $\frac12$; on the part below, with $\ell_1 \ne 0$, the iterated integrals $G_j(t)$ of the first j factors over $0 < t_1 < \cdots < t_j < t$ satisfy $G_1(t) \le Ct$ and $G_j(t) \le \int_0^t G_{j-1}(s)\,C(1+1/s)\,ds \le C_j t$; on the part above the same holds after $t \mapsto 1-t$, as $\ell_w \ne 1$ ($\ell_w = 0$ when $\nu_d \ge 2$, $\ell_w = \zeta_d^{-1} \ne 1$ when $\nu_d = 1$). So the integral over $0 < t_1 < \cdots < t_w < 1$ converges absolutely, and by dominated convergence $F_\ell(z)$ tends to it as $z \to 1$ along $[0,1)$. Hence the limit of the heads is $(-1)^d$ times that integral. □

Theorem 5.31 (Two convolutions). *As stated: (ii) and (iii) at the unit configuration on any number of scales; (i) and the displays of (ii) for inputs carried by $(0,\infty)$ are those of the reference.*

Proof. (ii) By 2.12, $\mathsf{Z}_{\nu;I_\mathcal{E}}(\mathbf{c}\,\mathbf{c}') = \prod_e (c_e c'_e)^{-\nu_e} = \mathsf{Z}_{\nu;I_\mathcal{E}}(\mathbf{c})\,\mathsf{Z}_{\nu;I_\mathcal{E}}(\mathbf{c}')$ at every point of $Y_1 \times Y_2$. The two Trailmoments on the right converge, so by Tonelli the kernel is integrable for $|\phi| \otimes |\psi|$ on $Y_1' \times Y_2'$, and Fubini gives the product (5.1).

(iii) *The kernel on sums.* First, g has no zero: if $g(s_0) = 0$, then $g(s_0/2)^2 = g(s_0) = 0$, so $g(s_0/2^n) = 0$ for every n; every $s \in (0,\infty)^\mathcal{E}$ has $s - s_0/2^n \in (0,\infty)^\mathcal{E}$ for n large, and $g(s) = g(s_0/2^n)\,g(s - s_0/2^n) = 0$, against the hypothesis. Fix $e \in \mathcal{E}$. For $s, s'' \in (0,\infty)^\mathcal{E}$ and $\tau > 0$, $g(s+\tau\mathbf{e}_e)\,g(s'') = g(s+s''+\tau\mathbf{e}_e) = g(s''+\tau\mathbf{e}_e)\,g(s)$, so $\varphi_e(\tau) = g(s+\tau\mathbf{e}_e)/g(s)$ does not depend on s. It is continuous on $(0,\infty)$, has no zero, and $\varphi_e(\tau+\tau') = \varphi_e(\tau)\,\varphi_e(\tau')$, by the independence of the base point applied at s and at $s+\tau\mathbf{e}_e$. By the converse on one scale, the case $|\mathcal{E}| = 1$ (the reference, proof of 5.31), $\varphi_e(\tau) = e^{-u_e\tau}$ for one $u_e \in \mathbb{C}$, and then $g(s+\tau\mathbf{e}_e) = e^{-u_e\tau} g(s)$ also for $\tau < 0$ with $s + \tau\mathbf{e}_e \in (0,\infty)^\mathcal{E}$, applying it at the base point $s+\tau\mathbf{e}_e$. Moving one coordinate at a time from a fixed point s_1, $g(s) = C\,e^{-\langle u,s\rangle}$ on $(0,\infty)^\mathcal{E}$ with $C = g(s_1)e^{\langle u,s_1\rangle} \ne 0$, and $g(s+s') = g(s)\,g(s')$ gives $C = C^2$, so $C = 1$.

The kernel on products. If $h(x) \ne 0$, then $h(x) = h(x)\,h(\mathbf{1})$ gives $h(\mathbf{1}) = 1$, and $h(x)\,h(x^{-1}) = h(\mathbf{1}) = 1$ shows that h has no zero. The function $s \mapsto h(e^s)$ on $(0,\infty)^\mathcal{E}$ is continuous, not identically zero and satisfies the hypothesis on sums, so $h(e^s) = e^{-\langle u,s\rangle}$, that is $h(x) = x^{-u}$ for every x with all coordinates above 1. Any $x \in (0,\infty)^\mathcal{E}$ is x'/x'' with $x''_e > \max(1, 1/x_e)$ and $x' = x\,x''$, both with all coordinates above 1, and $h(x) = h(x')/h(x'') = x^{-u}$. So $h = \mathsf{Z}_{u;I_\mathcal{E}}$. □

50.6 Chapter 6: rational words and live inputs

Theorem 6.4 (Pole columns are a rational difference quotient). *As stated: coefficients in any subfield of $\mathbb{C}$, and no decay condition.*

Proof. (1) The decomposition. For $k \ge 0$ and $s \ge 1$, telescoping gives $\Delta \sum_{j=0}^{k-1} (t+j)^{-s} = \sum_{j=0}^{k-1} \big((t+j+1)^{-s} - (t+j)^{-s}\big) = (t+k)^{-s} - t^{-s}$. So $\Delta H(t) = \sum_{k,s} c_{k,s}\big((t+k)^{-s} - t^{-s}\big) = R(t) - \sum_s C_s t^{-s}$, and H has its coefficients in $\mathbb{K}$.

(2) The decay. As $t \to \infty$, $(t+k)^{-s} = t^{-s}(1+k/t)^{-s} = t^{-s} + O(t^{-s-1})$, so $R(t) = C_1 t^{-1} + O(t^{-2})$, which is $O(t^{-2})$ exactly when $C_1 = 0$.

(3) The converse. A proper rational function H with poles on the nonpositive integer lattice has one partial-fraction presentation $H(t) = \sum_{k,s} d_{k,s}(t+k)^{-s}$, finitely many terms with $k \in \mathbb{N}$, $s \ge 1$. Then $\Delta H(t) = \sum_{k,s} d_{k,s}\big((t+k+1)^{-s} - (t+k)^{-s}\big)$, whose coefficient of $(t+k)^{-s}$ is $d_{k-1,s} - d_{k,s}$ (with $d_{-1,s} = 0$), and the column sum over k telescopes to 0. The column sums $R \mapsto (C_s)_s$ are linear on rational words, presentations being unique, and vanish on such differences. A combination $\sum_s a_s t^{-s}$ has the column sums $(a_s)_s$, so it is a difference only if it is 0: the functions $t^{-1}, \dots, t^{-w}$ are independent modulo differences, and by (1) they span the rational words of maximum order w modulo differences. A difference is a rational word with column sums zero, hence $O(t^{-2})$ by (2); and a word that is $O(t^{-2})$ has $C_1 = 0$, so it is congruent to $\sum_{s \ge 2} C_s t^{-s}$: modulo differences these words have the basis $t^{-2}, \dots, t^{-w}$.

(4) Cosets. Translation by one keeps each coset $b + \mathbb{Z}$, so the steps above apply coset by coset, with $(t+b)^{-s}$ in the place of t^{-s}. □

Theorem 6.5 (Summation by parts with a live input). *As stated: (iv) without the condition $C_1 = 0$; (i) to (iii) are those of the reference.*

Proof. (iv) For an integer $M \ge 1$ the head is $(\mathsf{T}_{0;(1)}[x]\, R\, \mathbb{I}_{\mathbb{Z}})((N, N+M]) = \sum_{N < m \le N+M} R(m)$, the kernel at index 0 being 1. By 6.4, $R(m) = \sum_s C_s m^{-s} + H(m+1) - H(m)$, so

$$(\mathsf{T}_{0;(1)}[x]\, R\, \mathbb{I}_{\mathbb{Z}})((N, N+M]) = \sum_{s=1}^{w} C_s\, (\mathsf{T}_{s;(1)}[x]\, \mathbb{I}_{\mathbb{Z}})((N, N+M]) + H(N+M+1) - H(N+1).$$

As $M \to \infty$: $H(N+M+1) \to 0$, H being proper; for $s \ge 2$, $(\mathsf{T}_{s;(1)}[x]\, \mathbb{I}_{\mathbb{Z}})((N, N+M]) \to (\mathsf{T}_{s;(1)}[x]\, \mathbb{I}_{\mathbb{Z}})((N, \infty))$; and $(\mathsf{T}_{1;(1)}[x]\, \mathbb{I}_{\mathbb{Z}})((N, N+M]) - \log M \to (\mathsf{T}_{1;(1)}[x]\, \mathbb{I}_{\mathbb{Z}})((N, \infty))$, the regularized value of 5.2. This gives the first display. When $C_1 = 0$, $R(m) = O(m^{-2})$ by 6.4, the series $\sum_{m>N} R(m)$ converges absolutely, and the left side is $(\mathsf{T}_{0;(1)}[x]\, R\, \mathbb{I}_{\mathbb{Z}})((N, \infty))$, the term $s = 1$ being absent. For a density f, when the terms converge, $\sum_{m>N} R(m) f(m) = \sum_{s=1}^{w} C_s \sum_{m>N} m^{-s} f(m) + \sum_{m>N} \Delta H(m) f(m)$, and (ii) gives the last two terms of the second display when the upper boundary vanishes. □

Theorem 6.8 (A Breta input with a recurrence of finite order). *As stated: complex a, b with positive real parts, real $q_i < 1$ of either sign, and complex s_i.*

Proof. (1) The letters. For real $q_i < 1$ and $x \in [0,1]$, $1 - q_i x$ lies between 1 and $1 - q_i$, so in $[\min(1, 1-q_i), \max(1, 1-q_i)] \subset (0, \infty)$. So $\varrho(x) = \prod_i (1 - q_i x)^{-s_i}$ is infinitely differentiable on $[0,1]$, and $|\varrho| = \prod_i (1 - q_i x)^{-\operatorname{Re} s_i}$ lies between two positive constants.

(2) The size. For $m \ge 1$, by $x \le e^{-(1-x)}$ on $[0,1]$ and $y = 1 - x$,

$$|f(m)| \le \max |\varrho| \int_0^1 x^{m + \operatorname{Re} a - 1} (1-x)^{\operatorname{Re} b - 1} dx$$

$$\le \max|\varrho| \int_0^\infty e^{-(m+\operatorname{Re} a-1)y} y^{\operatorname{Re} b-1} dy = \max|\varrho|\,\Gamma(\operatorname{Re} b)\,(m+\operatorname{Re} a-1)^{-\operatorname{Re} b},$$

so $f(m) = O(m^{-\operatorname{Re} b})$.

(3) The recurrence. Differentiating the logarithm, $\frac{d}{dx}\big[x^{m+a}(1-x)^b \prod_i (1-q_i x)^{1-s_i}\big]$ is $x^{m+a-1}(1-x)^{b-1}\varrho(x)$ times

$$(m+a)(1-x)Q(x) - bxQ(x) + x(1-x)\sum_i (s_i-1)q_i Q_i(x) = B_m(x).$$

The bracket tends to 0 at both ends, since $\operatorname{Re}(m+a) > 0$ and $\operatorname{Re} b > 0$, and $x^{m+a-1}(1-x)^{b-1}\varrho B_m$ is integrable; so integrating over $[0,1]$ gives $\sum_\ell B_\ell(m) f(m+\ell) = 0$.

(4) The extreme coefficients. $B_0(m) = B_m(0) = (m+a)Q(0) = m+a$. Every $q_i \neq 0$, so Q has degree r and leading coefficient $(-1)^r \prod_i q_i$, and Q_i has degree $r-1$ and leading coefficient $(-1)^{r-1}\prod_{i'\neq i} q_{i'}$. The coefficient of x^{r+1} in B_m is therefore

$$(-1)^{r+1}\prod_i q_i\Big((m+a)+b+\sum_i (1-s_i)\Big) = (-1)^{r+1}\Big(\prod_i q_i\Big)\Big(m+a+b+r-\sum_i s_i\Big).$$

$B_0(m) \neq 0$ since $\operatorname{Re} a > 0$, and $B_{r+1}(m) \neq 0$ for every integer $m \ge 0$ exactly when $a+b+r-\sum_i s_i \notin -\mathbb{N}$. Then the recurrence solved for $f(m+r+1)$, and for $f(m)$, expresses every shift through $(f(m),\dots,f(m+r))$ with coefficients rational in m.

(5) The Breta. Let $\operatorname{Re} s_i > 0$. On the bunch $\{1,2\}$ with the scale ρ and the shape $u = (x, 1-x)$, $\omega_{\{1,2\}}$ being dx in the coordinate $x = u_1$, the kernel terms ρu_1 and ρu_2 with unit coefficients sum to ρ, and the letter $P_i = \rho\big((1-q_i)u_1 + u_2\big) = \rho(1-q_i x)$ has the positive pattern coefficients $1-q_i$ and 1. At the shape index $(m+a, b)$ and the scale index $1+|\mathbf{s}|$ the left side of 3.6 is

$$\int_0^1 x^{m+a-1}(1-x)^{b-1}\int_0^\infty \rho^{|\mathbf{s}|}e^{-\rho}\rho^{-|\mathbf{s}|}\prod_i (1-q_i x)^{-s_i}\,d\rho\,dx = f(m),$$

the inner integral being $\Gamma(1) = 1$; 3.6 identifies it with $\Gamma(1+|\mathbf{s}|)$ times the Breta. □

Theorem 6.9 (A fixed set of input-dependent evaluations). *As stated, for the data of 6.8.*

Proof. The steps of the reference, proof of 6.9, hold for these data; they are as follows. Write $F_{p,k}(N) = (\mathsf{T}_{p;(1)}[x+k]\, f\, \mathbb{I}_{\mathbb{Z}})((N,\infty)) = \sum_{m>N} f(m)(m+k)^{-p}$, and, for $0 \le x < 1$, $S_p(x) = \sum_{m>N} x^m (m+k)^{-p}$, with an integer cut $N \ge 0$ and $k \ge 0$; $S_0(x) = x^{N+1}/(1-x)$.

(1) The identity behind (ii). As in the proof of 6.8, $(xC\eta)' = B\eta$, with $xC\eta = x^a(1-x)^b\prod_i(1-q_i x)^{1-s_i}$. Since $xS_p'(x) = \sum_{m>N} m\, x^m (m+k)^{-p} = S_{p-1}(x) - kS_p(x)$,

$$\frac{d}{dx}\big[xC\eta\, S_p\big] = \eta\big[(B-kC)S_p + C\, S_{p-1}\big] \qquad (p \ge 1).$$

At $x = 0$ the bracket is $O(|x^{a+N+1}|) \to 0$, since $\operatorname{Re} a > 0$. At $x = 1$ it is bounded by a constant times $|(1-x)^b|$ for $p \ge 2$, where $S_p(1)$ is finite, and times $|(1-x)^b|\,|\log(1-x)|$ for $p = 1$, where $S_1(x) = O(|\log(1-x)|)$; it tends to 0 since $\operatorname{Re} b > 0$. The functions $|\eta|\, S_p$ and $|\eta|\,|\log(1-x)|$ are integrable on $[0,1)$, so integrating over $[0,1)$ and summing term by term (Tonelli on the moduli) gives, for $p \ge 2$,

$$\sum_{m>N}(m+k)^{-p}\int_0^1 x^m (B-kC)\eta\,dx + \sum_{m>N}(m+k)^{1-p}\int_0^1 x^m C\eta\,dx = 0.$$

With $\int_0^1 x^{m+\ell}\eta\,dx = f(m+\ell)$ and, for $k \ge r+1 \ge \ell$, $\sum_{m>N} f(m+\ell)(m+k)^{-p} = F_{p,k-\ell}(N) - \sum_{v=1}^{\ell} f(N+v)(N+v+k-\ell)^{-p}$, this is (ii) for $p \ge 2$. At $p=1$ the term with S_0 is $\int_0^1 \eta\, C\, S_0\, dx = \int_0^1 \eta\, x^{N+1} Q\, dx = \sum_{\ell=0}^{r} Q_\ell f(N+1+\ell)$, by $C\,S_0 = x^{N+1}Q$, which gives (ii) at $p=1$.

(2) The reduction (i). In (ii) the coefficient of $F_{p,k}(N)$, the term $\ell = 0$, is $B_0 - kC_0 = a - k$, since $B(0) = aQ(0) = a$ and $C(0) = 1$. For $k \ge r+1$ with $k \ne a$, (ii) expresses $F_{p,k}(N)$ through the $F_{p,k-\ell}(N)$, $1 \le \ell \le r+1$, the $F_{p-1,k-\ell}(N)$ (none at $p=1$), and the values $f(N+v)$, $1 \le v \le r+1$. Taking the indices p in increasing order and, for each, the shifts k in increasing order, every $F_{p,k}(N)$ with $p \le A$ reduces to the $F_{p',k'}(N)$ with $p' \le p$ and $k' \le r$, the $F_{p',a}(N)$ when a is an integer at least $r+1$, and $f(N+1), \dots, f(N+r+1)$.

(3) The cuts (iii) are 5.3 for the counting input.

(4) Denominators (iv). For rational data, let c_* clear the coefficients of B, C and Q, so that $c_*(a-k)$, $c_*(B_\ell - kC_\ell)$, c_*C_ℓ and c_*Q_ℓ are integers for integer k. By induction along the order of (2), the coefficients of $F_{p,k}(N)$, $k \ge r+1$, in the reduced form are cleared by $D_{p,k} = d_{N+k}^{p} \prod_{r+1 \le k' \le k,\ k' \ne a} |c_*(a-k')|^p$. Multiply (ii) by c_* and divide by $c_*(a-k)$: the terms $F_{p,k-\ell}(N)$ and $F_{p-1,k-\ell}(N)$ carry integer factors, and their reduced forms are cleared by $D_{p,k-\ell}$ and $D_{p-1,k-\ell}$, which divide $D_{p,k}/|c_*(a-k)|$; the terms in $f(N+v)$ carry the denominators $(N+v+k-\ell)^p$ and $(N+v+k-\ell)^{p-1}$, which divide d_{N+k}^{p}, since $1 \le N+v+k-\ell \le N+k$. So $D_{p,k}$ clears $F_{p,k}(N)$, and $d_{N+J}^{A} \prod_{r+1 \le k \le J,\ k \ne a} |c_*(a-k)|^A$, a multiple of every $D_{p,k}$ with $p \le A$ and $k \le J$, clears all shifts through J and indices through A. □

Theorem 6.10 (The row of a rational function against an input with a recurrence). *As stated.*

Proof. All the sums converge absolutely: $m + h \ge N + 1 + h_* > 0$ for $m > N$ and $h \ge h_*$, and $\sum_{m>N} |f(m)|(1+|m|)^d < \infty$. (i) is linearity, $P(m) = \sum_r ([m^r]P) m^r$.

(ii) Expand p_i about $-h$: $p_i(m) = \sum_e \pi_{i,e}(h)(m+h)^e$ with $\pi_{i,e}(h) = p_i^{(e)}(-h)/e!$. Multiply the recurrence at m by $(m+h)^{-s}$, sum over $m > N$ and put $m' = m + i$:

$$\sum_{i=0}^{\tau} \sum_{e} \pi_{i,e}(h) \sum_{m' > N+i} f(m')\,(m'+h-i)^{e-s} = 0.$$

Moving the cut of each inner sum to N (5.3) and writing, for $e \ge s$, $(m'+h-i)^{e-s} = \sum_{r \le e-s} \binom{e-s}{r} (h-i)^{e-s-r} m'^r$,

$$\begin{aligned} p_0(-h)\,T_s(h) = &\sum_{i=1}^{\tau} \sum_{v=1}^{i} \sum_{e} \pi_{i,e}(h)\, f(N+v)\,(N+v+h-i)^{e-s} \\ &- \sum_{(i,e) \ne (0,0),\ e<s} \pi_{i,e}(h)\, T_{s-e}(h-i) - \sum_{e \ge s} \sum_{i} \pi_{i,e}(h) \sum_{r \le e-s} \binom{e-s}{r} (h-i)^{e-s-r} M_r, \end{aligned}$$

with $\pi_{0,0}(h) = p_0(-h)$. At $h = h_* + j$, $\tau \le j \le J$, divide by $p_0(-h) \ne 0$: the right side holds $T_{s'}$ with $s' < s$ at the same shift, or with $s' \le s$ at the smaller shifts $h - i \ge h_*$, moments M_r with $r \le d - s \le d-1$, and the values $f(N+v)$, $v \le \tau$. Induction on j, and for fixed j on s, gives (ii); all coefficients are rational.

(iii) Put $Q(s,j) = d_{u(N+h_*+j)}^{s} \prod_{j'=\tau}^{j} |u^d p_0(-h_* - j')|^s$; we show by the same induction that $Q(s,j)$ clears the coefficients of $T_s(h_* + j)$, and $Q(s,j)$ divides the integer of (iii). Since $h \in \frac{1}{u}\mathbb{Z}$ and $p_i \in \mathbb{Z}[m]$, $\pi_{i,e}(h)$ has a denominator dividing $u^{\deg p_i - e}$, and $u^d p_0(-h)$ is an integer. Write the relation as $T_s(h) = \big(u^d p_0(-h)\big)^{-1} u^d\,[\cdots]$ and take its terms in turn.

- $T_{s-e}(h-i)$ with $i \geq 1$ or $e \geq 1$, $s-e \geq 1$: the factor $u^d \pi_{i,e}(h)$ is an integer, and the coefficients of $T_{s-e}(h-i)$ are 1 if it is a coordinate and are cleared by $Q(s-e, j-i)$ otherwise, by induction; $|u^d p_0(-h)|\, Q(s-e, j-i)$ divides $Q(s,j)$, as $s-e \leq s$, $j-i \leq j$, and when $i=0$, $e \geq 1$ leaves the factor $|u^d p_0(-h)|^e$ free in $Q(s,j)/Q(s-e,j)$.
- The moments: $u^d \pi_{i,e}(h)(h-i)^{e-s-r}$ has a denominator dividing $u^{-d+\deg p_i - e + e - s - r}$, an integer power of u with exponent at most 0, so it is an integer.
- The values $f(N+v)$: for $e < s$, $(N+v+h-i)^{e-s} = u^{s-e}\big(u(N+v+h-i)\big)^{e-s}$, where $u(N+v+h-i)$ is an integer with $1 \leq u(N+v+h-i) \leq u(N+h)$, positive since $h-i \geq h_*$ and $N+1+h_* > 0$; so its power $s-e \leq s$ divides $d^s_{u(N+h_*+j)}$, and $u^d \pi_{i,e}(h) u^{s-e}$ is an integer. For $e \geq s$ the term $u^d \pi_{i,e}(h)(N+v+h-i)^{e-s}$ has a denominator dividing $u^{\deg p_i - e + (e-s) - d}$, a power of u with exponent at most 0, so it is an integer.

Every coefficient of $T_s(h_*+j)$ is a sum of such products, so $Q(s,j)$ clears it; and for $s \leq w$, $j \leq J$, $Q(s,j)$ divides $d^w_{u(N+h_*+J)} \prod_{j'=\tau}^{J} |u^d p_0(-h_*-j')|^w$, as $d_n \mid d_{n'}$ for $n \leq n'$. Poles in several cosets are reduced coset by coset, each with its own u and h_*. □

50.7 Chapter 7: tables

Proposition 7.6 (Duality of minors). *As stated.*

Proof. Every basis has r marks, so $|T \cap X|$ is largest exactly when $|T \cap X'|$ is least, that is exactly when the cobasis $\mathcal{E} \setminus T$ has $|(\mathcal{E} \setminus T) \cap X'| = |X'| - |T \cap X'|$ largest: T is at the top of X exactly when $\mathcal{E} \setminus T$ is at the top of X' in $\mathcal{B}^*$ (7.5). By 7.5 the bases of $\mathcal{B}^*/X'$ are the sets $(\mathcal{E} \setminus T) \setminus X' = X \setminus (T \cap X)$ for these T, the complements in X of the bases $T \cap X$ of $\mathcal{B}|X$, and the bases of $\mathcal{B}^*|X'$ are the sets $(\mathcal{E} \setminus T) \cap X' = X' \setminus (T \setminus X)$, the complements in X' of the bases $T \setminus X$ of $\mathcal{B}/X$. The weight of the cobasis $\mathcal{E} \setminus T$ is $\theta_T = \theta'_{T \cap X} \theta''_{T \setminus X}$, the factor $\theta''_{T \setminus X}$ belonging to its part $X' \setminus (T \setminus X)$ and the factor $\theta'_{T \cap X}$ to its part $X \setminus (T \cap X)$; these are the weights of the dual tables of 7.1. The letters follow from 7.2. □

Theorem 7.15 (One function, two Foreman polynomials). *As stated: (iii) along every direction constant on the molecules of the table, with the converse; (i) and (ii) are those of the reference.*

Proof. The directions. By 7.9 for the family whose one table is this table, the table is the direct sum of its restrictions to its molecules M: every basis T is the union of one basis of each restriction $\mathcal{B}|M$, and a basis of $\mathcal{B}|M$ has $r(M)$ marks (7.5). So $|T \cap M| = r(M)$, and for v constant on each M, with value v_M,

$$\langle v, \chi_T \rangle = \sum_M v_M \big(|T \cap M| - |M \setminus T| \big) = \sum_M v_M \big(2r(M) - |M| \big)$$

for every basis. By 7.14, $\Lambda(z+v) = \sum_T \theta_T e^{\langle z, \chi_T \rangle} e^{\langle v, \chi_T \rangle} = \exp\big(\sum_M v_M (2r(M) - |M|) \big) \Lambda(z)$. At $v = \lambda \mathbf{1}$ the exponent is $\lambda(2r-n)$, the $r(M)$ adding up to r, since a basis meets each molecule in $r(M)$ marks, and the $|M|$ to n.

The converse. Let $v \in \mathbb{R}^{\mathcal{E}}$ and real $\lambda \neq 0$ be such that $\Lambda(z + \lambda v) = c\, \Lambda(z)$ for every $z \in \mathbb{R}^{\mathcal{E}}$, with c independent of z. Then $\sum_T \theta_T \big(e^{\lambda \langle v, \chi_T \rangle} - c \big) e^{\langle z, \chi_T \rangle} = 0$ for every z. Distinct bases have distinct signed indicators, and exponentials $e^{\langle z, \chi \rangle}$ with finitely many distinct vectors χ are linearly independent functions of z: on a line $z = \sigma y$ with the $\langle y, \chi \rangle$ distinct, as $\sigma \to \infty$ the term

with the largest $\langle y, \chi \rangle$ dominates, so its coefficient vanishes, and the others follow in turn. So $\theta_T(e^{\lambda\langle v,\chi_T\rangle} - c) = 0$, and since $\theta_T > 0$, $e^{\lambda\langle v,\chi_T\rangle} = c$ for every basis. Hence $\langle v, \chi_T\rangle = 2\langle v, \mathbf{1}_T\rangle - \langle v, \mathbf{1}\rangle$ is constant over the bases, and so is $\langle v, \mathbf{1}_T\rangle$. By 7.8, $v_a = v_b$ for any two marks linked by a circuit of the table; the molecules of the table alone are the smallest nonempty sets of marks containing, with each mark, every mark so linked to it (7.4), so v is constant on each of them. □

Theorem 7.16 (The inner moment generating function). *As stated: the even statistic at every gauge, with the basis law and the cobasis law there.*

Proof. For real z and w, $e^{E(z+w)} = \Lambda(z+w)\,\Lambda(-z-w)$. By the first display of the theorem, $\Lambda(z+w)/\Lambda(z) = \mathbb{E}_{T\sim\mathbb{P}_\alpha}[e^{\langle w,\chi_T\rangle}]$, and the same display at the gauge $\alpha^{-1} = e^{-2z}$, whose basis law is $\mathbb{P}_{\alpha^{-1}} = \mathbb{P}^*_\alpha$, gives $\Lambda(-z-w)/\Lambda(-z) = \mathbb{E}_{T'\sim\mathbb{P}^*_\alpha}[e^{-\langle w,\chi_{T'}\rangle}]$. Multiplying, and using the independence of T and T' under $\mathbb{P}_\alpha \otimes \mathbb{P}^*_\alpha$,

$$\frac{e^{E(z+w)}}{e^{E(z)}} = \mathbb{E}_{(T,T')\sim\mathbb{P}_\alpha\otimes\mathbb{P}^*_\alpha}\big[e^{\langle w,\chi_T-\chi_{T'}\rangle}\big], \qquad \chi_T - \chi_{T'} = 2(\mathbf{1}_T - \mathbf{1}_{T'}),$$

which is the display; its logarithm says that $w \mapsto E(z+w) - E(z)$ is the cumulant generating function of $\chi_T - \chi_{T'}$. At $z = 0$, $e^{E(0)} = \Lambda(0)^2 = K(\mathbf{1})^2$ by (i) of 7.15, and $\mathbb{P}^*_{\mathbf{1}} = \mathbb{P}_{\mathbf{1}}$; with w written z this is the display of the reference. □

Remark. The display at a general gauge, and (iii) of 7.15, were checked in exact arithmetic on the table whose bases are the unions of a 2-subset of $\{0,1,2\}$ and a 1-subset of $\{3,4\}$, with arbitrary positive weights (`sweep/s0107/tables.py`).

Corollary 7.24 (Moments and cumulants). *As stated: the joint cumulants of the table at every order; (i) and the cumulants of the components are those of the reference.*

Proof. For a function Y of the index (k,l) write $\mathbb{E}_w[Y] = \sum_{k,l} w_{kl} Y(k,l)$; $\mathbb{E}_w[1] = 1$ by 7.23.

(1) Generating functions. By 7.23 at $x = e^v$, $v \in \mathbb{C}^B$,

$$\mathbb{E}_{T\sim\mathbb{P}_\alpha}\Big[\exp\Big(\sum_{e\in B} v_e X_e\Big)\Big] = \sum_{k,l} w_{kl}\, M_{kl}(v), \qquad M_{kl}(v) = \det\big(I + (D_{e^v} - I)\Pi^{(kl)}_{BB}\big),$$

with $M_{kl}(0) = 1$. So $C_{kl}(v) = \log M_{kl}(v)$ is a power series in v without constant term, and for distinct marks the cumulant $\kappa^{(kl)}(e_1,\dots,e_p)$ of the component is the coefficient of $v_{e_1}\cdots v_{e_p}$ in C_{kl}; the reference computes it by the cyclic formula. The joint cumulant $\kappa_\alpha(e_1,\dots,e_p)$ is the coefficient of $v_{e_1}\cdots v_{e_p}$ in $\log\sum_{k,l} w_{kl} e^{C_{kl}(v)}$, a power series since $\sum_{k,l} w_{kl} = 1$.

(2) Cumulants over the index. Let $(Y_i)_{i\in I}$ be finitely many functions of the index, $\lambda = (\lambda_i)_{i\in I}$ formal variables, and $\mu(\lambda) = \mathbb{E}_w[\exp(\sum_i \lambda_i Y_i)]$, a power series with constant term 1. For $D \subseteq I$ write $\lambda^D = \prod_{i\in D}\lambda_i$; the coefficient of λ^D in μ is $\mathbb{E}_w[\prod_{i\in D} Y_i]$. In $\log\mu = \sum_{j\geq 1} \frac{(-1)^{j-1}}{j}(\mu-1)^j$ the coefficient of λ^I comes from the products of j monomials of $\mu - 1$ without repeated variables and with disjoint supports covering I; each partition $\mathfrak{q}$ of I into j blocks arises from $j!$ such ordered products. So

$$[\lambda^I]\log\mu = \sum_{j\geq 1} \frac{(-1)^{j-1}}{j}\, j! \sum_{|\mathfrak{q}|=j} \prod_{D\in\mathfrak{q}} \mathbb{E}_w\Big[\prod_{i\in D} Y_i\Big] = \kappa_w\big((Y_i)_{i\in I}\big),$$

and, setting the variables outside a subset D to 0, $[\lambda^D]\log\mu = \kappa_w((Y_i)_{i\in D})$.

(3) Substitution. Fix distinct marks $e_1,\dots,e_p$ of B; for nonempty $C \subseteq \{1,\dots,p\}$ put $v^C = \prod_{c\in C} v_{e_c}$ and $Y_C(k,l) = \kappa^{(kl)}(e_C)$, the coefficient of v^C in C_{kl}. Setting the variables v_e with

$e \notin \{e_1, \dots, e_p\}$ to 0 and dropping every monomial divisible by some $v_{e_c}^2$ is a ring homomorphism onto the ring $\mathcal{R}$ of polynomials in $v_{e_1}, \dots, v_{e_p}$ with $v_{e_c}^2 = 0$; it keeps the coefficient of $v_{e_1} \cdots v_{e_p}$ and commutes with exp and log of series without constant term. In $\mathcal{R}$, C_{kl} becomes $\sum_{C \neq \varnothing} Y_C(k,l)\, v^C$, the image of $\sum_C \lambda_C Y_C(k,l)$ under $\lambda_C \mapsto v^C$. So the coefficient of $v_{e_1} \cdots v_{e_p}$ in $\log \sum_{k,l} w_{kl} e^{C_{kl}}$ is that of the image of $\log \mu(\lambda)$, with I the set of nonempty C. A monomial $\prod_C \lambda_C^{n_C}$ maps to $\prod_C (v^C)^{n_C}$, which is $v_{e_1} \cdots v_{e_p}$ exactly when the C with $n_C > 0$ have $n_C = 1$ and form a partition $\mathfrak{p}$ of $\{1, \dots, p\}$, and is 0 or another monomial otherwise. By (2),

$$\kappa_\alpha(e_1, \dots, e_p) = \sum_{\mathfrak{p}} [\lambda^{\mathfrak{p}}] \log \mu = \sum_{\mathfrak{p}} \kappa_w\Big(\big(\kappa^{(kl)}(e_C)\big)_{C \in \mathfrak{p}} \Big).$$

At $p = 1$ the single partition gives $\kappa_\alpha(e) = \mathbb{E}_w[\Pi_{ee}^{(kl)}]$, and $\kappa_\alpha(e) = \mathbb{P}_\alpha(e \in T) = R_e(\alpha)$. Every step is an identity of power series in which the w_{kl} enter linearly inside μ, with $\sum_{k,l} w_{kl} = 1$, so it holds for complex mixing coefficients. □

Remark. At $p = 2$ and $p = 3$ the formula gives $\kappa_\alpha(e,f) = \mathbb{E}_w[\kappa^{(kl)}(e,f)] + \kappa_w(\Pi_{ee}^{(kl)}, \Pi_{ff}^{(kl)})$ and $\kappa_\alpha(e,f,g) = \mathbb{E}_w[\kappa^{(kl)}(e,f,g)] + \sum_3 \kappa_w(\Pi_{ee}^{(kl)}, \kappa^{(kl)}(f,g)) + \kappa_w(\Pi_{ee}^{(kl)}, \Pi_{ff}^{(kl)}, \Pi_{gg}^{(kl)})$, the sum over the three choices of the mark that stands alone: the covariances and the third cumulant over the index of the reference. The formula was checked in exact arithmetic against the generating function of a mixture of three components with complex mixing coefficients for $p = 2, 3, 4, 5$ (`sweep/s0107/cumulants2.py`).

50.8 Chapter 8: families

Proposition 8.11 (The interest over latent vectors). *As stated: every table determinantal over $\mathbb{R}$ or over $\mathbb{C}$, each letter opened with as many latent vectors as its own exponent asks.*

Proof. The masses are real and positive. For a mass $m_e \leq 0$ the interest diverges by 8.5(i), the wall $\kappa_{\{e\}} = m_e - \sum_j \big(s_j d_j(\{e\}) + t_j d_j^*(\{e\})\big)$ being at most m_e, and so does the integral over α_e in step (4).

Fix a table j, write $\mathbb{F} = \mathbb{F}_j$, $\beta = \beta_j$, $r = r_j$, and let $A \in \mathbb{F}^{r \times n}$ be a slice of it: $\det A_T = \boldsymbol{\omega}_T$, so that $|\det A_T|^2 = \theta_{j,T}$ for $T \in \mathcal{B}_j$ and $\det A_T = 0$ for every other set T of r marks (7.20). For a matrix X with n columns write X^{H} for its conjugate transpose, and $D_\alpha = \operatorname{diag}(\alpha)$. Expanding by the maximal minors of X,

$$\det\big(X D_\alpha X^{\mathsf{H}}\big) = \sum_W |\det X_W|^2\, \alpha^W,$$

the sum over the sets W of as many marks as X has rows; this is the expansion behind 7.21, and with $X = A$ it gives $K_j(\alpha) = \det(A D_\alpha A^{\mathsf{H}})$. So $K_j(\mathbf{1}) = \det(AA^{\mathsf{H}}) > 0$, A has rank r, and its row space $V_j = \{A^{\mathsf{H}} y :\ y \in \mathbb{F}^r\}$, the space onto which $\Pi^{(11)}$ of 7.23 projects, has dimension r over $\mathbb{F}$.

(1) The basis letter. The matrix $\hat{A} = (AA^{\mathsf{H}})^{-1/2} A$ has orthonormal rows and $\{\hat{A}^{\mathsf{H}} y\} = V_j$, and $\det \hat{A}_T = \det(AA^{\mathsf{H}})^{-1/2} \det A_T$. So $\theta_{j,T} = K_j(\mathbf{1})\, |\det \hat{A}_T|^2$ and $K_j(\alpha) = K_j(\mathbf{1}) \det(\hat{A} D_\alpha \hat{A}^{\mathsf{H}})$.

(2) The cobasis letter. Choose $\hat{C} \in \mathbb{F}^{(n-r) \times n}$ with orthonormal rows and $\{\hat{C}^{\mathsf{H}} y\} = V_j^{\perp}$, the orthogonal complement for the form $\sum_e u_e \overline{v_e}$. Then $\hat{A}\hat{C}^{\mathsf{H}} = 0$, and the square matrix U whose rows are those of $\hat{A}$ followed by those of $\hat{C}$ is unitary. For an invertible matrix, $\det U[I,J] = \pm \det U \cdot \det U^{-1}[J^c, I^c]$ for every set I of rows and set J of columns of equal size; with $U^{-1} = U^{\mathsf{H}}$ and $|\det U| = 1$ this gives $|\det U[I,J]| = |\det U[I^c, J^c]|$. With I the rows of $\hat{A}$ and $J = T$,

$|\det \hat{C}_{\mathcal{E}\setminus T}| = |\det \hat{A}_T|$ for every set T of r marks. The expansion above, for $X = \hat{C}$ and the sets $W = \mathcal{E} \setminus T$, gives

$$\det\big(\hat{C} D_\alpha \hat{C}^{\mathsf{H}}\big) = \sum_T |\det \hat{A}_T|^2 \alpha^{\mathcal{E}\setminus T} = \frac{1}{K_j(\mathbf{1})} \sum_{T \in \mathcal{B}_j} \theta_{j,T}\, \alpha^{\mathcal{E}\setminus T} = \frac{\Psi_j(\alpha)}{K_j(\mathbf{1})}.$$

(3) The Gaussian opening. For a Hermitian positive definite matrix G of size d over $\mathbb{F}$, a unitary change of variables, which keeps the Lebesgue measure of $\mathbb{F}^d \cong \mathbb{R}^{\beta d}$, makes G diagonal, and $\int_{\mathbb{F}} e^{-\lambda|z|^2} dz = (\pi/\lambda)^{\beta/2}$ for $\lambda > 0$; so $\int_{\mathbb{F}^d} e^{-z^{\mathsf{H}} G z} dz = \pi^{\beta d/2} \det(G)^{-\beta/2}$. For an integer $k \geq 0$ and $s = \beta k/2$ it follows that

$$\det(G)^{-s} = \pi^{-ds} \int_{(\mathbb{F}^d)^k} \exp\Big(-\sum_{i=1}^{k} z_i^{\mathsf{H}} G z_i \Big)\, dz_1 \cdots dz_k.$$

Take $G = \hat{A} D_\alpha \hat{A}^{\mathsf{H}}$, $d = r$ and $k = 2s_j/\beta$. The map $z \mapsto x = \hat{A}^{\mathsf{H}} z$ is an $\mathbb{F}$-linear isometry of $\mathbb{F}^r$ onto V_j, so it carries the Lebesgue measure of $\mathbb{F}^r$ to that of V_j, and $z^{\mathsf{H}} \hat{A} D_\alpha \hat{A}^{\mathsf{H}} z = \sum_e \alpha_e |x_e|^2$. With step (1),

$$K_j(\alpha)^{-s_j} = K_j(\mathbf{1})^{-s_j} \pi^{-r_j s_j} \int_{V_j^{2s_j/\beta}} \exp\Big(-\sum_{i,e} \alpha_e |(x_{j,i})_e|^2 \Big) \prod_i dx_{j,i},$$

and in the same way, with step (2), $G = \hat{C} D_\alpha \hat{C}^{\mathsf{H}}$, $d = n - r_j = r_j^*$ and $k = 2t_j/\beta$,

$$\Psi_j(\alpha)^{-t_j} = K_j(\mathbf{1})^{-t_j} \pi^{-r_j^* t_j} \int_{(V_j^\perp)^{2t_j/\beta}} \exp\Big(-\sum_{i,e} \alpha_e |(x^*_{j,i})_e|^2 \Big) \prod_i dx^*_{j,i}.$$

An exponent 0 asks for no vectors, and the formula then reads $1 = 1$.

(4) The scales. Multiplying over j, with $c_F = \prod_j K_j(\mathbf{1})^{s_j + t_j} \pi^{r_j s_j + r_j^* t_j}$,

$$W(\alpha) = \frac{1}{c_F} \int \exp\Big(-\sum_e \alpha_e \mathfrak{q}_e \Big) \prod_{j,i} dx_{j,i}\, dx^*_{j,i}.$$

Insert this into $J_F(\mathbf{m};\mathbf{s},\mathbf{t}) = \int \alpha^{\mathbf{m-1}} e^{-|\alpha|} W(\alpha)\, d\alpha$. Every integrand is nonnegative, so the integrals may be taken in either order, and

$$\int_0^\infty \alpha_e^{m_e - 1} e^{-\alpha_e(1+\mathfrak{q}_e)}\, d\alpha_e = \Gamma(m_e)\,(1+\mathfrak{q}_e)^{-m_e}.$$

Integrating the scales first gives the right side of the statement, and integrating the latent vectors first gives $J_F(\mathbf{m};\mathbf{s},\mathbf{t})$: both are the integral of one nonnegative function, finite or infinite together.

(5) The Breta law. Where the two sides are finite, the function

$$f(\alpha, x, x^*) = \alpha^{\mathbf{m-1}} \exp\Big(-\sum_e \alpha_e (1 + \mathfrak{q}_e) \Big)$$

is integrable, with integral $c_F J_F(\mathbf{m};\mathbf{s},\mathbf{t})$ by step (4). Integrating out the latent vectors, its marginal in α is $c_F\, \alpha^{\mathbf{m-1}} e^{-|\alpha|} W(\alpha)$, proportional to the density $\alpha^{\mathbf{m-1}} e^{-|\alpha|} W(\alpha)/J_F(\mathbf{m};\mathbf{s},\mathbf{t})$ of $\mathrm{Breta}(F;\mathbf{m};\mathbf{s},\mathbf{t})$ (8.10; the interest is finite exactly when every wall is positive, 8.5(i)). Given the latent vectors, f is the product over the marks of $\alpha_e^{m_e-1} e^{-\alpha_e(1+\mathfrak{q}_e)}$: the scales are independent, and $\alpha_e(1+\mathfrak{q}_e)$ has the density $u^{m_e-1}e^{-u}/\Gamma(m_e)$ on $(0,\infty)$, the law Gamma_{m_e}.

(6) Equal exponents over $\mathbb{R}$. If $\mathbb{F}_j = \mathbb{R}$ and $s_j = t_j$, the vectors of the two letters come in pairs $(x_{j,i}, x^*_{j,i})$, $i \le 2s_j$. The map $V_j \times V_j^\perp \to \mathbb{R}^{\mathcal{E}}$, $(x, x^*) \mapsto x + x^*$, is a linear isometry, so it carries the product of the Lebesgue measures to that of $\mathbb{R}^{\mathcal{E}}$, and for $u = x + x^*$, $x = \mathrm{pr}_j u$ and $x^* = (I - \mathrm{pr}_j)u$. The constant of table j is then $K_j(\mathbf{1})^{2s_j}\pi^{ns_j}$. □

Remark. The reference, proof of 8.11, treats $s_j = t_j = k_j/2$ over $\mathbb{R}$ and opens the two letters of table j with one set of k_j vectors $u = \hat{A}^{\mathsf{T}} y + \hat{C}^{\mathsf{T}} y^*$; that is step (6). In the proof above each letter is opened on its own space, with as many vectors as its exponent asks, and over $\mathbb{C}$ by the complex Gaussian integral, $\beta = 2$.

Lemma S3. *For a family on $\mathcal{E}$ and a nonempty set $S \subseteq \mathcal{E}$, $c_j(S) = 0$ for every table j of the family exactly when S is a union of molecules.*

Proof. The molecules are the smallest nonempty sets of marks that contain, with each mark, every mark linked to it (7.4); so a set of marks with that property is a union of molecules, and a union of molecules has it.

Let S be a union of molecules. By 7.9 every table is the direct sum of its restrictions to the molecules: its bases are the unions of one basis of each restriction, and a basis of the restriction to a molecule M has $r_j(M)$ marks (7.5). So $|T \cap S| = \sum_{M \subseteq S} r_j(M)$ on every basis T of table j, and by 7.13, $d_j(S) = r_j(S)$, that is $c_j(S) = 0$.

Let S not be a union of molecules. Then some $e \in S$ is linked to some $f \notin S$: e and f lie in a common circuit of some table j. By 7.7 some basis T of table j has $e \in T$, $f \notin T$ and $T' = (T \setminus \{e\}) \cup \{f\}$ a basis. Then $|T' \cap S| = |T \cap S| - 1$, so $|T \cap S|$ takes two values on the bases of table j, and $c_j(S) \ge 1$ by 7.13. □

Remark. Since the weight law charges every basis, Lemma S3 is the first sentence of 13.9 read on the bases: $\mathrm{Var}_{T \sim \mathbb{P}_{j,\mathbf{1}}} |T \cap U| = 0$ exactly when $|T \cap U|$ is constant on $\mathcal{B}_j$, that is when $c_j(U) = 0$.

Proposition 8.16 (The wall of a compound). *As stated: the identity holds for every nonempty proper S, and only the tables with $\sigma_j \neq 0$ enter it.*

Proof. 8.13 gives, as identities of functions of the data, $\kappa_S + \kappa_S^{\mathrm{top}} = 2\sum_j \sigma_j c_j(S)$ and $\kappa_{\mathcal{E}\setminus S} = \kappa_{\mathcal{E}} + \kappa_S^{\mathrm{top}}$. Adding the two,

$$\kappa_S + \kappa_{\mathcal{E}\setminus S} = \kappa_{\mathcal{E}} + 2\sum_j \sigma_j c_j(S).$$

If $c_j(S) = 0$ in every table with $\sigma_j \neq 0$, the sum vanishes and $\kappa_S + \kappa_{\mathcal{E}\setminus S} = \kappa_{\mathcal{E}}$; this holds in particular when S is a union of molecules, where $c_j(S) = 0$ in every table (Lemma S3). On the balance wall $\kappa_{\mathcal{E}} = 0$, so $\mathrm{Re}\,\kappa_S + \mathrm{Re}\,\kappa_{\mathcal{E}\setminus S} = 0$ and one of the two walls has real part at most zero. By 8.7 the period converges only where every nonempty proper wall has positive real part, so it diverges. □

Remark. The reference, 8.16, takes $c_j(S) = 0$ in every table. With complex exponents a table with $s_j = -t_j \neq 0$ is active and has $\sigma_j = 0$; it does not enter the identity.

Definition 8.17 (Target; native gauge). As stated: the target for all data with $m_{\mathcal{E}} \neq 0$ and on the balance wall, and native points of $(\mathbb{C}^\times)^{\mathcal{E}}$ off the zeros of the letters, the native gauges being the native points in $\mathbb{R}^{\mathcal{E}}_{>0}$.

Proof. The definition is consistent.

(1) Scale. K_j and Ψ_j are homogeneous polynomials of degrees r_j and $r_j^* = n - r_j$, every basis having r_j marks and every complement $n - r_j$ (7.1). So for $c \in \mathbb{C}^\times$, $K_j(c\alpha) = c^{r_j} K_j(\alpha)$ and $(\partial_e K_j)(c\alpha) = c^{r_j - 1}(\partial_e K_j)(\alpha)$, whence $R_{j,e}(c\alpha) = R_{j,e}(\alpha)$ wherever $K_j(\alpha) \neq 0$, and likewise $R^*_{j,e}(c\alpha) = R^*_{j,e}(\alpha)$ wherever $\Psi_j(\alpha) \neq 0$. The condition $K_j(\alpha)\Psi_j(\alpha) \neq 0$ is unchanged by scaling and the target does not involve the point, so the usage, and with it nativity, is a property of the point up to scale.

(2) The two clauses of the target. On the balance wall $m_{\mathcal{E}} = \sum_j (s_j r_j + t_j r_j^*)$ (8.1); where this is not zero the formula gives $\boldsymbol{\tau} = \mathbf{m}$, the value assigned on the balance wall. So the two clauses agree where both apply, and the second also covers the balance wall with $m_{\mathcal{E}} = 0$.

(3) Positive points. At $\alpha \in \mathbb{R}^{\mathcal{E}}_{>0}$ the letters are positive, the weights being positive, so every positive point lies off their zeros, and $R_{j,e}(\alpha) = \mathbb{P}_{j,\alpha}(e \in T)$ and $R^*_{j,e}(\alpha) = \mathbb{P}^*_{j,\alpha}(e \notin T)$ (7.16). □

Remark. The direction of a ray lies on the balance wall (38.1), so its target is its masses $\mathbf{m}_1$, and the native gauges at complex points of the direction are the points α_c of the letter complement with $c^{(1)}(\alpha_c) = 0$: the native gauges of the ray (38.4).

Theorem 8.19 (The native gauge is the saddle). *As stated, with the native gauges of Definition 8.17.*

Proof. At a gauge $\alpha = e^y$ the usage of Definition 8.17 is $\nabla\Phi(y)$: by the chain rule $\partial_{y_e} \log K_j(e^y) = \alpha_e \partial_e K_j(\alpha)/K_j(\alpha) = R_{j,e}(\alpha)$ and $\partial_{y_e} \log \Psi_j(e^y) = R^*_{j,e}(\alpha)$, and Φ is $\sum_j \left(s_j \log K_j + t_j \log \Psi_j\right)$ read at e^y (8.18). For real data with $s_j, t_j \geq 0$, not all zero, and $\mathbf{m} > 0$, $m_{\mathcal{E}} > 0$, so the target of that definition is the one given by its formula, and its native gauges are the gauges of (i). With this reading the statement is the reference, proof of 8.19. □

Proposition 8.20 (The native gauges of a compound). *As stated: the weights need not factor except in the sentence on products, and the molecules are those of the active family.*

Proof. Write $g = \sum_j (s_j d_j + t_j d_j^*)$. An inactive table enters neither the potential, nor the target, nor g, nor the Newton sum $\mathcal{N}_F$, its terms carrying the factor zero; every statement below concerns the active family, whose molecules are $\mathcal{E}_1, \ldots, \mathcal{E}_q$.

(1) The criterion of the saddle. By 8.19(ii) a native gauge exists exactly when $\boldsymbol{\tau}$ lies in the relative interior of $\mathcal{N}_F = \sum_j (s_j P_j + t_j P_j^*)$, and it is then unique modulo the space V of directions along which Φ is affine. By 8.19(iii), whose first sentence uses no connectedness, $\mathcal{N}_F = \{x : \ x_{\mathcal{E}} = g(\mathcal{E}),\ x_S \geq g(S) \text{ for all } S\}$.

(2) The extent of x_S on $\mathcal{N}_F$. The least value of a linear function on a Minkowski sum with nonnegative coefficients is the same sum of its least values on the summands. The least value of x_S on $P_j = \operatorname{conv}\{\mathbf{1}_T\}$ is $\min_T |T \cap S| = d_j(S)$, and on $P_j^* = \operatorname{conv}\{\mathbf{1}_{\mathcal{E}\setminus T}\}$ it is $\min_T |S \setminus T| = d_j^*(S)$ (7.13). So the least value of x_S on $\mathcal{N}_F$ is $g(S)$, and that of $x_{\mathcal{E}\setminus S}$ is $g(\mathcal{E} \setminus S)$; since $x_{\mathcal{E}} = g(\mathcal{E})$ on $\mathcal{N}_F$ and $\mathcal{N}_F$ is convex, x_S takes on $\mathcal{N}_F$ exactly the values of $[g(S),\ g(\mathcal{E}) - g(\mathcal{E} \setminus S)]$. At any masses $\kappa_S + \kappa_{\mathcal{E}\setminus S} - \kappa_{\mathcal{E}} = g(\mathcal{E}) - g(S) - g(\mathcal{E} \setminus S)$, the masses cancelling, so by 8.16 the length of this interval is $2\sum_j \sigma_j c_j(S) = \sum_j (s_j + t_j) c_j(S)$.

(3) The relative interior. An active table has $s_j + t_j > 0$. So the interval of step (2) is a point exactly when $c_j(S) = 0$ for every active table, that is, by Lemma S3 applied to the active family, when S is a union of the $\mathcal{E}_i$. The relative interior of a polyhedron given by linear equalities and inequalities consists of its points at which every inequality that is not an equality on the whole polyhedron holds strictly. So $\boldsymbol{\tau}$ lies in the relative interior of $\mathcal{N}_F$ exactly when $\tau_S = g(S)$ for every union S of the $\mathcal{E}_i$ and $\tau_S > g(S)$ for every other nonempty S.

(4) Molecule by molecule. By 7.9 for the active family, every active table is the direct sum of its restrictions to the $\mathcal{E}_i$, its bases being the unions of one basis of each restriction. Taking the least of $|T\cap S|$, and of $|S\setminus T|$, restriction by restriction, $d_j(S)=\sum_i d_j(S\cap\mathcal{E}_i)$ and $d_j^*(S)=\sum_i d_j^*(S\cap\mathcal{E}_i)$ for every active j; so $g(S)=\sum_i g(S\cap\mathcal{E}_i)$ and $\tau_S-g(S)=\sum_i\big(\tau_{S\cap\mathcal{E}_i}-g(S\cap\mathcal{E}_i)\big)$. Hence the conditions of step (3) hold exactly when $\tau_{\mathcal{E}_i}=g(\mathcal{E}_i)$ for every i and $\tau_S>g(S)$ for every S with $\varnothing\neq S\subsetneq\mathcal{E}_i$ for some i: given these, a union of the $\mathcal{E}_i$ has $\tau_S-g(S)=0$, and any other nonempty S meets some $\mathcal{E}_i$ in a nonempty proper subset, whose term is positive while the others are nonnegative; conversely each $\mathcal{E}_i$ is a union of the $\mathcal{E}_i$, and a nonempty proper subset of one $\mathcal{E}_i$ is not. Since $c_j(\mathcal{E}_i)=0$ for every active j, $d_j(\mathcal{E}_i)=r_j(\mathcal{E}_i)$, so $r_j(\mathcal{E}\setminus\mathcal{E}_i)=r_j-r_j(\mathcal{E}_i)$ (7.12, $d_j(S)=r_j-r_j(\mathcal{E}\setminus S)$) and $d_j^*(\mathcal{E}_i)=|\mathcal{E}_i|-r_j(\mathcal{E}_i)=r_j^*(\mathcal{E}_i)$. So $g(\mathcal{E}_i)=\sum_j\big(s_jr_j(\mathcal{E}_i)+t_jr_j^*(\mathcal{E}_i)\big)$, and the conditions are the balance of every $\mathcal{E}_i$ at the target and the positivity of its proper walls there. This proves the criterion.

(5) The free scales. By 7.17 the second derivative of $\log K_j(e^y)$ along a direction v is the variance of $\langle v,\mathbf{1}_T\rangle$ under $\mathbb{P}_{j,e^y}$, and that of $\log\Psi_j(e^y)=\langle\mathbf{1},y\rangle+\log K_j(e^{-y})$ (7.2) is the variance of $\langle v,\mathbf{1}_T\rangle$ under $\mathbb{P}_{j,e^{-y}}$. Both laws charge every basis, so each variance vanishes exactly when $\langle v,\mathbf{1}_T\rangle$ is constant over $\mathcal{B}_j$. The second derivative of Φ along v is the sum of these variances with the coefficients $s_j,t_j\geq 0$, and every active table has a positive coefficient; so Φ is affine along v exactly when $\langle v,\mathbf{1}_T\rangle$ is constant over the bases of every active table. By 7.8 for the active family such a v is constant on every $\mathcal{E}_i$. Conversely, if v is constant on every $\mathcal{E}_i$, with value v_i, then $\langle v,\mathbf{1}_T\rangle=\sum_i v_i|T\cap\mathcal{E}_i|=\sum_i v_ir_j(\mathcal{E}_i)$ on every basis of an active table j, by step (4). So $V=\operatorname{span}\{\mathbf{1}_{\mathcal{E}_1},\dots,\mathbf{1}_{\mathcal{E}_q}\}$, and the native gauges are the gauges $e^v\alpha^\star$, $v\in V$: the gauges β with $\beta/\alpha^\star$ constant on every $\mathcal{E}_i$.

(6) Factoring weights. When the weights factor across the $\mathcal{E}_i$, the letters of every active table factor,

$$K_j(\alpha)=\prod_i K_{j,i}(\alpha_{\mathcal{E}_i}),\qquad \Psi_j(\alpha)=\prod_i\Psi_{j,i}(\alpha_{\mathcal{E}_i}),$$

with the Foreman polynomials of the restrictions (7.9). So $\Phi(y)=\sum_i\Phi_i(y_{\mathcal{E}_i})$, with Φ_i the potential of the restriction of the family to $\mathcal{E}_i$, and the condition $\nabla\Phi=\boldsymbol{\tau}$ splits into the conditions $\nabla\Phi_i=\boldsymbol{\tau}|_{\mathcal{E}_i}$, each the native condition of the restriction to $\mathcal{E}_i$ at the masses $\boldsymbol{\tau}|_{\mathcal{E}_i}$, which lie on its balance wall by step (4), so that its target is $\boldsymbol{\tau}|_{\mathcal{E}_i}$ (8.17). The native gauges are the gauges whose restriction to every $\mathcal{E}_i$ is native there: the products of native gauges of the molecules.

(7) Units. A loop is a circuit by itself, so it lies in no other circuit; and a coloop e lies in no circuit, since a circuit C through e would lie in every basis containing the independent set $C\setminus\{e\}$, such a basis containing e, while a circuit lies in no basis. So a mark e that is a loop or a coloop in every table is linked to no other mark, and $\{e\}$ is a unit. Every basis of table j contains e, or none does, so $K_j(\alpha)=\alpha_e^{\epsilon_j}\tilde K_j(\alpha_{\mathcal{E}\setminus e})$ and $\Psi_j(\alpha)=\alpha_e^{1-\epsilon_j}\tilde\Psi_j(\alpha_{\mathcal{E}\setminus e})$ with $\epsilon_j\in\{0,1\}$: the letters of $\{e\}$ are monomials. □

Remark. The criterion is stated for the molecules of the active family because linking (7.4) runs through the circuits of every table, while an inactive table enters neither the potential, nor the target, nor the walls. So a molecule of the family may join several molecules of the active family, and then a proper wall of that molecule vanishes at the target although a native gauge exists. For instance, on $\mathcal{E}=\{1,2,3,4\}$ let the list with the bases $\{1,3\},\{1,4\},\{2,3\},\{2,4\}$ carry $(s,t)=(1,0)$ and the list $\binom{\mathcal{E}}{1}$ carry $(0,0)$, with the masses $\frac12\mathbf{1}$ on the balance wall. Through the second table $\mathcal{E}$ is one molecule of the family, while the active family has the molecules $\{1,2\}$ and $\{3,4\}$. Every mark lies in half of the bases of the first table, so the gauge $\mathbf{1}$ is native, and the wall at $\{1,2\}$ is $\tau_{\{1,2\}}-d_1(\{1,2\})=1-1=0$.

Remark. At the centre of 8.21 the gauge **1** is native, and step (5) shows that the native gauges are the gauges constant on every molecule of the active family: this is the uniqueness clause of 8.21(i).

50.9 Chapter 9: realizations and the still

Proposition 9.2 (A realization sits on a wall only along its molecules). *As stated, for every family.*

Proof. (1) The walls as expectations. By 7.16, $R_{j,e}(\alpha) = \mathbb{P}_{j,\alpha}(e \in T)$ and $R^*_{j,e}(\alpha) = \mathbb{P}^*_{j,\alpha}(e \notin T)$. Summing the usage over $e \in S$,

$$m_S = \sum_j \Big(s_j \mathbb{E}_{T\sim\mathbb{P}_{j,\alpha}}[N_S] + t_j \mathbb{E}_{T\sim\mathbb{P}^*_{j,\alpha}}\big[|S| - N_S\big] \Big),$$

and with $d^*_j(S) = |S| - r_j(S)$ (7.12) the wall $\kappa_S = m_S - \sum_j \big(s_j d_j(S) + t_j d^*_j(S)\big)$ is the displayed sum.

(2) The sign. By 7.13, $d_j(S) \le N_S \le r_j(S)$ on every basis of table j. So both brackets are nonnegative, and so is κ_S, the exponents being nonnegative.

(3) Equality. The laws $\mathbb{P}_{j,\alpha}(T) = \theta_{j,T}\alpha^T/K_j(\alpha)$ and $\mathbb{P}^*_{j,\alpha}(T) = \theta_{j,T}\alpha^{\mathcal{E}\setminus T}/\Psi_j(\alpha)$ charge every basis. So the first bracket of table j vanishes exactly when $N_S = d_j(S)$ on every basis, and the second exactly when $N_S = r_j(S)$ on every basis; since the values of N_S fill $\{d_j(S), \dots, r_j(S)\}$ (7.13), each happens exactly when $c_j(S) = 0$. Every table has $s_j > 0$ or $t_j > 0$, so $\kappa_S = 0$ exactly when $c_j(S) = 0$ for every table, that is, by Lemma S3, when S is a union of molecules.

(4) The last sentence. $\mathcal{E}$ is a union of molecules, so $\kappa_{\mathcal{E}} = 0$. At a realization every table is active, so the family is connected (8.1) exactly when no nonempty proper S has $c_j(S) = 0$ for every table, that is, by Lemma S3, when no nonempty proper set is a union of molecules; then every proper wall is positive by step (3). □

Remark. The reference, proof of 9.2, has steps (1) and (2) and the positivity of the bracket of an active table with $c_j(S) \ge 1$, which connectedness supplies for every nonempty proper S. Step (3) reads off the equality case, which holds for every family.

Proposition 9.3 (Masses at a gauge). *As stated, at every gauge e^{y_0}.*

Proof. By 9.1 the masses are $\tau_e = \sum_j \big(s_j R_{j,e}(\alpha) + t_j R^*_{j,e}(\alpha)\big)$, with $R_{j,e} = \alpha_e \partial_e K_j/K_j$ the occupation and $R^*_{j,e} = \alpha_e \partial_e \Psi_j/\Psi_j$ the dual occupation, and $R^*_{j,e}(\alpha) = 1 - R_{j,e}(\alpha^{-1})$ (7.16). At $\alpha = e^{y_0}$ this is the first expression. Put $a_j = R_{j,e}(e^{y_0})$ and $b_j = R_{j,e}(e^{-y_0})$, so that $R^{\pm}_{j,e} = \frac{1}{2}(a_j \pm b_j)$. With $s_j = \sigma_j + \delta_j$ and $t_j = \sigma_j - \delta_j$,

$$s_j a_j + t_j(1 - b_j) = \sigma_j(1 + a_j - b_j) + \delta_j(a_j + b_j - 1) = \sigma_j(1 + 2R^-_{j,e}) + \delta_j(2R^+_{j,e} - 1).$$

At $y_0 = 0$, $a_j = b_j = R_{j,e}(\mathbf{1})$: $R^-_{j,e} = 0$ and $R^+_{j,e} = R_{j,e}(\mathbf{1})$. □

Remark. By 7.17, $R_{j,e}(e^y) = \partial_{y_e} \log K_j(e^y)$, whose Taylor series at 0 is

$$\sum_{i\ge 0} \frac{1}{i!} \sum_{u\in\mathcal{E}^i} \kappa_{j,\mathbf{1}}(e,u) \prod_{l=1}^{i} y_{u_l}$$

in its domain of convergence, as in 9.6. At $y = \pm y_0$ the term of order i carries $(\pm 1)^i$, so $R^+_{j,e}$ collects the terms of even order and $R^-_{j,e}$ those of odd order. Rung one at a deviation has the

parity of the odd rungs of 9.6, σ_j with the odd part of the occupations and δ_j with the even part, besides the constant $\sum_j(\sigma_j-\delta_j)=\sum_j t_j$.

Proposition 9.5 (The potential of a compound splits by molecules). *As stated; the last sentence is new.*

Proof. The first two sentences are the reference, proof of 9.5. Let e be a loop or a coloop in every table. By 8.20 $\{e\}$ is a unit, and every basis of table j contains e, or none does, so $K_j(\alpha)=\alpha_e^{\epsilon_j}\tilde K_j(\alpha_{\mathcal E\setminus e})$ and $\Psi_j(\alpha)=\alpha_e^{1-\epsilon_j}\tilde\Psi_j(\alpha_{\mathcal E\setminus e})$ with $\epsilon_j\in\{0,1\}$. So $\Phi(y)=\sum_j\big(s_j\epsilon_j+t_j(1-\epsilon_j)\big)y_e$ plus a function of $y_{\mathcal E\setminus e}$ (8.18), every derivative of Φ of order at least two that involves y_e vanishes, every entry of the still on a string through e is zero, and rung one at e is the constant $\sum_j\big(s_j\epsilon_j+t_j(1-\epsilon_j)\big)$, the mass of e (9.4). The same holds for the two parts $\Phi_{\mathbf E}$ and $\Phi_{\mathbf O}$, which are $\sum_j\sigma_j\log(K_j\Psi_j)$ and $\sum_j\delta_j\log(K_j/\Psi_j)$ read at e^y. □

Proposition 9.10 (Occupations at a gauge). *As stated, at every gauge e^{y_0}.*

Proof. By 9.4, $\varphi_e^{\mathbf X}(0)=\partial_{y_e}\Phi_{\mathbf X}(\log\alpha)$, and by 8.18, $\Phi_{\mathbf E}(y)=\sum_j\sigma_j\big(\log K_j(e^y)+\log\Psi_j(e^y)\big)$ and $\Phi_{\mathbf O}(y)=\sum_j\delta_j\big(\log K_j(e^y)-\log\Psi_j(e^y)\big)$. By 8.19, $\partial_{y_e}\log K_j(e^y)=R_{j,e}$ and $\partial_{y_e}\log\Psi_j(e^y)=R^*_{j,e}$, and $R^*_{j,e}(\alpha)=1-R_{j,e}(\alpha^{-1})$ (7.16). At $\alpha=e^{y_0}$, with $a_j=R_{j,e}(e^{y_0})$ and $b_j=R_{j,e}(e^{-y_0})$,

$$\varphi_e^{\mathbf E}(0)=\sum_j\sigma_j(a_j+1-b_j)=\sum_j\sigma_j(1+2R^-_{j,e}),$$
$$\varphi_e^{\mathbf O}(0)=\sum_j\delta_j(a_j-1+b_j)=\sum_j\delta_j(2R^+_{j,e}-1).$$

At $\alpha=\mathbf 1$, $R^-_{j,e}=0$ and $R^+_{j,e}=R_{j,e}(\mathbf 1)$. The two parts add to the mass of 9.3. □

50.10 Chapter 10: the reading, classes, atoms

Proposition 10.2 (A view through the patterns). *As stated; the inclusion laws are read at every gauge.*

Proof. The expression of the views through $K_{j;e,\mathbf g}$ and $\Psi_{j;e,\mathbf g}$ and the closing sentence on one table are proved in the reference, proof of 10.2. What follows is the expansion at a gauge α and its reading at the table's gauge. Since $\prod_{i\in p}(1+x_i)=\sum_{A\subseteq p}x^A$,

$$K_{j;e,\mathbf g}(\mathbf 1+x)=\sum_p\vartheta^K_{j,p}\sum_{A\subseteq p}x^A=\sum_A x^A\sum_{p\supseteq A}\vartheta^K_{j,p},$$
$$\sum_{p\supseteq A}\vartheta^K_{j,p}=\sum_{T:\ p(T)\supseteq A}\theta_{j,T}\alpha^T=K_j(\alpha)\,\mathbb P_{j,\alpha}\big(p(T)\supseteq A\big),$$

the basis law at α being $\mathbb P_{j,\alpha}(T)=\theta_{j,T}\alpha^T/K_j(\alpha)$ (7.16). Likewise $(\mathbf 1+x)^{\bar p}=\prod_{i\notin p}(1+x_i)=\sum_{A\cap p=\varnothing}x^A$, so

$$\Psi_{j;e,\mathbf g}(\mathbf 1+x)=\sum_A x^A\sum_{p\cap A=\varnothing}\vartheta^\Psi_{j,p},$$
$$\sum_{p\cap A=\varnothing}\vartheta^\Psi_{j,p}=\sum_{T:\ p(T)\cap A=\varnothing}\theta_{j,T}\alpha^{\mathcal E\setminus T}=\Psi_j(\alpha)\,\mathbb P^*_{j,\alpha}\big(p(T)\cap A=\varnothing\big),$$

with $\mathbb{P}^*_{j,\alpha}(T) = \theta_{j,T}\alpha^{\mathcal{E}\setminus T}/\Psi_j(\alpha)$. So the polynomials $K_{j;e,\mathbf{g}}$ and $\Psi_{j;e,\mathbf{g}}$, and with them the view, are determined by $K_j(\alpha)$, $\Psi_j(\alpha)$ and the joint inclusion laws of $e, g_1, \dots, g_k$ under $\mathbb{P}_{j,\alpha}$ and $\mathbb{P}^*_{j,\alpha}$. At $\alpha = \mathbf{1}$, $\alpha^T = \alpha^{\mathcal{E}\setminus T} = 1$: $\vartheta^K_{j,p} = \vartheta^\Psi_{j,p} = \vartheta_{j,p}$, both laws are the weight law (7.16), and $x^{\bar{p}} = x^{\{0,\dots,k\}}(x^{-1})^p$ gives $\Psi_{j;e,\mathbf{g}}(x) = x^{\{0,\dots,k\}}K_{j;e,\mathbf{g}}(x^{-1})$. □

Proposition 10.8 (Computing the classes). *As stated; at a gauge α the identities have their coefficients in the field generated by the weights and the coordinates of α.*

Proof. The steps of the computation compare views and writings, as in the reference, proof of 10.8; only the field is new. Let k be the field generated by the weights and the coordinates of α. By 10.2, a view is the pair $\sum_j \sigma_j \log(K_{j;e,\mathbf{g}}\Psi_{j;e,\mathbf{g}})$, $\sum_j \delta_j \log(K_{j;e,\mathbf{g}}/\Psi_{j;e,\mathbf{g}})$ in $x_i = e^{v_i}$, and the coefficients $\vartheta^K_{j,p} = \sum_{T:\,p} \theta_{j,T}\alpha^T$ and $\vartheta^\Psi_{j,p} = \sum_{T:\,p} \theta_{j,T}\alpha^{\mathcal{E}\setminus T}$ of these polynomials are polynomials with integer coefficients in the weights and the coordinates of α, so they lie in k. Factor every $K_{j;e,\mathbf{g}}$ and $\Psi_{j;e,\mathbf{g}}$ into irreducible polynomials over k. Each factor of a polynomial positive on the orthant vanishes nowhere on it and so has constant sign there, and it is normalized to the value 1 at $x = \mathbf{1}$ by a constant of k. Two different normalized polynomials irreducible over k have no common factor over $\mathbb{C}$, the greatest common divisor of two polynomials over k being their greatest common divisor over $\mathbb{C}$. So the factors over $\mathbb{C}$ of 10.6 are the factors over $\mathbb{C}$ of the factors over k, and a factor over $\mathbb{C}$ divides exactly one normalized factor over k. If two views carry over $\mathbb{C}$ the same factors with the same pairs of exponents, a factor over k of one and a factor over k of the other that share a factor over $\mathbb{C}$ are equal, and comparing the exponents of that shared factor gives equal pairs of exponents. So by 10.6 two views, or two writings, are equal exactly when they carry the same normalized polynomials irreducible over k with the same pairs of exponents: every step is an identity in $k[x]$. At $\alpha = \mathbf{1}$, k is the field generated by the weights, $\mathbb{Q}$ for rational weights, and the coefficients are integers for lists. □

Proposition 10.9 (Masses and occupations on a class). *As stated; the first sentence holds for each of the two parts of the mass.*

Proof. By 9.4, $\varphi^{\mathbf{X}}_e(0) = \partial_{y_e}\Phi_{\mathbf{X}}(\log\alpha)$ is the part $\mathbf{X}$ of rung one, and $\tau_e(\Upsilon) = \partial_{y_e}\Phi(\log\alpha) = \varphi^{\mathbf{E}}_e(0) + \varphi^{\mathbf{O}}_e(0)$. By 10.3(iii) the reading of e determines its self-line functions $\varphi^{\mathbf{E}}_e$ and $\varphi^{\mathbf{O}}_e$, hence their values at 0, and the classes are the level sets of the reading (10.1). So the two parts, and their sum, are constant on every class. For a family whose weights factor across its molecules, $\Phi_{\mathbf{X}}$ is the sum of the potentials of the restrictions to the molecules (9.5), so $\varphi^{\mathbf{X}}_e(0)$ is the same in the family and in the realization of the molecule of e, on which its classes are read. Items (i) and (ii) are proved in the reference, proof of 10.9. □

50.11 Chapter 11: lean, gauge and label

Lemma 11.11 (No degenerate pair). *As stated, at every realization of every family, with the equality case.*

Proof. (1) A sum of covariances. By 9.4 and 8.18, $\kappa^{\mathbf{E}}_\Upsilon(e,f) = 4\sum_j \sigma_j\big(\partial_{y_e}\partial_{y_f}\log K_j(e^y) + \partial_{y_e}\partial_{y_f}\log\Psi_j(e^y)\big)$ at $y = \log\alpha$. By 7.17 the first derivative is $\kappa_{j,\alpha}(e,f)$, and since $\log\Psi_j(e^y) = \langle\mathbf{1},y\rangle + \log K_j(e^{-y})$ (7.2) the second is $\kappa_{j,\alpha^{-1}}(e,f)$. So $\kappa^{\mathbf{E}}_\Upsilon = 4\sum_j \sigma_j\big(C_{j,\alpha} + C_{j,\alpha^{-1}}\big)$, $C_{j,\beta}$ the covariance matrix of the indicators $(X_e)_e$ under $\mathbb{P}_{j,\beta}$, and for $w \in \mathbb{R}^{\mathcal{E}}$

$$w^{\mathsf{T}}\kappa^{\mathbf{E}}_\Upsilon w = 4\sum_j \sigma_j\Big(\operatorname{Var}_{T\sim\mathbb{P}_{j,\alpha}}\langle w,\mathbf{1}_T\rangle + \operatorname{Var}_{T\sim\mathbb{P}_{j,\alpha^{-1}}}\langle w,\mathbf{1}_T\rangle\Big) \;\geq\; 0,$$

since $\sigma_j > 0$ at a realization.

(2) The inequality. The principal 2×2 submatrix of $\kappa^{\mathbf{E}}_{\Upsilon}$ on $\{e, f\}$ is positive semidefinite, so its determinant $\kappa^{\mathbf{E}}_{\Upsilon}(e,e)\kappa^{\mathbf{E}}_{\Upsilon}(f,f) - \kappa^{\mathbf{E}}_{\Upsilon}(e,f)^2$ is nonnegative. It vanishes exactly when that submatrix is singular, that is when some $w = \lambda \mathbf{1}_e + \mu \mathbf{1}_f \neq 0$ has $w^{\mathsf{T}} \kappa^{\mathbf{E}}_{\Upsilon} w = 0$, a positive semidefinite matrix annihilating exactly the vectors at which its form vanishes.

(3) The vectors of form zero. Both laws in step (1) charge every basis (7.16), so $w^{\mathsf{T}} \kappa^{\mathbf{E}}_{\Upsilon} w = 0$ exactly when $\langle w, \mathbf{1}_T \rangle$ is constant over the bases of every table. By 7.8 such a w is constant on every molecule. Conversely, if w is constant on every molecule, with value w_M on the molecule M, then $\langle w, \mathbf{1}_T \rangle = \sum_M w_M r_j(M)$ on every basis of table j, each table being the direct sum of its restrictions to the molecules (7.9).

(4) The cases. If e is a unit, $w = \mathbf{1}_e$ is constant on every molecule, and equality holds; likewise if f is a unit. If neither is a unit and they lie in different molecules, the molecule of e has a mark other than e, not f, at which $w = \lambda \mathbf{1}_e + \mu \mathbf{1}_f$ vanishes, so $\lambda = 0$; likewise $\mu = 0$, and the inequality is strict. If e and f lie in one molecule M: when M has a third mark, w vanishes there, so $\lambda = \mu = 0$ and the inequality is strict; when $M = \{e, f\}$, $w = \mathbf{1}_e + \mathbf{1}_f$ is constant on every molecule, and equality holds. A molecule with at least three marks contains neither a unit nor a molecule of two marks, so the inequality is strict for any two of its marks. □

Remark. The reference, proof of 11.11, has steps (1) to (3) and concludes for a molecule with at least three marks; the case analysis of step (4) gives the equality case for every family.

Lemma 11.12 (Equal diagonals on a class). *As stated: on every class, for both parts and every rung.*

Proof. By 9.4, $\varphi^{\mathbf{X}}_e(v) = \partial_{y_e} \Phi_{\mathbf{X}}(\log \alpha + v \mathbf{1}_e)$, so $(\varphi^{\mathbf{X}}_e)^{(k-1)}(0) = \partial^k_{y_e} \Phi_{\mathbf{X}}(\log \alpha)$, and the still of each part gives

$$\kappa^{\mathbf{X}}_{\Upsilon}(e, \dots, e) = 2^k \, \partial^k_{y_e} \Phi_{\mathbf{X}}(\log \alpha) = 2^k (\varphi^{\mathbf{X}}_e)^{(k-1)}(0).$$

By 10.3(iii) the reading of e determines $\varphi^{\mathbf{E}}_e$ and $\varphi^{\mathbf{O}}_e$; the marks of a class have one reading (10.1), so they have the same self-line functions, and the same derivatives of every order at 0. At an atom there is one class. □

Remark. The reference states 11.12 at an atom of a molecule with at least three marks, for $\kappa^{\mathbf{E}}(e,e)$, and proves it through the rung-two tallies and 11.11. The self-line functions carry every order and both parts, and make the statement one about classes.

Corollary 11.15 (An exchange negates odd cumulants). *As stated, for an exchange of any family.*

Proof. (1) The weight laws. By 11.13, $T \mapsto T' = \mathcal{E} \setminus g(T)$ maps $\mathcal{B}_j$ onto $\mathcal{B}_{h(j)}$ with $\theta_{h(j),T'} = \theta_{j,T}$, and it is injective because g is. So $K_{h(j)}(\mathbf{1}) = K_j(\mathbf{1})$, and for $T \sim \mathbb{P}_{j,\mathbf{1}}$ the basis T' has the law $\mathbb{P}_{h(j),\mathbf{1}}$.

(2) The cumulants. $X_{g(e)}(T') = \mathbf{1}[g(e) \notin g(T)] = 1 - X_e(T)$. Joint cumulants of order at least two are multilinear and unchanged when constants are added to the variables, so for a string $w = (e_1, \dots, e_k)$, $k \geq 2$,

$$\begin{aligned} \kappa_{h(j),\mathbf{1}}(g(w)) &= \kappa\big(X_{g(e_1)}(T'), \dots, X_{g(e_k)}(T')\big) \\ &= \kappa\big(1 - X_{e_1}(T), \dots, 1 - X_{e_k}(T)\big) = (-1)^k \kappa_{j,\mathbf{1}}(w). \end{aligned}$$

(3) The stills. By 9.7, $\kappa_{\Upsilon_{\boldsymbol{\sigma},\boldsymbol{\delta};\mathbf{1}}}(w) = 2^k \sum_j \big(s_j + (-1)^k t_j\big)\kappa_{j,\mathbf{1}}(w)$. The condition on the pairs in 11.13 gives $(s_{h(j)}, t_{h(j)}) = (s_j, t_j)$, and h is a bijection of the tables; reindexing the sum by h and using step (2),

$$\begin{aligned}\kappa_{\Upsilon_{\boldsymbol{\sigma},\boldsymbol{\delta};\mathbf{1}}}(g(w)) &= 2^k \sum_j \big(s_{h(j)} + (-1)^k t_{h(j)}\big)\kappa_{h(j),\mathbf{1}}(g(w)) \\ &= 2^k \sum_j \big(t_j + (-1)^k s_j\big)\kappa_{j,\mathbf{1}}(w),\end{aligned}$$

the still at $\Upsilon_{\boldsymbol{\sigma},-\boldsymbol{\delta};\mathbf{1}}$, whose exponents are (t_j, s_j).

(4) The classes of the centre. By 11.14 with $F' = F$ at the table's gauge, the reading of $g(e)$ at $-\boldsymbol{\delta}$ equals that of e at $\boldsymbol{\delta}$; at the centre $-\boldsymbol{\delta} = \boldsymbol{\delta} = 0$, so $g(e)$ lies in the class of e. Hence g maps every class of the centre into itself, and onto itself, g being injective and the class finite. □

Remark. The reference, proof of 11.15, is the case of one table, where h is the identity.

50.12 Chapter 12: restriction to a bunch

Lemma 12.3 (Children do not widen). *As stated.*

Proof. The child at p is a table on R (12.2), and a set $X \subseteq R$ is one of its bases exactly when $p \sqcup X$ is a basis of the table. Since $p, W \subseteq B$ and $X, A \subseteq R$,

$$|X \cap A| = |(p \sqcup X) \cap (A \cup W)| - |p \cap W|.$$

So the traces of A on the bases of the child are traces of $A \cup W$ on bases of the table, all shifted by the one constant $|p \cap W|$. The width is the largest trace less the least (7.13), so $c_{(p)}(A) \le c(A \cup W)$. □

Proposition 12.13 (Coins of a tensorminental table). *As stated: tensor rank one over* $\mathbb{R}$ *or over* $\mathbb{C}$.

Proof. The first display is proved in the reference, proof of 12.13. At tensor rank one there is one slice $A \in \mathbb{F}^{r\times n}$, of rank r since $K(\mathbf{1}) = \det(AA^{\mathsf{H}}) > 0$ (7.21); the only pair is $(1,1)$, with $w_{11} = 1$, and $\Pi^{(11)} = A^{\mathsf{H}} M^{-1} A D_\alpha$, $M = A D_\alpha A^{\mathsf{H}}$ (7.23). So $x^{d(B)} \mathsf{Q}_B^K(x;\alpha) = \prod_{i=1}^{|B|}(1 - p_i + p_i x)$ with p_i the eigenvalues of $\Pi^{(11)}_{BB}$.

(1) The projection. Put $P = D_\alpha^{1/2} \Pi^{(11)} D_\alpha^{-1/2} = D_\alpha^{1/2} A^{\mathsf{H}} M^{-1} A D_\alpha^{1/2}$. Then $P^{\mathsf{H}} = P$ and $P^2 = D_\alpha^{1/2} A^{\mathsf{H}} M^{-1} (A D_\alpha A^{\mathsf{H}}) M^{-1} A D_\alpha^{1/2} = P$, and $P\, D_\alpha^{1/2} A^{\mathsf{H}} = D_\alpha^{1/2} A^{\mathsf{H}}$; so P is the orthogonal projection onto $\{D_\alpha^{1/2} A^{\mathsf{H}} y\}$, the row space of $A D_\alpha^{1/2}$ in the sense of 7.23.

(2) Similarity. D_α is diagonal, so $P_{BB} = D_B^{1/2} \Pi^{(11)}_{BB} D_B^{-1/2}$, with D_B the diagonal block on B, and P_{BB} has the eigenvalues p_i.

(3) Principal angles. P_{BB} is the compression of P to $\mathbb{F}^B$, the vectors supported on B: $v^{\mathsf{H}} P_{BB} v = \|Pv\|^2$ for $v \in \mathbb{F}^B$. With E_B the inclusion of $\mathbb{F}^B$ and Q a matrix whose columns are an orthonormal basis of the range of P, $P_{BB} = (E_B^{\mathsf{H}} Q)(E_B^{\mathsf{H}} Q)^{\mathsf{H}}$. Its eigenvalues are the squares of the singular values of $E_B^{\mathsf{H}} Q$, completed by zeros, which are the cosines of the principal angles between $\mathbb{F}^B$ and the range of P; they lie in $[0,1]$.

(4) The eigenvalue 1. For $v \in \mathbb{F}^B$, $P_{BB} v = v$ exactly when $\|Pv\| = \|v\|$, that is when v lies in the range of P. So the eigenspace is $\{D_\alpha^{1/2} A^{\mathsf{H}} y :\ (D_\alpha^{1/2} A^{\mathsf{H}} y)_R = 0\} = \{D_\alpha^{1/2} A^{\mathsf{H}} y :\ A_R^{\mathsf{H}} y = 0\}$, of dimension $r - \operatorname{rank} A_R$, the map $y \mapsto D_\alpha^{1/2} A^{\mathsf{H}} y$ being injective. The bases of the table are the

sets T with $\det A_T \neq 0$ (7.20), so $r(R) = \operatorname{rank} A_R$, and $r - r(R) = d(B)$ (7.12, $d(B) = |B| - r^*(B)$ with $r^*(B) = |B| + r(R) - r$).

(5) The eigenvalue 0. For $v \in \mathbb{F}^B$, $P_{BB}v = 0$ exactly when $Pv = 0$, that is $AD_\alpha^{1/2}v = A_B D_B^{1/2} v_B = 0$. So the eigenspace has dimension $|B| - \operatorname{rank} A_B = |B| - r(B) = d^*(B)$.

(6) The coins. P_{BB} is Hermitian, so of its $|B|$ eigenvalues $d(B)$ are 1, $d^*(B)$ are 0, and the other $|B| - d(B) - d^*(B) = c(B)$ lie in $(0,1)$. In $x^{d(B)}\mathsf{Q}_B^K(x;\alpha) = \prod_i (1 - p_i + p_i x)$ the eigenvalues 1 give the factor $x^{d(B)}$ and the eigenvalues 0 the factor 1; so the coins of Q_B^K are the eigenvalues $p_i = \cos^2 \vartheta_i \in (0,1)$, and the Skeleton values are $\xi_i = (1 - p_i)/p_i = \tan^2 \vartheta_i > 0$ (12.10). □

Remark. Over $\mathbb{R}$ this is the reference, proof of 12.13. Over $\mathbb{C}$ the projection is Hermitian, and each step reads the same with conjugate transposes.

Definition 12.18: the claims. $\operatorname{pat}(B) = 2^B$ holds exactly when B is independent (B is a pattern) and some basis avoids B ($\varnothing$ is a pattern): if both hold, $d(B) = 0$, so the contraction $\mathcal{B}/R$ has rank 0, and every subset of B is independent with $r_{\mathcal{B}/R} = 0 = d(B)$, a pattern by Proposition 12.17(i). Equivalently $r(B) = |B|$ and $d(B) = 0$, that is $c(B) = |B|$. The dual table has the bases $\mathcal{E} \setminus T$ and the patterns $B \setminus p$, with the children of cobasis letters $\Psi_{(p)}$; so every subset of B is a pattern of the dual table when every subset is a pattern of the table, and its interaction is $\sum_p (-1)^{|B \setminus (B \setminus p)|} \log \Psi_{(p)} = \iota_B^*$. The parts: $\Phi_{\mathbf{E}} = \sum_j \sigma_j (\log K_j + \log \Psi_j)$ and $\Phi_{\mathbf{O}} = \sum_j \delta_j (\log K_j - \log \Psi_j)$ (Definition 8.18), and $\sigma_j \pm \delta_j$ are s_j and t_j.

Proposition 12.20 (The bottom of a chain factors over its steps). *As stated.*

Proof. Existence. Order the marks of each step arbitrarily and the steps as they come; the sets S_i are initial segments of this order of $\mathcal{E}$, which are the tails of the reversed order, and 8.3 gives a basis T^+ with $|T^+ \cap U| = d(U)$ for every tail U, in particular at the bottom of every S_i.

One step is exchanged at a time. Let T and T' be at the bottom of every S_k, and $1 \le i \le \ell + 1$. For $i \ge 2$, by 12.19 at the bunch S_{i-1} the bases at its bottom are all the unions of a pattern of that level and a room side of that level, so $T'' = (T' \cap S_{i-1}) \cup (T \setminus S_{i-1})$ is a basis; for $i = 1$ put $T'' = T$. Its traces are $|T'' \cap S_k| = |T' \cap S_k| = d(S_k)$ for $k < i$ and $d(S_{i-1}) + |T \cap S_k| - |T \cap S_{i-1}| = d(S_k)$ for $k \ge i$. For $i \le \ell$, 12.19 at the bunch S_i, applied to T'' and T', both at its bottom, gives the basis $(T'' \cap S_i) \cup (T' \setminus S_i) = (T' \setminus Z_i) \cup (T \cap Z_i)$; for $i = \ell + 1$ this set is T'' itself. Its trace on S_k is that of T' for $k < i$, and for $k \ge i$ it is

$$d(S_{i-1}) + \big(d(S_i) - d(S_{i-1})\big) + \big(d(S_k) - d(S_i)\big) = d(S_k),$$

since T and T' meet Z_i in $d(S_i) - d(S_{i-1})$ marks and $S_k \setminus S_i$ in $d(S_k) - d(S_i)$. So the part on one step of a basis at the bottom of every S_k can be replaced by that of any other, and these bases are exactly the unions of their traces on the steps, chosen independently.

The step tables. If $(T_0 \setminus Z_i) \sqcup X$ is a basis with $X \subseteq Z_i$, then $|X| = |T_0 \cap Z_i|$, its traces on the S_k are those of T_0, and it is at the bottom of every S_k. Conversely, for T at the bottom of every S_k the exchange gives the basis $(T_0 \setminus Z_i) \cup (T \cap Z_i)$. So the traces on Z_i are the bases of the child at the pattern $T_0 \setminus Z_i$, a table (12.2), the same set for every T_0. A basis T at the bottom of S_{i-1} and of S_i alone has the same trace on Z_i as one at the bottom of every S_k: the two exchanges above with $T' = T_0$ use only that T is at the bottom of S_{i-1} and of S_i, and give the basis $(T_0 \setminus Z_i) \cup (T \cap Z_i)$, whose traces were computed above. So the step table depends on S_{i-1} and S_i alone.

The top. $|T \cap S_i|$ is largest exactly when the cobasis $\mathcal{E} \setminus T$ meets S_i least, so the bases at the top of every S_i are the complements of the bases at the bottom of every S_i in the dual table (7.1), and the above applies there. For q a pattern of $\mathcal{E} \setminus Z_i$ in the dual table, $X \subseteq Z_i$ is a basis of its

child exactly when $\big((\mathcal{E}\setminus Z_i)\setminus q\big)\sqcup(Z_i\setminus X)$ is a basis of $\mathcal{B}$: the child of the dual table at q is the dual of the child of $\mathcal{B}$ at $(\mathcal{E}\setminus Z_i)\setminus q$. At $q=(\mathcal{E}\setminus T_1)\setminus Z_i$ this is the dual of $\mathcal{B}_{(T_1\setminus Z_i)}$.

The letters. The degree of α^T in α_{S_i} is $|T\cap S_i|$, whose least value is $d(S_i)$, attained for every i at once by the bases at the bottom of every S_i; for a list their sum is $\sum_{X_1,\dots,X_{\ell+1}}\prod_i \alpha^{X_i}=\prod_i K_{\mathcal{B}_{(T_0\setminus Z_i)}}(\alpha_{Z_i})$, and with weights $\theta_T=\prod_i\theta_i(T\cap Z_i)$ the same with the weights θ_i. The degree of $\alpha^{\mathcal{E}\setminus T}$ in α_{S_i} is $|S_i\setminus T|$, least exactly when T is at the top of S_i, and by the dual statement the terms of Ψ of the least degree for every i at once are $\prod_i K_{(\mathcal{B}_{(T_1\setminus Z_i)})^*}(\alpha_{Z_i})=\prod_i\Psi_{\mathcal{B}_{(T_1\setminus Z_i)}}(\alpha_{Z_i})$ (7.2). The bases of $\binom{J}{1}$ on $\mathcal{E}$ are the $\{j\}$, $j\in J$, and $d(S)$ is 1 or 0 as $J\subseteq S$ or not; so $\{j\}$ is at the bottom of every S_k exactly when $j\notin S_k$ for every k with $J\not\subseteq S_k$, that is when $j\in J\cap Z_{i_0}$, Z_{i_0} the first step with $J\subseteq S_{i_0}$. Its step table at Z_{i_0} has the bases $\{j\}$, $j\in J\cap Z_{i_0}$, and its step tables at the other steps the one basis $\varnothing$.

A maximal chain. When every step is one mark, a basis at the bottom of every S_i meets the step $\{e_i\}$ in $d(S_i)-d(S_{i-1})$ marks, so it is determined by the chain, and it exists; its term in K is one monomial, with the coefficient 1 for a list. □

Corollary 12.23 (The native level split is interior). *As stated: the directions come from chains of circuits joining the marks of each side, which a connected table with a positive exponent supplies.*

Proof. The first two sentences, the relative interior and the walls with their exceptions, are proved in the reference, proof of 12.23, without any connectedness. Write $\mathcal{L}$ for the set of level and colevel letters with positive exponent, $c_L>0$ for the exponent of $L\in\mathcal{L}$, N_L for the convex hull of its exponent vectors, and $Q=\sum_{L\in\mathcal{L}}c_LN_L$ for the Minkowski sum of the statement.

(1) A circuit with two marks on one side. Let $a\neq a'$ lie both in B or both in R, and in a common circuit of a table j with a positive exponent. By 7.7 some basis T of table j has $a\in T$, $a'\notin T$ and $T'=(T\setminus\{a\})\cup\{a'\}$ a basis, and $|T\cap B|=|T'\cap B|=:k$, the two marks lying on one side. At the native gauge every basis has positive probability under both laws (7.16). If $s_j>0$, the level letter $K^{(k)}_{j,B}$ has the positive exponent $s_j\mathbb{P}_{j,\alpha^\star}(N_B=k)$, and $N_{K^{(k)}_{j,B}}$ contains $\mathbf{1}_T$ and $\mathbf{1}_{T'}$, whose difference is $\mathbf{1}_a-\mathbf{1}_{a'}$. If $t_j>0$, the colevel letter $\Psi^{(|B|-k)}_{j,B}$ has the positive exponent $t_j\mathbb{P}^*_{j,\alpha^\star}(N^*_B=|B|-k)$, and its polytope contains $\mathbf{1}_{\mathcal{E}\setminus T}$ and $\mathbf{1}_{\mathcal{E}\setminus T'}$, whose difference is $\mathbf{1}_{a'}-\mathbf{1}_a$. Fixing points of the other summands, $c_L(\mathbf{1}_a-\mathbf{1}_{a'})$ is the difference of two points of Q for one $L\in\mathcal{L}$, so every v with $\langle v,x\rangle$ constant on Q has $v_a=v_{a'}$.

(2) The directions. Under the hypothesis the chains join all the marks of B and all the marks of R, so by step (1) such a v is constant on B and on R. Conversely, a monomial α^T of a level letter of level k has $\langle\mathbf{1}_B,\mathbf{1}_T\rangle=k$, and a monomial $\alpha^{\mathcal{E}\setminus T}$ of a colevel letter of colevel k has $\langle\mathbf{1}_B,\mathbf{1}_{\mathcal{E}\setminus T}\rangle=|B\setminus T|=k$; so $\langle\mathbf{1}_B,x\rangle$ is constant on every N_L, hence on Q, and so is $\langle\mathbf{1}_R,x\rangle=\langle\mathbf{1},x\rangle-\langle\mathbf{1}_B,x\rangle$, each letter being homogeneous. So the directions v with $\langle v,x\rangle$ constant on Q are $\operatorname{span}\{\mathbf{1}_B,\mathbf{1}_R\}$.

(3) The exceptions. A linear function is constant on a Minkowski sum with positive coefficients exactly when it is constant on every summand. So S is an exception exactly when $\mathbf{1}_S\in\operatorname{span}\{\mathbf{1}_B,\mathbf{1}_R\}$, that is $S\in\{\varnothing,B,R,\mathcal{E}\}$.

(4) Convergence. Write $\alpha_B=\rho_Bu$ with $\rho_B=\langle\mathbf{1}_B,\alpha_B\rangle$ and $\alpha_B=e^{y_B}$; then $d\alpha_B=\rho_B^{|B|-1}d\rho_B\,d\omega_B(u)=\prod_{e\in B}\alpha_e\,dy_B$, and splitting y_B into its component t along the unit vector $|B|^{-1/2}\mathbf{1}_B$, which changes ρ_B by the factor $e^{t|B|^{-1/2}}$ and leaves u unchanged, and its component orthogonal to $\mathbf{1}_B$, on which u depends, gives $d\rho_B/\rho_B=|B|^{-1/2}dt$ and so $d\omega_B(u)=|B|^{1/2}\prod_{e\in B}u_e\,dy_B$ on the hyperplane $\langle y_B,\mathbf{1}_B\rangle=0$; likewise on R. So with $Y=\{y:\ \langle y_B,\mathbf{1}_B\rangle=$

$\langle y_R, \mathbf{1}_R\rangle = 0\}$ the integral of the statement is $(|B||R|)^{1/2}\int_Y u^{\boldsymbol\tau|_B} v^{\boldsymbol\tau|_R}\prod_{L\in\mathcal{L}} L(u,v)^{-c_L}dy$, with $u = e^{y_B}/\rho_B$ and $v = e^{y_R}/\rho_R$. Each L is homogeneous in α_B and in α_R, and the degrees weighted by the exponents add to τ_B and to τ_R: for the level letters of table j they add to $s_j\mathbb{E}_{T\sim\mathbb{P}_{j,\alpha^\star}}[N_B] = s_j\sum_{e\in B} R_{j,e}(\alpha^\star)$ in α_B, for its colevel letters to $t_j\mathbb{E}_{T\sim\mathbb{P}^*_{j,\alpha^\star}}[N^*_B] = t_j\sum_{e\in B} R^*_{j,e}(\alpha^\star)$, and the usage at the native gauge is $\boldsymbol\tau$ (8.17); likewise on R. So the powers of ρ_B and ρ_R cancel, and the integrand is $e^{\langle\boldsymbol\tau,y\rangle}\prod_L L(e^y)^{-c_L}$. Each $L(e^y)$ is at least its least coefficient times $e^{\max_{x\in N_L}\langle x,y\rangle}$, the maximum being attained at an exponent vector; so the integrand is at most $C\exp\big(-(h(y)-\langle\boldsymbol\tau,y\rangle)\big)$, with $h(y)=\max_{x\in Q}\langle x,y\rangle = \sum_L c_L\max_{x\in N_L}\langle x,y\rangle$. By step (2) the affine hull of Q has the direction space $\operatorname{span}\{\mathbf{1}_B,\mathbf{1}_R\}^\perp = Y$, and $\boldsymbol\tau$ lies in the relative interior of Q; so for some $\varepsilon>0$, $\boldsymbol\tau + w\in Q$ for all $w\in Y$ with $\|w\|\le\varepsilon$, and $h(y)\ge\langle\boldsymbol\tau,y\rangle+\varepsilon\|y\|$ for $y\in Y$. The integrand is at most $Ce^{-\varepsilon\|y\|}$, integrable over Y.

(5) A connected table. In a connected table any two marks lie in a common circuit, the fact used in the reference, proof of 12.23; so a connected table with a positive exponent joins any two marks of B, and any two marks of R, by a chain of length one. □

Remark. The hypothesis cannot be replaced by connectedness of the family. On $\mathcal{E}=\{a,a',b,b'\}$ with $B=\{a,a'\}$, let the three tables of rank one with the bases $\{a\},\{b\}$, then $\{a'\},\{b'\}$, then $\{a\},\{b'\}$ carry positive exponents, read at a native gauge. The family is connected, but every level of every table holds one basis, so every level and colevel polytope is a point, every set is an exception, and the wall at $\{a\}$ vanishes. Each circuit $\{a,b\}$, $\{a',b'\}$, $\{a,b'\}$ meets both sides, and no chain on one side joins a to a'.

50.13 Chapter 13: the order of classes and the Foreman bunch

Proposition 13.10 (Mirror classes). *As stated: levels mirrored up to a bijection of the tables, and the exchange of any family.*

Proof. (i) Fix j. Under $\mathbb{P}_{h(j),\mathbf{1}}$ the level N_D takes the value a with probability $\mathbb{P}_{j,\mathbf{1}}(N_C = k_j - a)$, so it has the law of $k_j - N_C$ under $\mathbb{P}_{j,\mathbf{1}}$. A cumulant of order $a\ge 2$ is unchanged by adding a constant and is homogeneous of degree a, so $\kappa_{h(j),\mathbf{1}}(N_D^{\times a}) = (-1)^a\kappa_{j,\mathbf{1}}(N_C^{\times a})$. Since h is a bijection of the tables with $\sigma_{h(j)}=\sigma_j$,

$$\sum_j \sigma_j\kappa_{j,\mathbf{1}}(N_D^{\times a}) = \sum_j \sigma_{h(j)}\kappa_{h(j),\mathbf{1}}(N_D^{\times a}) = (-1)^a\sum_j \sigma_j\kappa_{j,\mathbf{1}}(N_C^{\times a}),$$

and likewise with the δ_j. By 13.4(i) the coefficients of v_0^a, $a\ge 2$, in the **E** part of stage 0 are $\frac{2}{a!}\sum_j\sigma_j\kappa_{j,\mathbf{1}}(N_C^{\times a})$ at even a and zero at odd a, and in its **O** part $\frac{2}{a!}\sum_j\delta_j\kappa_{j,\mathbf{1}}(N_C^{\times a})$ at odd a and zero at even a; so the **E** parts of $\mathcal{V}_0(C)$ and $\mathcal{V}_0(D)$ are equal and their **O** parts are negatives.

(ii) Stage 0 holds one pair. By (i) the **E** parts agree, so the pairs are compared by their **O** parts (13.5(iii)). Their coefficients vanish at every even a and at every odd a below the least odd a with $c=\frac{2}{a!}\sum_j\delta_j\kappa_{j,\mathbf{1}}(N_C^{\times a})\neq 0$, where C has c and D has $-c$. So stage 0 separates C and D, and $C\prec D$ exactly when $c<-c$, that is $c<0$. At the opposite lean c changes sign, being linear in $\boldsymbol\delta$, and the order is the other one.

(iii) At the centre the **O** parts vanish and the **E** parts agree by (i), so stage 0 does not separate C and D. They are different classes with equally many marks and $\prec$ is a strict total order on them (13.7(i)), so a later stage does.

The two instances. If C and D together make up the molecule, $|T\cap D| = r_j - |T\cap C|$ on every basis of table j: h is the identity and $k_j = r_j$. If g exchanges the family, with h the bijection of its

tables, then for $T \sim \mathbb{P}_{j,\mathbf{1}}$ the basis $T' = \mathcal{E} \setminus g(T)$ has the law $\mathbb{P}_{h(j),\mathbf{1}}$ (proof of 11.15, step (1)) and $|T' \cap g(C)| = |g(C) \setminus g(T)| = |C \setminus T| = |C| - |T \cap C|$, so $\mathbb{P}_{h(j),\mathbf{1}}(|T \cap g(C)| = a) = \mathbb{P}_{j,\mathbf{1}}(|T \cap C| = |C| - a)$ and $k_j = |C|$. Moreover $g(C)$ is a class at the lean with $|C|$ marks: g maps the classes at $\boldsymbol{\delta}$ onto those at $-\boldsymbol{\delta}$ (11.14), which are the classes at $\boldsymbol{\delta}$ (11.2). □

Remark. The reference, proof of 13.10, takes the mirror table by table, h the identity, and the exchange of a one-table molecule. Its conclusions use only the sums over the tables weighted by the σ_j and the δ_j, which a bijection of the tables preserving the pairs leaves unchanged.

50.14 Chapter 14: peel, children and the Foreman tree

Corollary 14.9 (A molecule with an exchange). *As stated: a molecule with any number of tables; the classes of the centre are those of 11.15.*

Proof. Read M as the family $F|M$ of the restrictions of the tables to M (14.1), with the pair coordinates (σ_j, δ_j) of its tables. By 11.13 an exchange g of M comes with a bijection h of the tables such that $T \mapsto M \setminus g(T)$ maps the bases of table j onto those of table $h(j)$, with their weights, and $(\sigma_{h(j)}, \delta_{h(j)}) = (\sigma_j, \delta_j)$. The first two conditions concern the tables alone, and the third holds with $\boldsymbol{\delta}$ replaced by $-\boldsymbol{\delta}$ or by 0 when it holds at $\boldsymbol{\delta}$. So g exchanges M at each of the leans $\boldsymbol{\delta}$, $-\boldsymbol{\delta}$ and 0; likewise a bijection carrying M at $\boldsymbol{\delta}$ carries it at these three leans.

Trees and bunches. 14.8 with $F = F' = M$ gives $g\big(\operatorname{Tree}(M;\boldsymbol{\sigma},\boldsymbol{\delta})\big) = \operatorname{Tree}(M;\boldsymbol{\sigma},-\boldsymbol{\delta})$, each recorded bunch going onto the bunch recorded at the same place. At the root the recorded bunches are $B(M;\boldsymbol{\sigma},\boldsymbol{\delta})$ and $B(M;\boldsymbol{\sigma},-\boldsymbol{\delta})$ (14.4), so $g\big(B(M;\boldsymbol{\sigma},\boldsymbol{\delta})\big) = B(M;\boldsymbol{\sigma},-\boldsymbol{\delta})$. At the lean 0 the two trees are one tree, which gives $g\big(\operatorname{Tree}(M;\boldsymbol{\sigma},0)\big) = \operatorname{Tree}(M;\boldsymbol{\sigma},0)$ and $g\big(B(M;\boldsymbol{\sigma},0)\big) = B(M;\boldsymbol{\sigma},0)$.

Classes of the centre. 11.15, applied to the family $F|M$.

A carrying map. Let g carry M. 11.14 at the tables' gauges, where $g^* \log \mathbf{1} = \log \mathbf{1}$, says that the reading of $g(e)$ equals that of e at $\Upsilon_{\boldsymbol{\sigma},\boldsymbol{\delta};\mathbf{1}}$, for every mark e. So $g(e)$ lies in the class of e, that is $g(C) \subseteq C$ for every class C, and $g(C) = C$ since g is injective and C is finite. The last sentence of 14.8, at each of the three leans at which g carries M, maps each of the trees at 0, $\boldsymbol{\delta}$ and $-\boldsymbol{\delta}$ onto itself. □

Lemma 14.10 (An exchange turns a window over). *As stated: an exchange of one family with another, table by table through the bijection h of the tables.*

Proof. Let F be on $\mathcal{E}$ and F' on $\mathcal{E}'$. By 11.13 the map $T \mapsto \mathcal{E}' \setminus g(T)$ is a bijection from the bases of table j of F onto those of table $h(j)$ of F'. For a basis T, g being a bijection,

$$\big|(\mathcal{E}' \setminus g(T)) \cap g(S)\big| = |g(S)| - |g(T) \cap g(S)| = |S| - |T \cap S|.$$

By 7.13 the numbers $|T \cap S|$, T a basis of table j, fill $\{d_j(S), \dots, r_j(S)\}$. So the numbers $|T' \cap S'|$, T' a basis of table $h(j)$, fill $\{|S| - r_j(S), \dots, |S| - d_j(S)\}$, a window of the same width $c_j(S) = r_j(S) - d_j(S)$, and the bijection takes the bases of table j at level k on S to those of table $h(j)$ at level $|S| - k$ on S'. This is the reference, proof of 14.10, with h. □

Proposition 14.12 (Level form). *As stated: table by table in a family, and for the family through the bijections that carry it with the identity on its tables.*

Proof. Fix a table j and a transposition τ of two marks of B fixing every other mark. A basis T with $T \cap B = p$ is $p \sqcup X$ with X a basis of the child at p, of weight $\theta_{j,(p),X} = \theta_{j,T}$, and

$K_{j,(p)}(\alpha_R) = \sum_X \theta_{j,(p),X}\alpha_R^X$ (12.1, 12.7). Distinct bases of one child give distinct monomials, so $K_{j,(p)}$ determines the child at p with its weights, and $K_{j,(p)} = 0$ when p is not a pattern.

Let $K_{j,(p)} = K_{j,(p')}$ whenever $|p| = |p'|$. For a basis $T = p \sqcup X$, $\tau(T) = \tau(p) \sqcup X$, since τ fixes R, and $|\tau(p)| = |p|$. So X is a basis of the child at $\tau(p)$ with the weight $\theta_{j,(p),X}$: $\tau(T)$ is a basis of table j and $\theta_{j,\tau(T)} = \theta_{j,T}$. Hence τ maps the bases of table j into themselves with their weights, and onto them, being injective on a finite set.

Conversely, let every such transposition map the bases of table j onto themselves with their weights, and let $p, p' \subseteq B$ have $|p| = |p'|$. The transpositions of marks of B generate the permutations of B, so a product ς of them has $\varsigma(p) = p'$; it maps the bases onto themselves with their weights and fixes R. So $p \sqcup X \mapsto p' \sqcup X$ is a bijection from the bases with trace p onto those with trace p' keeping the weights, and $K_{j,(p')} = K_{j,(p)}$. This is the reference, proof of 14.12, for table j, where 14.7(i) is used with the identity on R.

B is in level form in the family when it is in level form in every table, that is, by the above, when every such transposition maps the bases of every table onto themselves with their weights. That is the condition of 11.13 with $F' = F$ and h the identity, whose condition on the pairs, $(\sigma_{h(j)}, \delta_{h(j)}) = (\sigma_j, \delta_j)$, then holds by itself. □

Definition 14.17 (Keeping the potential; twins; descents; copies). As stated: keeping and taking the potential at every realization; twins, descents and copies at the table's gauge.

Lemma 14.18 (The writings certify the potential). *As stated, at every realization* $\Upsilon = ((s_j, t_j)_j; \alpha)$.

Proof. Let M have n marks, and let $(\Phi_{\mathbf{E}}, \Phi_{\mathbf{O}})$ be its potential. For a mark x and an order $w = (w_1, \dots, w_{n-1})$ of its room, the potential written from x in the order w is the pair of functions

$$\Phi^{\mathbf{X}}_{x,w}(v_0, \dots, v_{n-1}) = \Phi_{\mathbf{X}}\Big(\log\alpha + v_0\mathbf{1}_x + \sum_{i=1}^{n-1} v_i\mathbf{1}_{w_i}\Big)$$

(10.1). For a bijection g and a mark a, $g^*\mathbf{1}_{g(a)} = \mathbf{1}_a$, since $(g^*\mathbf{1}_{g(a)})_e = (\mathbf{1}_{g(a)})_{g(e)} = \mathbf{1}[e = a]$.

(i) By 10.4 there are orders $(a_1, \dots, a_{n-1})$ of the room of e and $(b_1, \dots, b_{n-1})$ of the room of f with $\Phi^{\mathbf{X}}_{e,(a_i)_i} = \Phi^{\mathbf{X}}_{f,(b_i)_i}$ for both parts. Put $a_0 = e$ and $b_0 = f$, and let β be the bijection with $\beta(a_i) = b_i$ for $0 \le i \le n-1$; so $\beta(e) = f$. For $y \in \mathbb{R}^M$ put $v_i = y_{b_i}$. Then $\sum_i v_i\mathbf{1}_{b_i} = y$ and $\sum_i v_i\mathbf{1}_{a_i} = \sum_i y_{\beta(a_i)}\mathbf{1}_{a_i} = \beta^* y$, and the equality of the two writings at $(v_0, \dots, v_{n-1})$ reads

$$\Phi_{\mathbf{X}}(\log\alpha + \beta^* y) = \Phi_{\mathbf{X}}(\log\alpha + y)$$

for every y and both parts: β keeps the potential (14.17).

(ii) Let g keep the potential. For a mark x, an order w of its room and $v \in \mathbb{R}^n$, put $y = v_0\mathbf{1}_{g(x)} + \sum_i v_i\mathbf{1}_{g(w_i)}$; then $g^* y = v_0\mathbf{1}_x + \sum_i v_i\mathbf{1}_{w_i}$, and

$$\Phi^{\mathbf{X}}_{x,w}(v) = \Phi_{\mathbf{X}}(\log\alpha + g^* y) = \Phi_{\mathbf{X}}(\log\alpha + y) = \Phi^{\mathbf{X}}_{g(x),g(w)}(v), \qquad g(w) = (g(w_1), \dots, g(w_{n-1})).$$

As w runs over the orders of the room of x, $g(w)$ runs over those of the room of $g(x)$, once each. So the readings of x and of $g(x)$, the multisets of these pairs of functions, are equal, and $g(x)$ lies in the class of x. Thus $g(C) \subseteq C$ for every class C, and $g(C) = C$, g being injective and C finite.

Let $g : M \to M'$ take the potential of M, read at Υ, to that of M', read at a realization with the gauge α'. The same computation gives $\Phi^{\mathbf{X}}_{x,w}(v) = \Phi'^{\mathbf{X}}_{g(x),g(w)}(v) + c_{\mathbf{X}}$: the reading of x in M is the reading of $g(x)$ in M' with every function shifted by the constants $c_{\mathbf{X}}$. So two marks of M

have equal readings exactly when their images have equal readings in M', and g maps the classes of M onto those of M'.

The centre of $\Upsilon = \Upsilon_{\boldsymbol{\sigma},\boldsymbol{\delta};\alpha}$ is $\Upsilon_{\boldsymbol{\sigma},0;\alpha}$, read at the same gauge (10.1). Its potential is $(\Phi_{\mathbf{E}}, 0)$, $\Phi_{\mathbf{E}} = \sum_j \sigma_j \log \mathbf{E}_j(e^y)$ being the same function at every lean (8.18). A bijection keeping the potential at Υ keeps it at the centre, and one taking the potential of M to that of M' at their realizations takes it at their centres, with the constants $(c_{\mathbf{E}}, 0)$; so the two preceding paragraphs hold at the centre as well.

For the last sentence: if e and f read alike, (i) gives a bijection keeping the potential that takes e to f; conversely, a bijection keeping the potential maps the class of e onto itself by (ii), so if it takes e to f, then f lies in that class. □

Remark. At the table's gauge $\log \alpha = 0$, the two conditions of 14.17 read $\Phi_{\mathbf{X}} \circ g^* = \Phi_{\mathbf{X}}$ and $\Phi_{\mathbf{X}} \circ g^* = \Phi'_{\mathbf{X}} + c_{\mathbf{X}}$, and the proof above is the reference, proof of 14.18. The statements that keep or take the potential at the table's gauge, 14.20, 14.21, 14.22, 29.9 and 29.11, and the twins, descents and copies of 14.17, read these conditions as in the reference.

50.15 Chapter 15: the integral at a bunch

Proposition 15.2 (Where the Breta of one bunch converges). *As stated.*

Proof. The set. If a convex combination of the coordinates of $t\boldsymbol{\xi} + (1-t)\mathbf{1}$, $0 < t \leq 1$, were a point $p \in (-\infty, 0]$, the same combination of the ξ_ℓ would be $(p-1+t)/t \in (-\infty, 0]$; at $t = 0$ the combination is 1. So Ξ_J is star-shaped about $\mathbf{1}$, hence connected. The convex hull of the ξ_ℓ is compact and avoids the closed set $(-\infty, 0]$, so it lies at a distance $\delta > 0$ from it, and moving every ξ_ℓ by less than δ moves every convex combination by less than δ: Ξ_J is open. Convex combinations of points with positive real parts have positive real parts.

The integral. Put $\nu = |\mathbf{w}| - \kappa$, so $\operatorname{Re}\nu > 0$, and $z(u) = \sum_\ell \xi_\ell u_\ell$, which for u in the closed simplex lies in the convex hull of the ξ_ℓ. On a compact neighbourhood of a point of Ξ_J inside Ξ_J these hulls stay at a distance at least some $\delta' > 0$ from $(-\infty, 0]$, so the principal branch $z^{-\nu} = \exp(-\nu \log z)$ is holomorphic in $\boldsymbol{\xi}$ and $|z^{-\nu}| = |z|^{-\operatorname{Re}\nu} e^{\operatorname{Im}\nu \arg z} \leq \delta'^{-\operatorname{Re}\nu} e^{\pi|\operatorname{Im}\nu|}$ there. Since $u^{\mathbf{w}-\mathbf{1}}$ is integrable on Δ_J for $\operatorname{Re} w_\ell > 0$ (3.9), the integral converges absolutely, locally uniformly, and is holomorphic in $\boldsymbol{\xi}$ on Ξ_J. At positive coefficients it is the Breta: with the unit configuration on one bunch the Zamma is $\Gamma(\nu)^{-1} \int_0^\infty x^{\nu-1} e^{-x\sum_\ell \xi_\ell u_\ell} dx = z(u)^{-\nu}$ (2.1, 2.12).

The identity. The left side of 15.1 is holomorphic on $(\mathbb{C} \setminus (-\infty, 0])^J \supseteq \Xi_J$, and the stacked Gamma does not depend on $\boldsymbol{\xi}$; the two sides agree on $(0, \infty)^J$. A holomorphic function on the connected open set Ξ_J that vanishes on the nonempty open set $(0, \infty)^J$ of its real points vanishes identically, its Taylor coefficients at a real point being its real derivatives there; so they agree on Ξ_J. □

Corollary 15.4 (The scale of a bunch of width one). *As stated: every bunch, table by table, with one Skeleton value in each table of width one.*

Proof. Fix a table j and write $d = d_j(B)$, $d^* = d_j^*(B)$ and $c = c_j(B)$. By 7.13 the levels $|T \cap B|$ fill $\{d, \ldots, d+c\}$, and the colevels $|B \setminus T|$ fill $\{|B| - d - c, \ldots, |B| - d\} = \{d^*, \ldots, d^* + c\}$, since $d^* = |B| - r_j(B) = |B| - d - c$ (7.12). Each level letter $K_{j,B}^{(k)}$ and each colevel letter $\Psi_{j,B}^{(k)}$ in these windows is a sum of positive terms over a nonempty set of bases, positive on the orthant. By

12.16,

$$x^d \mathsf{Q}^K_{j,B}(x;\alpha) = \sum_{k=d}^{d+c} x^k \frac{K^{(k)}_{j,B}(\alpha)}{K_j(\alpha)}, \qquad x^{d^*} \mathsf{Q}^\Psi_{j,B}(x;\alpha) = \sum_{k=d^*}^{d^*+c} x^k \frac{\Psi^{(k)}_{j,B}(\alpha)}{\Psi_j(\alpha)}.$$

If $c = 0$ both Skeleton polynomials are the constant 1, of degree 0, and the spectra are empty (12.10). If $c = 1$, then $K_j = K^{(d)}_{j,B} + K^{(d+1)}_{j,B}$, and with $\xi = K^{(d)}_{j,B}(\alpha)/K^{(d+1)}_{j,B}(\alpha) > 0$,

$$\mathsf{Q}^K_{j,B}(x;\alpha) = \frac{K^{(d)}_{j,B}(\alpha) + xK^{(d+1)}_{j,B}(\alpha)}{K^{(d)}_{j,B}(\alpha) + K^{(d+1)}_{j,B}(\alpha)} = \frac{x+\xi}{1+\xi}.$$

So the Skeleton value is ξ, the level letter at the floor over the level letter at the largest level, and the coin is $1/(1+\xi) = K^{(d+1)}_{j,B}(\alpha)/K_j(\alpha)$, the probability under $\mathbb{P}_{j,\alpha}(T) = \theta_{j,T}\alpha^T/K_j(\alpha)$ of the bases at level $d+1$ (7.16), that is $\mathbb{P}_{j,\alpha}(N_B = d+1)$. The same computation with the colevel letters gives the Skeleton value $\Psi^{(d^*)}_{j,B}(\alpha)/\Psi^{(d^*+1)}_{j,B}(\alpha)$ and the coin $\Psi^{(d^*+1)}_{j,B}(\alpha)/\Psi_j(\alpha) = \mathbb{P}^*_{j,\alpha}(N^*_B = d^*+1)$, since $\mathbb{P}^*_{j,\alpha}(T) = \theta_{j,T}\alpha^{\mathcal{E}\setminus T}/\Psi_j(\alpha)$.

Let $B = \{e\}$ with e neither a loop nor a coloop of table j. Then $d = 0$ and $r_j(\{e\}) = 1$, so $c = 1$ and $d^* = 0$. The bases at level 0 avoid e and those at level 1 contain it, so $K^{(0)}_{j,\{e\}} = K_{j,\setminus e}(\alpha_R)$ and $K^{(1)}_{j,\{e\}} = \alpha_e K_{j,/e}(\alpha_R)$; the bases at colevel 0 contain e and those at colevel 1 avoid it, so $\Psi^{(0)}_{j,\{e\}} = \Psi_{j,/e}(\alpha_R)$ and $\Psi^{(1)}_{j,\{e\}} = \alpha_e \Psi_{j,\setminus e}(\alpha_R)$ (7.3). The coins are $\alpha_e K_{j,/e}/K_j = \mathbb{P}_{j,\alpha}(e \in T) = R_{j,e}(\alpha)$ and $\alpha_e \Psi_{j,\setminus e}/\Psi_j = \mathbb{P}^*_{j,\alpha}(e \notin T) = R^*_{j,e}(\alpha)$ (7.16). This is the reference, proof of 15.4. □

Theorem 15.6 (The scale in its spectral gaps). *As stated: complex coefficients and letter exponents, expanded about any point r of the axis with $|\xi_\ell - r| < r$ for every ℓ.*

Proof. The left side is the value of the scale integral $\int_0^\infty x^{\kappa-1} \prod_{\ell\in J}(x+\xi_\ell)^{-w_\ell} dx$, which converges since $0 < \operatorname{Re}\kappa < \operatorname{Re}|\mathbf{w}|$ (15.1). For $x \geq 0$ put $q_\ell(x) = (r-\xi_\ell)/(x+r)$, so that $x + \xi_\ell = (x+r)(1-q_\ell(x))$ and $|q_\ell(x)| \leq |r-\xi_\ell|/r = |g_\ell| < 1$.

Expansion. Since $x + r > 0$ and $\operatorname{Re}(1-q_\ell(x)) > 0$, the principal argument of $x+\xi_\ell$ is that of $1-q_\ell(x)$, which lies in $(-\pi/2, \pi/2)$; so $(x+\xi_\ell)^{-w_\ell} = (x+r)^{-w_\ell}(1-q_\ell(x))^{-w_\ell}$ with principal powers, and the binomial series $(1-q)^{-w} = \sum_{n\geq 0} \frac{(w)_n}{n!} q^n$ converges absolutely for $|q| < 1$. Hence

$$x^{\kappa-1} \prod_\ell (x+\xi_\ell)^{-w_\ell} = \sum_{\mathbf{n}\in\mathbb{N}^J} \prod_\ell \frac{(w_\ell)_{n_\ell}}{n_\ell!} (r-\xi_\ell)^{n_\ell}\, x^{\kappa-1}(x+r)^{-|\mathbf{w}|-|\mathbf{n}|}.$$

Term by term. $|(w)_n| = \prod_{i<n}|w+i| \leq \prod_{i<n}(|w|+i) = (|w|)_n$, and $(x+r)^{-|\mathbf{n}|} \leq r^{-|\mathbf{n}|}$. So the moduli of the terms sum to at most

$$x^{\operatorname{Re}\kappa-1}(x+r)^{-\operatorname{Re}|\mathbf{w}|} \prod_\ell \sum_{n\geq 0} \frac{(|w_\ell|)_n}{n!} |g_\ell|^n = x^{\operatorname{Re}\kappa-1}(x+r)^{-\operatorname{Re}|\mathbf{w}|} \prod_\ell (1-|g_\ell|)^{-|w_\ell|},$$

which is integrable on $(0,\infty)$ since $0 < \operatorname{Re}\kappa < \operatorname{Re}|\mathbf{w}|$; so the series may be integrated term by term. For $0 < \operatorname{Re}\kappa < \operatorname{Re} a$ the integral of a linear letter, in the paragraph after 15.1 with $c_0 = r$ and $c_1 = 1$, is

$$\int_0^\infty x^{\kappa-1}(x+r)^{-a} dx = \Gamma \begin{bmatrix} \kappa, & a-\kappa \\ & a \end{bmatrix} r^{\kappa-a},$$

and at $a = |\mathbf{w}| + |\mathbf{n}|$, with $(r-\xi_\ell)^{n_\ell} r^{-n_\ell} = g_\ell^{n_\ell}$, the term of $\mathbf{n}$ is the term of the statement.

Root rate. Let A_M be the sum of the terms with $|\mathbf{n}| = M$, $v = \sum_\ell |w_\ell|$ and $\bar g = \max_\ell |g_\ell|$. Comparing the coefficients of z^M in $\prod_\ell (1-z)^{-|w_\ell|} = (1-z)^{-v}$ gives $\sum_{|\mathbf{n}|=M} \prod_\ell \frac{(|w_\ell|)_{n_\ell}}{n_\ell!} = \frac{(v)_M}{M!}$. The Beta corner of order M is the integral $\int_0^1 x^{\kappa-1}(1-x)^{|\mathbf{w}|+M-\kappa-1}dx$ (3.9), of modulus at most $b_0 = \int_0^1 x^{\operatorname{Re}\kappa-1}(1-x)^{\operatorname{Re}|\mathbf{w}|-\operatorname{Re}\kappa-1}dx < \infty$. So $|A_M| \le |r^{\kappa-|\mathbf{w}|}|\, b_0 \frac{(v)_M}{M!}\bar g^M$, and $\frac{(v)_M}{M!} = \prod_{i=1}^M \left(1+\frac{v-1}{i}\right) \le e^{|v-1|(1+\log M)}$ grows at most polynomially in M. Hence $\limsup_M |A_M|^{1/M} \le \bar g$ (1.1(viii)).

The remaining sentences. A coefficient $\xi_\ell = r$ has $g_\ell = 0$, and every term with $n_\ell > 0$ vanishes. For $0 < \xi_\ell \le r$, $w_\ell > 0$ and $0 < \kappa < |\mathbf{w}|$ every factor of every term is positive, a factor g_ℓ^0 being 1. For positive coefficients write $\xi_{\min}$ and $\xi_{\max}$ for the least and the largest; $|1-\xi/r|$ is largest over $\xi \in [\xi_{\min}, \xi_{\max}]$ at an end, so $\max_\ell |g_\ell| = \max\left(|1-\xi_{\min}/r|, |1-\xi_{\max}/r|\right)$. For $r \le \xi_{\min}$ this is $\xi_{\max}/r - 1$, decreasing in r; for $r \ge \xi_{\max}$ it is $1-\xi_{\min}/r$, increasing in r; for $\xi_{\min} \le r \le \xi_{\max}$ it is the larger of $1-\xi_{\min}/r$, increasing, and $\xi_{\max}/r - 1$, decreasing, which are equal at $r = \frac12(\xi_{\min}+\xi_{\max})$, with the value $\frac{\xi_{\max}-\xi_{\min}}{\xi_{\max}+\xi_{\min}}$. At that r, $|\xi_\ell - r| \le \frac12(\xi_{\max}-\xi_{\min}) < r$ for every ℓ. At $r = \xi_{\max}$ the bound is $1-\xi_{\min}/\xi_{\max}$, the largest coefficient drops out, and the statement is the reference, proof of 15.6. □

Corollary 15.11 (The period closes on the ordering sectors). *As stated: complex data with $\kappa_{\mathcal{E}} = 0$ and every proper wall of positive real part.*

Proof. Sector form. Let Ω be the set of data at which every proper wall has positive real part. It is open and convex, the walls being affine in the data with real coefficients, and it contains points at which $\operatorname{Re}\kappa_{\mathcal{E}} > 0$ as well (raise every mass). By 8.5(ii), valid for all complex exponents, and 8.7, wherever every wall has positive real part

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t}) = \sum_\pi I_\pi, \qquad I_\pi = \int_{[0,1]^{n-1}} \prod_{k=2}^n q_k^{\kappa_{U_k}-1} h_\pi(q)\, dq, \quad h_\pi = L_\pi^{-\kappa_{\mathcal{E}}} \prod_j k_{j,\pi}^{-s_j} \psi_{j,\pi}^{-t_j}.$$

The sector letters are polynomials with nonnegative coefficients and positive constant terms, and $L_\pi \in [1,n]$ on the cube, so h_π is smooth on a neighbourhood of the cube, with every q-derivative continuous in q and the data and entire in the data, and $|h_\pi|$ is bounded on the cube locally uniformly in the data. The tails U_k, $k \ge 2$, of the orders are the nonempty proper sets of marks. So every I_π converges and is holomorphic on Ω, and so is P_F (8.7); Ω being connected, $P_F = \sum_\pi I_\pi$ on Ω. At $\kappa_{\mathcal{E}} = 0$, $h_\pi = \prod_j k_{j,\pi}^{-s_j}\psi_{j,\pi}^{-t_j}$.

The identity and the range. In the sector coordinates $\alpha^T = \rho^{|T|}\prod_k q_k^{N_{U_k}(T)}$, so $k_{j,\pi}(q) = \sum_T \theta_{j,T}\prod_k q_k^{N_{U_k}(T)-d_j(U_k)}$ (8.5(ii)), with exponents in $\mathbb{N}$, all zero only at $T = T^+_{j,\pi}$ (8.3). So $k_{j,\pi}/K_j(\mathbf{1})$ increases in each q_k on the cube, from $\theta_{j,T^+_{j,\pi}}/K_j(\mathbf{1})$ at $q = 0$ to 1 at $q = \mathbf{1}$, and $0 \le 1 - k_{j,\pi}/K_j(\mathbf{1}) \le \lambda$. The identity is the expectation under $\mathbb{P}_{j,\mathbf{1}}$ of $1 - \prod_k q_k^{e_k} = \sum_k \prod_{k'<k} q_{k'}^{e_{k'}}(1-q_k^{e_k})$, $e_k = N_{U_k} - d_j(U_k)$, with $1-q^e = (1-q)\sum_{0\le i<e} q^i$. The same holds for $\psi_{j,\pi}$ with N^*, d_j^* and $T^-_{j,\pi}$, and $\Psi_j(\mathbf{1}) = K_j(\mathbf{1})$. These are statements about the tables alone, as in the reference, proof of 15.11.

Expansion. With $a_j = 1 - k_{j,\pi}/K_j(\mathbf{1})$ and $b_j = 1 - \psi_{j,\pi}/K_j(\mathbf{1})$ in $[0,\lambda]$, $k_{j,\pi}^{-s_j} = K_j(\mathbf{1})^{-s_j}\sum_{n\ge0}\frac{(s_j)_n}{n!}a_j^n$ and $\psi_{j,\pi}^{-t_j} = K_j(\mathbf{1})^{-t_j}\sum_{n\ge0}\frac{(t_j)_n}{n!}b_j^n$, with principal powers of positive numbers. By $|(s)_n| \le (|s|)_n$ the moduli of the terms of the product of these series sum to at most $\prod_j K_j(\mathbf{1})^{-\operatorname{Re}(s_j+t_j)}(1-\lambda)^{-|s_j|-|t_j|}$ on the cube, and $\int \prod_k q_k^{\operatorname{Re}\kappa_{U_k}-1}dq = \prod_k(\operatorname{Re}\kappa_{U_k})^{-1} < \infty$. So the series may be integrated term by term over the cube, which gives the displayed series, convergent.

Terms. By the identity, a_j and b_j are sums, with nonnegative coefficients, of products $(1-q_k)q^{\boldsymbol{\beta}}$, $\boldsymbol{\beta}\in\mathbb{N}^{n-1}$; so $\prod_j a_j^{n_j}b_j^{n'_j}$ is a finite sum, with nonnegative coefficients, of products $\prod_k(1-q_k)^{\gamma_k}q_k^{\beta_k}$, and for $\operatorname{Re}\kappa>0$, $\int_0^1 q^{\kappa+\beta-1}(1-q)^{\gamma}dq=\Gamma\,{}_2{}_1\!\left[\begin{matrix}\kappa+\beta,\ \gamma+1\\ \kappa+\beta+\gamma+1\end{matrix}\right]$ (3.9). For real data with $s_j,t_j\ge 0$ the coefficients $(s_j)_n/n!$ and $(t_j)_n/n!$ and the integrands are nonnegative.

Bound. The terms with $|\mathbf{n}|+|\mathbf{n}'|=M$ have moduli summing to at most

$$\prod_j K_j(\mathbf{1})^{-\operatorname{Re}(s_j+t_j)}\sum_{|\mathbf{n}|+|\mathbf{n}'|=M}\prod_j\frac{(|s_j|)_{n_j}(|t_j|)_{n'_j}}{n_j!\,n'_j!}\,\lambda^M\sum_{\pi}\prod_k(\operatorname{Re}\kappa_{U_k})^{-1},$$

and comparing coefficients of z^M in $\prod_j(1-z)^{-|s_j|}(1-z)^{-|t_j|}=(1-z)^{-w}$ gives $\frac{(w)_M}{M!}$ for the inner sum, $w=\sum_j(|s_j|+|t_j|)$. □

Proposition 15.12 (An enclosure of the period in the field of its data). *As stated: weights, masses and exponents in a subfield k of $\mathbb{R}$, the exponents of any sign.*

Proof. The data are real, so by the hypotheses of 15.11 every proper wall is positive, and every $\kappa_{U_k}>0$.

(i) The weights lie in k, so the coefficients of the sector letters, sums of weights (8.5(ii)), and $K_j(\mathbf{1})$ lie in k, and $a_{j,\pi},b_{j,\pi}\in k[q]$. For $s\in k$ and $n\in\mathbb{N}$, $(s)_n/n!\in k$. So $f_{\pi,M}=\sum_{|\mathbf{n}|+|\mathbf{n}'|=M}\prod_j\frac{(s_j)_{n_j}(t_j)_{n'_j}}{n_j!\,n'_j!}a_{j,\pi}^{n_j}b_{j,\pi}^{n'_j}$, the coefficient of ζ^M in the product of the binomial series, lies in $k[q]$. Each κ_{U_k} is an integer combination of masses and exponents and lies in k, and $\int_{[0,1]^{n-1}}\prod_k q_k^{\kappa_{U_k}-1+\beta_k}dq=\prod_k(\kappa_{U_k}+\beta_k)^{-1}\in k$ for $\boldsymbol{\beta}\in\mathbb{N}^{n-1}$; so $I_{\pi,M}\in k$. Grouping the absolutely convergent series of 15.11 by $M=|\mathbf{n}|+|\mathbf{n}'|$ gives the identity. When $s_j,t_j\ge 0$ the coefficients are nonnegative, and $a_{j,\pi},b_{j,\pi}\ge 0$ on the cube, so $I_{\pi,M}\ge 0$.

(ii) On the cube $0\le a_{j,\pi},b_{j,\pi}\le\lambda_\pi$ (15.11), so by $|(s)_n|\le(|s|)_n$ and the coefficient identity of the proof of 15.11, $|f_{\pi,M}|\le\frac{(w)_M}{M!}\lambda_\pi^M$ and $|I_{\pi,M}|\le\prod_k\kappa_{U_k}^{-1}\frac{(w)_M}{M!}\lambda_\pi^M$. The ratio of consecutive bounds is $\frac{w+M}{M+1}\lambda_\pi$, and $M\mapsto\frac{w+M}{M+1}$ is nonincreasing for $w\ge 1$ and below 1 for $w<1$; so for $M\ge Q+1$ the ratio is at most $r_{\pi,Q}<1$, and summing the geometric majorant gives $\big|\sum_{M>Q}I_{\pi,M}\big|\le\operatorname{err}_{\pi,Q}$. The numbers w, λ_π, $r_{\pi,Q}$ and $\operatorname{err}_{\pi,Q}$ lie in k, an ordered subfield of $\mathbb{R}$ being closed under $|\cdot|$ and under maxima of finitely many elements. As $Q\to\infty$, $r_{\pi,Q}\to\lambda_\pi<1$, and $\frac{(w)_{Q+1}}{(Q+1)!}\lambda_\pi^{Q+1}\to 0$, the factor $\frac{(w)_{Q+1}}{(Q+1)!}$ growing at most polynomially; so $\operatorname{err}_{\pi,Q}\to 0$. With $P^{\le Q}=\sum_\pi\sum_{M\le Q}I_{\pi,M}\in k$, the left side of (i) lies between $P^{\le Q}-\sum_\pi\operatorname{err}_{\pi,Q}$ and $P^{\le Q}+\sum_\pi\operatorname{err}_{\pi,Q}$, and for $s_j,t_j\ge 0$, the remainders being nonnegative, between $P^{\le Q}$ and $P^{\le Q}+\sum_\pi\operatorname{err}_{\pi,Q}$.

(iii) $\partial_\zeta\log f=\sum_i w_iA_i/(1-\zeta A_i)$; multiply by $f\prod_i(1-\zeta A_i)$. Comparing the coefficients of ζ^M on the two sides gives a linear recurrence for the coefficients of f, with coefficients polynomial in M and in the A_i. With rational data this is the reference, proof of 15.12. □

Theorem 15.14 (Continued Beta corners). *As stated: complex data, every index off the nonpositive integers, several indices of nonpositive real part at once.*

Proof. A continuation as a linear functional. For $\kappa\in\mathbb{C}$ and $h\in\mathbb{N}$ with $\operatorname{Re}\kappa>-h-1$ and $\kappa\notin\{0,-1,\dots,-h\}$, and f smooth on $[0,1]$, 8.4 with $m=1$ and $M=h+1$ gives the continuation in κ of $\int_0^1 x^{\kappa-1}f\,dx$:

$$\mathcal{C}(\kappa;f)=\int_0^1 x^{\kappa-1}\big(f-\operatorname{Tay}_h f\big)dx+\sum_{l\le h}\frac{f^{(l)}(0)}{l!\,(\kappa+l)},$$

Tay_h taking the Taylor polynomial of degree h at 0; it is the finite part $\mathrm{Reg}\int_0^1 x^{\kappa-1}f\,dx$ (1.8). By Taylor's formula $|f-\mathrm{Tay}_h f|\le \frac{x^{h+1}}{(h+1)!}\sup|f^{(h+1)}|$, so

$$|\mathcal{C}(\kappa;f)|\le \frac{\sup|f^{(h+1)}|}{(h+1)!\,(\mathrm{Re}\,\kappa+h+1)}+\sum_{l\le h}\frac{|f^{(l)}(0)|}{l!\,|\kappa+l|}:$$

$\mathcal{C}(\kappa;\cdot)$ is linear and bounded by a constant times the largest of the sup-norms of $f,\dots,f^{(h+1)}$. On a cube $[0,1]^m$, with a number $L_k\in\mathbb{N}$ for each coordinate, $\mathrm{Re}\,x_k+L_k>0$ and $x_k\notin\{0,\dots,1-L_k\}$, 8.4 repeated in each coordinate gives the continuation of $\int\prod_k q_k^{x_k-1}f\,dq$ as a finite sum, over the sets A of coordinates and the $\mathbf{l}$ with $l_k<L_k$ for $k\in A$, of $\prod_{k\in A}(x_k+l_k)^{-1}$ times the integral over the other coordinates of $\prod_{k\notin A}q_k^{x_k-1}$ against $\prod_{k\notin A}(1-\mathrm{Tay}_{L_k-1})$ applied to $\partial^{\mathbf{l}}_{q_A}f/\mathbf{l}!$ at $q_A=0$ (as in 8.6), with $\mathrm{Tay}_{-1}=0$. Taylor's formula in each coordinate outside A bounds each term by a constant, depending only on the x_k, times the largest sup-norm of the derivatives of f of total order at most $L=\sum_k L_k$; so this continuation is again linear and bounded on $C^L([0,1]^m)$, and it is the iterated finite part, by 1.8 in one coordinate at a time.

Leibniz bounds. Let finitely many functions f_i be smooth on a cube, with $0\le f_i\le\lambda$, $0<\lambda<1$, and let $D\ge 1$ bound their derivatives of order at most L. For a multi-index $\mathbf{n}$ over the i and $f_{\mathbf{n}}=\prod_i f_i^{n_i}$, a derivative of total order $l\le L$ distributes over the $|\mathbf{n}|$ factors in at most $|\mathbf{n}|^l$ ways, each product having at most l differentiated factors, each bounded by D, and the others bounded by λ; so $|\partial^{\boldsymbol\beta}f_{\mathbf{n}}|\le D^l|\mathbf{n}|^l\lambda^{|\mathbf{n}|-l}$ for $|\boldsymbol\beta|=l$. Hence the sum, over the $\mathbf{n}$ with $|\mathbf{n}|=M$, of $\prod_i\frac{|(w_i)_{n_i}|}{n_i!}$ times the C^L-norm of $f_{\mathbf{n}}$ is at most $\frac{(w)_M}{M!}D^L(1+M)^L\lambda^{M-L}$, $w=\sum_i|w_i|$, by the coefficient identity of the proof of 15.6. These bounds are summable over M, so $\sum_{\mathbf{n}}\prod_i\frac{(w_i)_{n_i}}{n_i!}f_{\mathbf{n}}$ converges in C^L, to $\prod_i(1-f_i)^{-w_i}$; a bounded linear functional on C^L commutes with the sum, and applied to $f_{\mathbf{n}}$ it is at most a constant times $D^L(1+|\mathbf{n}|)^L\lambda^{|\mathbf{n}|-L}$. If $\lambda=0$ every f_i vanishes and only $\mathbf{n}=0$ contributes.

The two sectors of a scale. In 15.9 take $f_i=1-\mathsf{Q}_{S,i}(\cdot;\alpha)$ on $[0,1]$: each $\mathsf{Q}_{S,i}$ has nonnegative coefficients, positive constant term and value 1 at $x=1$ (12.10), so $0\le f_i\le 1-\mathsf{Q}_{S,i}(0;\alpha)\le\lambda_S$ there, and $\prod_i\mathsf{Q}_{S,i}^{-w_i}=\sum_{\mathbf{n}}\prod_i\frac{(w_i)_{n_i}}{n_i!}f_{\mathbf{n}}$. Let κ be the index of the sector, not a nonpositive integer. If $\mathrm{Re}\,\kappa>0$, take $\mathcal{C}(\kappa;f)=\int_0^1 x^{\kappa-1}f\,dx$, bounded by $\sup|f|/\mathrm{Re}\,\kappa$, with $L=0$; otherwise take h as in the statement and $L=h+1$. By the preceding paragraph,

$$\mathcal{C}\Big(\kappa;\prod_i\mathsf{Q}_{S,i}^{-w_i}\Big)=\sum_{\mathbf{n}}\prod_i\frac{(w_i)_{n_i}}{n_i!}\,\mathcal{C}(\kappa;f_{\mathbf{n}}),$$

the terms of total order M having moduli summing to at most $\frac{(w)_M}{M!}\lambda_S^M$ times a polynomial in M of degree L, $w=\sum_j(|s_j|+|t_j|)$. The left side is the finite part of the sector integral and its continuation in κ. By 15.8, $f_{\mathbf{n}}=(1-x)^{|\mathbf{n}|}\prod_i\mathsf{Q}_{S,i,>}^{n_i}$, a polynomial, and $\mathcal{C}\big(\kappa;x^k(1-x)^{|\mathbf{n}|}\big)$ is the continuation of $\int_0^1 x^{\kappa+k-1}(1-x)^{|\mathbf{n}|}dx=\Gamma\begin{bmatrix}\kappa+k,\ |\mathbf{n}|+1\\ \kappa+k+|\mathbf{n}|+1\end{bmatrix}$ (3.9), the meromorphic stacked Gamma, finite since $\kappa+k\notin-\mathbb{N}$. So the series of 15.9(ii), with these Beta corners, converges to the finite part, with the stated bound. By 15.9(i) the scale integral is the product of the letters at α and the sum of the two sectors at the indices κ_B and κ_B^{top}, and its continuation in the data is the same expression with the sectors continued.

The ordering sectors. By the first step of the proof of 15.11 and 8.4, $P_F=\sum_\pi I_\pi$ as meromorphic functions of the data, each I_π continued by 8.4, whose formula expresses the continuation at a point through the values of h_π at that point; on the balance wall $h_\pi=\prod_j k_{j,\pi}^{-s_j}\psi_{j,\pi}^{-t_j}$. At a

point of the balance wall at which no proper wall is a nonpositive integer, take for an order π the numbers $L_k = h_k + 1$ when $\operatorname{Re}\kappa_{U_k} \le 0$, with $-h_k - 1 < \operatorname{Re}\kappa_{U_k} \le -h_k$, and $L_k = 0$ otherwise. With f running over the a_j, b_j of the proof of 15.11, in $[0,\lambda]$ on the cube, the preceding paragraphs give the continuation of I_π as the series of 15.11 for π, each integral replaced by its continuation; and the continuation of $\int \prod_k q_k^{\kappa_{U_k}+\beta_k-1}(1-q_k)^{\gamma_k}dq$ is the product over k of the continued Beta corners, each finite since $\kappa_{U_k} + \beta_k \notin -\mathbb{N}$. The terms of total order M have moduli summing to at most $\frac{(w)_M}{M!}\lambda^M$ times a polynomial in M of degree $\sum_k L_k$, and the tails of one order being distinct proper sets, $\sum_k L_k$ is at most the sum of the integers $h+1$ over the proper walls of real part at most 0. Every proper set of marks is a tail of some order, so the sector series computes P_F at every point of the balance wall off the pole hyperplanes, with no positivity of the walls. For one real index in $(-h-1, -h)$ this is the reference, proof of 15.14. □

Corollary 15.16 (A loop or coloop in every table). *As stated: a set of marks, each a loop or a coloop in every table.*

Proof. For a table j let p_j be the set of the marks of A that are coloops of table j. Every basis contains every coloop and avoids every loop, so $T \cap A = p_j$ for every basis T of table j. The sets $T \setminus A$ are then the bases of the table on $\mathcal{E} \setminus A$ obtained from table j by contracting the marks of p_j and deleting those of $A \setminus p_j$, one mark at a time (7.3; a loop is never a coloop, so each step is a table), with the weights $\theta_{j,T}$; with K'_j, Ψ'_j its Foreman polynomials and $\alpha' = \alpha_{\mathcal{E}\setminus A}$,

$$K_j(\alpha) = \alpha_A^{p_j} K'_j(\alpha'), \qquad \Psi_j(\alpha) = \alpha_A^{A\setminus p_j}\Psi'_j(\alpha'),$$

since $\mathcal{E} \setminus T = (A \setminus p_j) \sqcup \big((\mathcal{E} \setminus A) \setminus (T \setminus A)\big)$. So the integrand of $J_F(\mathbf{m};\mathbf{s},\mathbf{t})$ is the product of

$$\prod_{e\in A} \alpha_e^{m_e - 1 - \sum_j (s_j \mathbf{1}[e\in p_j] + t_j \mathbf{1}[e\notin p_j])} e^{-\alpha_e}$$

and of the integrand of $J_{F'}(\mathbf{m}|_{\mathcal{E}\setminus A};\mathbf{s},\mathbf{t})$. With $s_j = \sigma_j + \delta_j$, $t_j = \sigma_j - \delta_j$ and $m_e = \mu_e + \sigma$, the exponent of α_e is $\mu_e - \sum_j \eta_{j,e}\delta_j - 1$. The integrand is a product of functions of disjoint sets of variables, so by Tonelli on the modulus its integral converges exactly when every factor's does, and then, by Fubini, it is the product of the factors' integrals, with $\int_0^\infty \alpha_e^{\nu-1}e^{-\alpha_e}d\alpha_e = \Gamma(\nu)$ for $\operatorname{Re}\nu > 0$. As meromorphic functions the identity persists (8.5(iii)). For one mark this is the reference, proof of 15.16, there read through 15.15 at $B = \{e\}$. □

50.16 Chapter 16: integrals, expectations and the Foreman procedure

Proposition 16.5 (Snips are completions). *As stated: (iii) at every imbalance, through the appended list $\binom{B}{1}$ of the singletons of the bunch.*

Proof. Items (i) and (ii) are the reference, proof of 16.5. For (iii) let $R = \mathcal{E} \setminus B$.

Projectivity. The family word W is homogeneous of degree $-\sum_j(s_j r_j + t_j r_j^*) = \kappa_{\mathcal{E}} - m_{\mathcal{E}}$ (8.1), so $\omega = \alpha^{\mathbf{m}-\mathbf{1}} W\, d\alpha$ is multiplied by $\lambda^{\kappa\varepsilon}$ under $\alpha \mapsto \lambda\alpha$, and $|\alpha_B|^{-\kappa\varepsilon}\omega$ is unchanged: it is projective (1.1(vii)). On the section $|\alpha_B| = 1$ the multiplier is 1, so the two forms induce the same form there.

The appended table. The sets $\{e\}$, $e \in B$, have one element each and the exchange property, two of them differing in one mark; so they are the bases of a table on $\mathcal{E}$ of rank 1 (7.1), in which

the marks of R lie in no basis, and with unit weights its basis polynomial is $\sum_{e\in B}\alpha_e = |\alpha_B|$. So $|\alpha_B|^{-\kappa_\varepsilon}W$ is the family word of F' at the exponents $\big((\mathbf{s},\kappa_\mathcal{E}),(\mathbf{t},0)\big)$, the appended table carrying $(\kappa_\mathcal{E},0)$, and $|\alpha_B|^{-\kappa_\varepsilon}\omega$ is the form of F' at the masses $\mathbf{m}$.

Walls. For the appended table $d_0(S) = \min_{e\in B}|\{e\}\cap S| = \mathbf{1}[B\subseteq S]$ (7.13), and its exponent on Ψ is 0; so by 8.1 the walls of F' at $\mathbf{m}$ are $\kappa_S - \kappa_\mathcal{E}\mathbf{1}[B\subseteq S]$, and its imbalance is $\kappa_\mathcal{E} - \kappa_\mathcal{E}\cdot 1 = 0$, the appended table having rank 1.

Value. $|\alpha_B|$ is positive and homogeneous of degree one on the orthant. Where every proper wall of F' has positive real part, the period of F' converges, and the integral of its form over the section $\{|\alpha_B|=1\}$ is that period (8.7); this is the display.

The cases. For $B=\{g\}$ the appended table has the one basis $\{g\}$ and the letter α_g, and $\alpha_g^{-\kappa_\varepsilon}W\,d\alpha_\mathbf{m} = W\,d\alpha_{\mathbf{m}-\kappa_\mathcal{E}\mathbf{e}_g} = \omega_{\mathbf{m}^{(g)}}$ (16.4): this is (i). For $B=\mathcal{E}$ the appended table is the list $\binom{\mathcal{E}}{1}$, and the statement is 16.3. For $k=-\kappa_\mathcal{E}\in\mathbb{N}$, $k\geq 1$: on the section $\omega = |\alpha_B|^k\omega$, $|\alpha_B|^k = \sum_{|\mathbf{n}|=k}\binom{k}{\mathbf{n}}\alpha_B^\mathbf{n}$, and $\alpha_B^\mathbf{n}\omega = W\,d\alpha_{\mathbf{m}+\mathbf{n}}$ is the completion along $\mathbf{n}/k$ (16.4: $\mathbf{m}-\kappa_\mathcal{E}\mathbf{n}/k = \mathbf{m}+\mathbf{n}$), projective, whose integral over the section is $P_F(\mathbf{m}+\mathbf{n};\mathbf{s},\mathbf{t})$ wherever that period converges (8.7). This last case is the reference, proof of 16.5(iii). □

Corollary 16.6 (The period fibres over the scale of a bunch). *As stated: every section $\{h(\alpha_R)=1\}$ of the room, and off the balance wall.*

Proof. For a positive function h on an orthant $\mathbb{R}^X_{>0}$, homogeneous of degree one, write λ_h for the measure on $\Sigma_h=\{\beta:\ h(\beta)=1\}$ with $d\alpha = \rho^{|X|-1}d\rho\,d\lambda_h(\beta)$ under the bijection $(\rho,\beta)\mapsto\rho\beta$ of $(0,\infty)\times\Sigma_h$ onto $\mathbb{R}^X_{>0}$: the measure of 16.2 (the reference, proof of 16.2). For $h=\alpha_g$ it is the Lebesgue measure in the coordinates α_e, $e\neq g$, at $\alpha_g=1$, and for $h=|\alpha|$ it is $d\omega$ (2.7).

Let h be a function of α_R as in the statement, and put $\tilde h(\alpha)=h(\alpha_R)$ on $\mathbb{R}^\mathcal{E}_{>0}$, positive and homogeneous of degree one. The map $(\rho,\beta_B,\beta_R)\mapsto(\rho\beta_B,\rho\beta_R)$, $\beta_B\in\mathbb{R}^B_{>0}$, $\beta_R\in\Sigma_h$, is a bijection onto $\mathbb{R}^\mathcal{E}_{>0}$, with $d\alpha_R = \rho^{|R|-1}d\rho\,d\lambda_h(\beta_R)$ and $d\alpha_B = \rho^{|B|}d\beta_B$ at fixed ρ. So $d\alpha = \rho^{n-1}d\rho\,d\beta_B\,d\lambda_h(\beta_R)$, and the measure of the section $\{\tilde h=1\}$ is $d\beta_B\,d\lambda_h(\beta_R)$. The integral of $W\,d\alpha_\mathbf{m}$ over it is

$$\int_{\Sigma_h}\beta_R^{\mathbf{m}|_R-\mathbf{1}}\int_{\mathbb{R}^B_{>0}}\beta_B^{\mathbf{m}|_B-\mathbf{1}}\prod_j K_j(\beta_B,\beta_R)^{-s_j}\Psi_j(\beta_B,\beta_R)^{-t_j}\,d\beta_B\,d\lambda_h(\beta_R),$$

by Tonelli on the modulus, which is the same integrand at the real parts of the data, and then Fubini. With $\beta_B = xu$, $x>0$, $u\in\Delta_B$, $\beta_B^{\mathbf{m}|_B-\mathbf{1}}d\beta_B = x^{m_B-1}u^{\mathbf{m}|_B-\mathbf{1}}dx\,d\omega_B(u)$ (2.7), so the inner integral is $\int_{\Delta_B}u^{\mathbf{m}|_B-\mathbf{1}}\,\mathrm{Sc}_B(u,\beta_R;\mathbf{m};\mathbf{s},\mathbf{t})\,d\omega_B(u)$, with the scale integral of 15.3 at the gauge (u,β_R). This is the display.

The scale integral converges exactly when $\mathrm{Re}\,\kappa_B>0$ and $\mathrm{Re}\,\kappa_B^{\mathrm{top}}>0$ (15.3), conditions on the data alone; by Tonelli it converges at almost every (u,β_R), hence at every point, and there it is the product of 15.3. On the balance wall the form is projective and its integral over every section is the period (8.7). At $h=\alpha_g$ the integral over $\{\alpha_g=1\}$ is $P_F(\mathbf{m}^{(g)};\mathbf{s},\mathbf{t})$ wherever it converges (16.5(i)), and λ_h is the Lebesgue measure in α_{R-g} at $\alpha_g=1$; at $h=|\alpha_R|$, $\Sigma_h=\Delta_R$ and $\lambda_h=d\omega_R$. At $h=\alpha_g$ on the balance wall this is the reference, proof of 16.6. □

Lemma 16.9 (The period is meromorphic in the data). *As stated, for every family and all complex data.*

Proof. Meromorphy. By the first step of the proof of 15.11 above, which uses neither connectedness nor real data, $P_F=\sum_\pi I_\pi$ on the open convex set Ω of the data at which every proper wall has positive real part, with $I_\pi = \int_{[0,1]^{n-1}}\prod_{k=2}^n q_k^{\kappa_{U_k}-1}h_\pi\,dq$ and $h_\pi = L_\pi^{-\kappa_\varepsilon}\prod_j k_{j,\pi}^{-s_j}\psi_{j,\pi}^{-t_j}$ smooth near

the closed cube, its derivatives continuous in the variables and the data and entire in the data. By 8.4 each I_π extends to a meromorphic function of the data, a quotient of a holomorphic function by products of affine functions $\kappa_{U_k}+i$, $i\in\mathbb{N}$, with poles only on the hyperplanes $\kappa_{U_k}=-i$. Every nonempty proper set of marks is a tail of some order, and no tail is $\mathcal{E}$. So P_F is meromorphic in the masses and the exponents, with poles only where a proper wall is a nonpositive integer.

The restriction to the balance wall. For a nonempty proper U the affine function κ_U+i of the data has the part m_U in the masses, which is not proportional to the part $m_{\mathcal{E}}$ of $\kappa_{\mathcal{E}}$; so the hyperplane $\kappa_U=-i$ is not the balance wall $\{\kappa_{\mathcal{E}}=0\}$, and it meets the balance wall in a hyperplane of it. Near every point of the balance wall P_F is a quotient of a holomorphic function by a product of such affine functions, none vanishing identically on the balance wall; so the restriction of P_F to the balance wall is meromorphic, with poles only where a proper wall is a nonpositive integer. □

Proposition 16.12 (The form of a compound at one point). *As stated, for any number $q\ge 2$ of parts.*

Proof. The form. Write $r_{j,i}$ for the rank of the restriction of table j to $\mathcal{E}_i$, so that $K_{j,i}$ is homogeneous of degree $r_{j,i}$, $\Psi_{j,i}$ of degree $|\mathcal{E}_i|-r_{j,i}$, and $\kappa_i=m_{\mathcal{E}_i}-\sum_j\big(s_jr_{j,i}+t_j(|\mathcal{E}_i|-r_{j,i})\big)$; summing over i, $\sum_i\kappa_i=\kappa_{\mathcal{E}}=0$. The section $\{|\alpha_q|=1\}$ carries the measure $\prod_{i<q}d\alpha_i\,d\omega_{\mathcal{E}_q}(u_q)$, by the computation in the proof of 16.6 above with the room there replaced by $\mathcal{E}_q$. For $i<q$, $\alpha_i=\rho_iu_i$ gives $\alpha_i^{\mathbf{m}_i-\mathbf{1}}d\alpha_i=\rho_i^{m_{\mathcal{E}_i}-1}u_i^{\mathbf{m}_i-\mathbf{1}}d\rho_i\,d\omega_{\mathcal{E}_i}(u_i)$ (2.7), $K_{j,i}(\rho_iu_i)=\rho_i^{r_{j,i}}K_{j,i}(u_i)$ and $\Psi_{j,i}(\rho_iu_i)=\rho_i^{|\mathcal{E}_i|-r_{j,i}}\Psi_{j,i}(u_i)$. The powers of ρ_i collect to $\rho_i^{\kappa_i-1}$, which gives the displayed form.

(i) For real κ, $\int_0^\infty\rho^{\kappa-1}d\rho$ diverges, at ∞ if $\kappa\ge0$ and at 0 if $\kappa\le0$. The form is positive, and by Tonelli its integral is the product of the $q-1$ integrals $\int_0^\infty\rho_i^{\kappa_i-1}d\rho_i$, each infinite, and of the q shape integrals, each positive; so it is infinite.

(ii) A primitive of $\rho^{\kappa-1}$ is ρ^κ/κ, or $\log\rho$ at $\kappa=0$. It is its own log-power expansion at 0 and at ∞, with no term $\rho^0\log^0\rho$, so both regularized limits are 0 and the finite part is 0 (1.5).

(iii) At $\mathbf{m}(\boldsymbol{\eta})$, $\kappa_i=\kappa_{F_i}(\mathbf{m}_i^0)+i\eta_i|w_i|=i\eta_i$, and $\sum_i\kappa_i=0$ since $\sum_i\eta_i=0$. The walls of F_i at $\mathbf{m}_i^0+i\eta_iw_i$ have the real parts of those at $\mathbf{m}_i^0$, positive, so $f(\boldsymbol{\eta}')=\prod_{i=1}^qP_{F_i}(\mathbf{m}_i^0+i\eta_iw_i;\mathbf{s},\mathbf{t})$, with $\boldsymbol{\eta}'=(\eta_1,\dots,\eta_{q-1})$ and $\eta_q=-\sum_{i<q}\eta_i$, is a smooth function of $\boldsymbol{\eta}'$, each period being holomorphic in the masses there (8.7). In $y_i=\log\rho_i$, $\rho_i^{\kappa_i-1}d\rho_i=e^{i\eta_iy_i}dy_i$. For a test function H of $\boldsymbol{\eta}'$ of compact support, the integral of the form against H, taken over the shapes, then over $\boldsymbol{\eta}'$, then over $\mathbf{y}=(y_1,\dots,y_{q-1})$, is

$$\int_{\mathbb{R}^{q-1}}\int_{\mathbb{R}^{q-1}}H(\boldsymbol{\eta}')f(\boldsymbol{\eta}')\,e^{i\langle\boldsymbol{\eta}',\mathbf{y}\rangle}\,d\boldsymbol{\eta}'\,d\mathbf{y}=(2\pi)^{q-1}H(0)f(0),$$

by Fourier inversion for the smooth function Hf of compact support, whose Fourier transform is integrable; and $f(0)=\prod_iP_{F_i}(\mathbf{m}_i^0;\mathbf{s},\mathbf{t})$. For $q=2$ this is the reference, proof of 16.12. □

Lemma S4. *Let S be a nonempty proper set of marks of a family F on $\mathcal{E}$ with $c_j(S)=0$ in every active table, and put $S'=\mathcal{E}\setminus S$.*

(i) In every active table j, every basis meets S in $r_j(S)$ marks and S' in $r_j(S')$ marks; the bases of $\mathcal{B}_j|S$ and of $\mathcal{B}_j|S'$ are the sets $T\cap S$ and $T\cap S'$, $T\in\mathcal{B}_j$; and $X\sqcup Y\in\mathcal{B}_j$ for every basis X of $\mathcal{B}_j|S$ and every basis Y of $\mathcal{B}_j|S'$.

(ii) In this lemma write

$$I_S(\mathbf{m};\mathbf{s},\mathbf{t})=\int_{\Delta_S\times\Delta_{S'}}\alpha^{\mathbf{m}-\mathbf{1}}\prod_jK_j(\alpha)^{-s_j}\Psi_j(\alpha)^{-t_j}\,d\omega_S\,d\omega_{S'}.$$

It converges, and is holomorphic in the data, wherever $\operatorname{Re}\kappa_U > 0$ *for every nonempty proper subset* U *of* S *and every nonempty proper subset* U *of* S'*; and it extends to a meromorphic function of the data whose poles lie on the hyperplanes* $\kappa_U = -i$, $i \in \mathbb{N}$, U *a nonempty proper subset of* S *or of* S'.

(iii) Wherever every proper wall has positive real part, $\kappa_{\mathcal{E}} = \kappa_S + \kappa_{S'}$ *has positive real part and* $J_F(\mathbf{m};\mathbf{s},\mathbf{t}) = \Gamma(\kappa_S)\Gamma(\kappa_{S'})\, I_S(\mathbf{m};\mathbf{s},\mathbf{t})$.

Proof. (i) Fix an active table j. By 7.13 the numbers $|T\cap S|$ fill $\{d_j(S),\dots,r_j(S)\}$, a single value since $c_j(S)=0$; so every basis meets S in $r_j(S)$ marks and S' in $r_j - r_j(S)$ marks, a constant, which is then $r_j(S')$. By 7.5 the bases of $\mathcal{B}_j|S$ are the sets $T\cap S$ with $|T\cap S| = r_j(S)$, that is all of them, and likewise for S'. Let $X = T_1\cap S$ and $Y = T_2\cap S'$ for bases T_1, T_2; induct on $k = |(T_2\cap S)\setminus X|$. If $k=0$, then $T_2\cap S\subseteq X$, both of size $r_j(S)$, so $T_2 = X\sqcup Y$. If $k>0$, take $a\in (T_2\cap S)\setminus X$; then $a\notin T_1$. The exchange property (7.1) gives $b\in T_1\setminus T_2$ with $T_3 = (T_2\setminus\{a\})\cup\{b\}$ a basis. As $|T_3\cap S| = r_j(S) = |T_2\cap S|$ and $a\in S$, $b\in S$, so $b\in X\setminus T_2$. Then $T_3\cap S' = Y$ and $|(T_3\cap S)\setminus X| = k-1$, and by induction $X\sqcup Y$ is a basis.

Homogeneity in each block. By (i), for an active table j, $K_j(\rho\alpha_S,\rho'\alpha_{S'}) = \rho^{r_j(S)}\rho'^{r_j(S')}K_j(\alpha)$ and $\Psi_j(\rho\alpha_S,\rho'\alpha_{S'}) = \rho^{|S|-r_j(S)}\rho'^{|S'|-r_j(S')}\Psi_j(\alpha)$. For $U\in\{S,S'\}$, $c_j(U) = 0$ (7.13: $c_j(S') = c_j(S)$), so $d_j(U) = r_j(U)$ and $d_j^*(U) = |U| - r_j(U)$ (7.12). An inactive table enters with the exponents 0. So with $g(U) = \sum_j \big(s_j d_j(U) + t_j d_j^*(U)\big) = m_U - \kappa_U$, the function $\phi(\alpha) = \alpha^{\mathbf{m}-\mathbf{1}}\prod_j K_j(\alpha)^{-s_j}\Psi_j(\alpha)^{-t_j}$ has

$$\phi(\rho\alpha_S,\rho'\alpha_{S'}) = \rho^{\kappa_S-|S|}\rho'^{\kappa_{S'}-|S'|}\phi(\alpha),$$

and $|\phi|$ is the same function at the real parts of the data.

(iii) With $\alpha_S = \rho u$ and $\alpha_{S'} = \rho' u'$ (2.7 in each block), $d\alpha = \rho^{|S|-1}\rho'^{|S'|-1}d\rho\, d\rho'\, d\omega_S(u)\, d\omega_{S'}(u')$, and the integrand of J_F becomes $\rho^{\kappa_S-1}e^{-\rho}\rho'^{\kappa_{S'}-1}e^{-\rho'}\phi(u,u')$. Wherever every proper wall has positive real part, $\operatorname{Re}\kappa_{\mathcal{E}} = \operatorname{Re}\kappa_S + \operatorname{Re}\kappa_{S'} > 0$, by 8.16, $c_j(S) = 0$ holding in every table with $\sigma_j\neq 0$, these being active. Then every wall has positive real part, and J_F at the real parts of the data is finite (8.5(i)); by Tonelli it is $\Gamma(\operatorname{Re}\kappa_S)\Gamma(\operatorname{Re}\kappa_{S'})$ times the integral of $|\phi|$ over $\Delta_S\times\Delta_{S'}$, which is therefore finite, and Fubini gives $J_F = \Gamma(\kappa_S)\Gamma(\kappa_{S'})I_S$.

(ii) *Charts.* For a finite set X, a mark $x\in X$ and a function f on $\mathbb{R}^X_{>0}$, homogeneous of degree $-|X|$ and nonnegative or integrable on Δ_X, $\int_{\Delta_X} f\, d\omega_X = \int f|_{\beta_x=1}\, d\beta_{X-x}$, and the same holds on the cones over subsets of Δ_X and their traces on the chart: for a nonnegative function υ on $(0,\infty)$ with $\int_0^\infty \upsilon(\rho)\, d\rho/\rho = 1$, both sides equal $\int_{\mathbb{R}^X_{>0}} f(\alpha)\upsilon(|\alpha|)\, d\alpha$, by 2.7 on the left, and on the right by the change of variables $\alpha = \rho(1,\beta)$, $d\alpha = \rho^{|X|-1}d\rho\, d\beta$, with $\int_0^\infty \upsilon(\rho|(1,\beta)|)\, d\rho/\rho = 1$. The function $\psi(\alpha) = |\alpha_S|^{-\kappa_S}|\alpha_{S'}|^{-\kappa_{S'}}\phi(\alpha)$ is homogeneous of degree $-|S|$ in α_S and $-|S'|$ in $\alpha_{S'}$, and equal to ϕ on $\Delta_S\times\Delta_{S'}$.

For an order π of S, with tails $U_k = \{\pi(k),\dots,\pi(|S|)\}$, $2\le k\le |S|$, use on the chart $\beta_{\pi(1)} = 1$ the coordinates $\beta_{\pi(k)} = q_2\cdots q_k$, $q\in(0,1]^{|S|-1}$, which cover the trace of the sector $\{\beta_{\pi(1)}\ge\cdots\ge\beta_{\pi(|S|)}\}$; the exponent of q_k in β^X is $|X\cap U_k|$, $d\beta_{S-\pi(1)} = \prod_k q_k^{|S|-k}dq$, $\beta^{\mathbf{m}|_S-\mathbf{1}}d\beta_{S-\pi(1)} = \prod_k q_k^{m_{U_k}-1}dq$, and $|\beta| = L_\pi(q) = \sum_{i=1}^{|S|}\prod_{k=2}^{i} q_k \in [1,|S|]$. Likewise π', U'_l, q' and $L_{\pi'}$ on S'. Decomposing each simplex into its sectors, and applying the identity above in each block, by Tonelli on the modulus and then Fubini,

$$I_S = \sum_{\pi,\pi'}\int \prod_k q_k^{m_{U_k}-1}\prod_l q_l'^{m_{U'_l}-1}\, L_\pi(q)^{-\kappa_S}L_{\pi'}(q')^{-\kappa_{S'}}\prod_j K_j(\beta,\beta')^{-s_j}\Psi_j(\beta,\beta')^{-t_j}\, dq\, dq',$$

the integral over $(0,1]^{|S|-1}\times(0,1]^{|S'|-1}$.

The letters on a product of sectors. Fix an active table j. By (i) and 7.5, $\mathcal{B}_j|S$ is a table on S, and by 8.3 for π it has bases $X^\pm$ with $|X^+\cap U_k|=\min_X|X\cap U_k|$ and $|U_k\setminus X^-|=\min_X|U_k\setminus X|$, the minima over its bases; by (i) these minima are $\min_T|T\cap U_k|=d_j(U_k)$ and $\min_T|U_k\setminus T|=d_j^*(U_k)$ (7.13). Likewise $\mathcal{B}_j|S'$ has bases $Y^\pm$ for π'. For a basis T, $\beta^{T\cap S}/\beta^{X^+}=\prod_k q_k^{|T\cap U_k|-d_j(U_k)}$ with exponents in $\mathbb{N}$, and likewise on S'. So

$$K_j(\beta,\beta')=\prod_k q_k^{d_j(U_k)}\prod_l {q_l'}^{d_j(U_l')}\,k_{j,\pi,\pi'}(q,q'),$$
$$k_{j,\pi,\pi'}=\sum_T\theta_{j,T}\prod_k q_k^{|T\cap U_k|-d_j(U_k)}\prod_l {q_l'}^{|T\cap U_l'|-d_j(U_l')},$$

a polynomial with nonnegative coefficients. Its constant term is the sum of $\theta_{j,T}$ over the bases with $|T\cap U_k|=d_j(U_k)$ for $k\ge2$ and $|T\cap U_l'|=d_j(U_l')$ for $l\ge2$. As $|T\cap S|=|X^+|$, these counts determine $T\cap S=X^+$, the mark $\pi(k)$ lying in T exactly when $|T\cap U_k|-|T\cap U_{k+1}|=1$, with $U_1=S$ and $U_{|S|+1}=\varnothing$; likewise $T\cap S'=Y^+$. By (i) $X^+\sqcup Y^+$ is a basis, so the constant term is $\theta_{j,X^+\sqcup Y^+}>0$. In the same way $\Psi_j(\beta,\beta')=\prod_k q_k^{d_j^*(U_k)}\prod_l {q_l'}^{d_j^*(U_l')}\,\psi_{j,\pi,\pi'}(q,q')$, with nonnegative coefficients and the constant term $\theta_{j,X^-\sqcup Y^-}>0$. As $m_U-g(U)=\kappa_U$,

$$I_S=\sum_{\pi,\pi'}\int\prod_{k=2}^{|S|}q_k^{\kappa_{U_k}-1}\prod_{l=2}^{|S'|}{q_l'}^{\kappa_{U_l'}-1}\,h_{\pi,\pi'}(q,q')\,dq\,dq',\qquad h_{\pi,\pi'}=L_\pi^{-\kappa_S}L_{\pi'}^{-\kappa_{S'}}\prod_j k_{j,\pi,\pi'}^{-s_j}\psi_{j,\pi,\pi'}^{-t_j},$$

the product over the active tables.

Continuation. The polynomials $k_{j,\pi,\pi'}$, $\psi_{j,\pi,\pi'}$, L_π and $L_{\pi'}$ are at least their positive constant terms on the closed cube, hence positive on a neighbourhood of it; so $h_{\pi,\pi'}$ is smooth there, with every derivative continuous in the variables and the data and entire in the data, and $|h_{\pi,\pi'}|$, which is $h_{\pi,\pi'}$ at the real parts of the data, lies between positive constants on the cube, locally uniformly in the data. So the term of (π,π') converges, and is holomorphic, exactly where $\operatorname{Re}\kappa_{U_k}>0$ and $\operatorname{Re}\kappa_{U_l'}>0$ for all k,l; the tails U_k, $k\ge2$, of the orders of S are the nonempty proper subsets of S, and likewise for S'. This gives the convergence and the holomorphy of I_S. By 8.4, each term is a quotient of a holomorphic function of the data by products of the affine functions $\kappa_{U_k}+i$ and $\kappa_{U_l'}+i$, $i\in\mathbb{N}$, each a nonconstant function of the data (the coefficient of m_e, $e\in U$, being 1); so it extends meromorphically with poles only on these hyperplanes, and so does I_S. □

Theorem 16.17 (The pseudointegral off the domain). *As stated: the compound formula, with the value* 0 *on the balance wall, for every family and all complex data; the clause on targets, (i) and (ii) under the hypotheses of the reference.*

Proof. The compound formula. Let S be nonempty and proper with $c_j(S)=0$ in every active table, $S'=\mathcal{E}\setminus S$, and I_S the integral of Lemma S4, the integral of the statement. On the open convex set Ω of the data at which every proper wall has positive real part, $\operatorname{Re}\kappa_{\mathcal{E}}>0$ and $J_F=\Gamma(\kappa_S)\Gamma(\kappa_{S'})I_S$ (Lemma S4(iii)), and $J_F=\Gamma(\kappa_{\mathcal{E}})P_F$ (8.7); so $P_F={}_2\Gamma_1\left[\begin{matrix}\kappa_S,\ \kappa_{S'}\\ \kappa_{\mathcal{E}}\end{matrix}\right]I_S$ on Ω, with $\kappa_S+\kappa_{S'}=\kappa_{\mathcal{E}}$ (8.16). Both sides are meromorphic in the data, by 16.9, by Lemma S4(ii) and by 1.2, and they agree on the nonempty open set Ω; so they agree as meromorphic functions.

The value 0 *on the balance wall.* Put $G=\Gamma(\kappa_S)\Gamma(\kappa_{S'})I_S$, meromorphic in the data. The poles of $\Gamma(\kappa_S)\Gamma(\kappa_{S'})$ lie on the hyperplanes $\kappa_S=-i$ and $\kappa_{S'}=-i$, $i\in\mathbb{N}$, and those of I_S on the hyperplanes $\kappa_U=-i$ with U a nonempty proper subset of S or of S' (Lemma S4(ii)). In each case

U is a nonempty proper set of marks, so, as in the proof of 16.9, none of these hyperplanes contains the balance wall, and G restricts to a meromorphic function on the balance wall, holomorphic off a proper analytic subset of it. The function $1/\Gamma$ is entire and vanishes at 0, so $1/\Gamma(\kappa_{\mathcal{E}})$ is entire in the data and vanishes on the balance wall. Hence $P_F = G \cdot \Gamma(\kappa_{\mathcal{E}})^{-1}$ vanishes at every point of the balance wall at which G is holomorphic, and the meromorphic restriction of P_F to the balance wall is 0.

The clause on targets, (i) and (ii) are under the hypotheses of the reference, connected with real data and $s_j, t_j \geq 0$ not all zero: the reference, proof of 16.17. □

Definition 16.28 (Period datum; moves). As stated, for tables with positive rational weights.

Proof. The definition asks of the family only that its form be algebraic over $\mathbb{Q}$ and homogeneous of degree zero. The letters K_j and Ψ_j are polynomials whose coefficients are the weights, here rational; with rational exponents and masses $W\, d\alpha_{\mathbf{m}}$ is a product of rational powers of polynomials over $\mathbb{Q}$ and of the coordinates, times $d\alpha$, hence algebraic over $\mathbb{Q}$, and on the balance wall its degree is $\kappa_{\mathcal{E}} = 0$ (8.1). The walls of the faces are those of 8.5, for any weights. □

Proposition 16.32 (Sections off the balance wall). *As stated: a bunch section at every imbalance.*

Proof. The clause on a bunch section is 16.5(iii), proved above; the rest is the reference, proof of 16.32. In (ii) the walls of the chart completion at g are those of 16.5(iii) at $B = \{g\}$, $\kappa_S - \kappa_{\mathcal{E}} \mathbf{1}_S(g)$. □

Definition 16.29 (The pseudointegral over a region). As stated; the last sentence of (i) is stated for families of tables with positive rational weights, where the reference takes a list.

Proof. Let the tables have positive rational weights and the data be rational, on the balance wall. The letters K_j and Ψ_j are polynomials whose coefficients are the weights, so the form $W\, d\alpha_{\mathbf{m}}$ is algebraic over $\mathbb{Q}$ and the family has a period datum (16.28), whose moves are defined over $\mathbb{Q}$ by that definition. The three regions named in (i) are cut out by polynomial inequalities over $\mathbb{Q}$: the chart $\alpha_g = 1$ by $\alpha_e > 0$ for $e \neq g$; the simplex, in the coordinates $(u_e)_{e \neq e_0}$, by $u_e > 0$ and $1 - \sum_{e \neq e_0} u_e > 0$; a bunch section $|\alpha_B| = 1$ by these inequalities on B together with $\alpha_e > 0$ on the room.

A change of variables of 16.28 keeps this property. Let $\mathcal{R}$ lie in the open domain and be cut out there by $p_1 > 0, \ldots, p_k > 0$ with $p_i \in \mathbb{Q}[x]$, and let ϕ be birational over $\mathbb{Q}$ and carry the open domain bijectively onto the open domain. Each coordinate of ϕ^{-1} is a quotient of polynomials over $\mathbb{Q}$ whose denominator does not vanish on the open domain, where ϕ^{-1} is defined; so $p_i \circ \phi^{-1} = A_i / D_i$ with $A_i, D_i \in \mathbb{Q}[y]$, D_i a product of these denominators, and

$$\phi(\mathcal{R}) = \{y \text{ in the open domain} : \ A_i(y)\, D_i(y) > 0 \text{ for } 1 \leq i \leq k\},$$

the open domain being an orthant, cut out by the positivity of its coordinates. The region of a product of data is the product of the regions, cut out by the inequalities of the two factors in disjoint coordinates; linear combinations and boundary terms are formed on the regions already reached, as for a list. Of the family the argument of the reference uses only that its period datum and its moves are defined over $\mathbb{Q}$, which holds for positive rational weights. □

50.17 Chapter 17: the family as one Laplace transform

50.17.1 What the one-table proofs read, and what a family reads

The one-table statements read the exponent of the law of a question, $\sigma E + \delta O$ at offsets zero, through the width wd of the Newton polytope of Λ and through the convexity of E; the walls of the wedge, its slope and the volume at low strength are all values of the width. For a family the exponent is

$$X(z) = 2\langle \boldsymbol{\mu}_\perp, z\rangle - \sum_j \big(\sigma_j E_j(z) + \delta_j O_j(z)\big),$$

and what replaces the width is the wall at a tilt (Definition 17.3): on the sector of every order the exponent is minus twice the wall at the tilt less the logarithms of the sector letters (Proposition 17.4(i)), which is Theorem 8.5(ii) read in the signed coordinates. Every statement below is read off that identity, the convexity of the centred potential, and, for samples of bases, the factorization of the chance of a sample over its draws. Throughout, $n = |\mathcal{E}| \geq 2$, the data are real and on the balance wall unless said otherwise, a question is written $q = (\boldsymbol{\mu}_\perp; \boldsymbol{\sigma}, \boldsymbol{\delta})$, its data are $\big(\mathbf{m}_F(\boldsymbol{\mu}_\perp; \boldsymbol{\sigma}, \boldsymbol{\delta}); \boldsymbol{\sigma} + \boldsymbol{\delta}, \boldsymbol{\sigma} - \boldsymbol{\delta}\big)$, and $P_F(q)$ denotes its period. On the sector H_π of an order π, read in the tilts (Definition 17.3), the differences of a tilt along π are written $v_k = z_{\pi(k-1)} - z_{\pi(k)} \geq 0$, $2 \leq k \leq n$, so that $\kappa(z) = \sum_k \kappa_{U_k} v_k$; at $\alpha = e^{2z}$ the gaps of Corollary 8.6 are $2v_k$.

Lemma S5 (The walls on the balance wall)**.** *On the balance wall, for every nonempty proper S,*

$$\kappa_S = \kappa_S^{\mathbf{E}}(\boldsymbol{\sigma}) + \kappa_S^{\mathbf{O}}(\boldsymbol{\mu}_\perp, \boldsymbol{\delta}), \qquad \kappa_S^{\mathbf{E}}(\boldsymbol{\sigma}) = \sum_j \sigma_j c_j(S), \qquad \kappa_S^{\mathbf{O}}(\boldsymbol{\mu}_\perp, \boldsymbol{\delta}) = \mu_{\perp,S} - \sum_j \delta_j \varepsilon_j^\perp(S),$$

with $\varepsilon_j^\perp(S) = \varepsilon_j(S) - |S|\frac{2r_j - n}{n}$; and $\kappa_{\mathcal{E}\setminus S}^{\mathbf{E}} = \kappa_S^{\mathbf{E}}$, $\kappa_{\mathcal{E}\setminus S}^{\mathbf{O}} = -\kappa_S^{\mathbf{O}}$, so $\kappa_{\mathcal{E}\setminus S} = \kappa_S^{\mathbf{E}} - \kappa_S^{\mathbf{O}}$. In particular every wall is a linear function of the pair coordinates $(\boldsymbol{\mu}_\perp; \boldsymbol{\sigma}, \boldsymbol{\delta})$ of the question.

Proof. By Theorem 8.2(iii), $\kappa_S = \mu_S + \sum_j \big(\sigma_j c_j(S) - \delta_j \varepsilon_j(S)\big)$ and $\kappa_{\mathcal{E}} = \mu_{\mathcal{E}} - \sum_j \delta_j(2r_j - n)$. On the balance wall $\mu_{\mathcal{E}} = \sum_j \delta_j(2r_j - n)$, and $\boldsymbol{\mu} = \boldsymbol{\mu}_\perp + \frac{\mu_{\mathcal{E}}}{n}\mathbf{1}$ gives $\mu_S = \mu_{\perp,S} + \frac{|S|}{n}\sum_j \delta_j(2r_j - n)$; substituting gives the decomposition. By Theorem 7.13, $c_j(\mathcal{E} \setminus S) = c_j(S)$ and $\varepsilon_j(\mathcal{E} \setminus S) = 2r_j - n - \varepsilon_j(S)$, so $\varepsilon_j^\perp(\mathcal{E} \setminus S) = 2r_j - n - \varepsilon_j(S) - \frac{n-|S|}{n}(2r_j - n) = -\varepsilon_j^\perp(S)$, and $\mu_{\perp,\mathcal{E}\setminus S} = -\mu_{\perp,S}$ as $\boldsymbol{\mu}_\perp \in \mathbf{1}^\perp$. □

50.17.2 The exponent of a question

Definition 17.3: the claims. Let $z \in H_\pi$. A difference v_k is positive exactly when $z_{\pi(k-1)} > z_{\pi(k)}$, and then $U_k = \{e : \ z_e < z_{\pi(k-1)}\}$, a set $\{e : \ z_e < z_f\}$ with $z_f > \min_e z_e$; so the tails with a positive difference, and their differences, are read off z alone, and $\kappa(z)$ does not depend on the order π whose sector holds z. On H_π the differences are linear in z, so κ is linear there, and $\kappa(cz) = c\kappa(z)$ for $c \geq 0$. The tilt $-\mathbf{1}_S$ lies in the sectors of the orders that list $\mathcal{E} \setminus S$ first; there its only positive difference is 1, at the tail $U_k = S$, so $\kappa(-\mathbf{1}_S) = \kappa_S$. In the chart $z_{\pi(1)} = 0$ the coordinates are $z_{\pi(i)} = -(v_2 + \cdots + v_i)$, a triangular change of coordinates with determinant ± 1, so $dz = dv_2 \cdots dv_n$ on H_π; the chart does not matter (Definition 17.1). Finally $\kappa(z)$ is linear in the walls, which are linear in the question by Lemma S5.

Proposition 17.4 (The exponent of a question reads its walls; the even statistic is least at the table's gauge). *As stated, for a question with real exponents of any signs.*

Proof. (i) Write $\boldsymbol{\mu} = \mathbf{m} - \sigma\mathbf{1}$ for the offsets, so that $\boldsymbol{\mu} - \boldsymbol{\mu}_\perp \in \mathbb{R}\mathbf{1}$ and $\mu_{\mathcal{E}} = \sum_j \delta_j(2r_j - n)$ on the balance wall. The function $\tilde{X}(z) = 2\langle\boldsymbol{\mu}, z\rangle - \sum_j \big(\sigma_j E_j(z) + \delta_j O_j(z)\big)$ on $\mathbb{R}^{\mathcal{E}}$ is unchanged by $z \mapsto z + c\mathbf{1}$, since E_j is unchanged and O_j moves by $2c(2r_j - n)$ (Theorem 7.15(iii)), the move of the whole being $2c\kappa_{\mathcal{E}} = 0$ (Proposition 16.7); on $\mathbf{1}^\perp$ it is X. So X may be read at any representative of a tilt. At $\alpha = e^{2z}$, Theorem 7.15(i) gives $\sigma_j E_j + \delta_j O_j = s_j \log \Lambda_j(z) + t_j \log \Lambda_j(-z) = s_j \log K_j(\alpha) + t_j \log \Psi_j(\alpha) - (s_j + t_j)\langle\mathbf{1}, z\rangle$, and $2\langle\boldsymbol{\mu}, z\rangle + 2\sigma\langle\mathbf{1}, z\rangle = \langle\mathbf{m}, \log\alpha\rangle$, so

$$X(z) = \log\Big(\alpha^{\mathbf{m}} \prod_j K_j(\alpha)^{-s_j} \Psi_j(\alpha)^{-t_j}\Big),$$

the logarithm of the integrand of the period against the measure $d\alpha/\alpha^{\mathbf{1}}$. Take the sector coordinates of Theorem 8.5(ii) for π: $\rho = \alpha_{\pi(1)} = e^{2z_{\pi(1)}}$ and $q_k = \alpha_{\pi(k)}/\alpha_{\pi(k-1)} = e^{-2v_k}$. Since $\alpha_{\pi(i)} = \rho q_2 \cdots q_i$ and $\pi(i) \in U_k$ exactly when $k \le i$, $\alpha^{\mathbf{m}} = \rho^{m_{\mathcal{E}}} \prod_k q_k^{m_{U_k}}$; with $K_j = \rho^{r_j} \prod_k q_k^{d_j(U_k)} k_{j,\pi}(q)$ and $\Psi_j = \rho^{n-r_j} \prod_k q_k^{d_j^*(U_k)} \psi_{j,\pi}(q)$,

$$\alpha^{\mathbf{m}} \prod_j K_j^{-s_j} \Psi_j^{-t_j} = \rho^{\kappa_{\mathcal{E}}} \prod_{k=2}^{n} q_k^{\kappa_{U_k}} \prod_j k_{j,\pi}(q)^{-s_j} \psi_{j,\pi}(q)^{-t_j},$$

and $\rho^{\kappa_{\mathcal{E}}} = 1$ on the balance wall. The logarithm, with $\log q_k = -2v_k$, is the identity of (i).

On H_π the greedy basis $T^+_{j,\pi}$ has the largest monomial α^T among the bases of table j, and $T^-_{j,\pi}$ the largest $\alpha^{\mathcal{E}\setminus T}$ (Lemma 8.3); as $-\chi_T = \chi_{\mathcal{E}\setminus T}$, $h_j(z) = \langle\chi_{T^+_{j,\pi}}, z\rangle$ and $h_j(-z) = \langle\chi_{\mathcal{E}\setminus T^-_{j,\pi}}, z\rangle$, whatever the signs of the exponents. Write $z = z_{\pi(1)}\mathbf{1} - \sum_k v_k \mathbf{1}_{U_k}$; for $A \subseteq \mathcal{E}$, $\langle\chi_A, z\rangle = z_{\pi(1)}(2|A| - n) - \sum_k v_k(2|A \cap U_k| - |U_k|)$, and $|T^+_{j,\pi} \cap U_k| = d_j(U_k)$, $|U_k \setminus T^-_{j,\pi}| = d_j^*(U_k)$. So

$$\sum_j \big(s_j h_j(z) + t_j h_j(-z)\big) = 2z_{\pi(1)} \sum_j \delta_j(2r_j - n) + 2\sum_k v_k\Big(\sigma|U_k| - \sum_j \big(s_j d_j(U_k) + t_j d_j^*(U_k)\big)\Big),$$

while $2\langle\boldsymbol{\mu}, z\rangle = 2z_{\pi(1)}\mu_{\mathcal{E}} - 2\sum_k v_k \mu_{U_k}$. The difference is $2\sum_k v_k\big(m_{U_k} - \sum_j (s_j d_j(U_k) + t_j d_j^*(U_k))\big) = 2\kappa(z)$, the term in $z_{\pi(1)}$ vanishing on the balance wall; on $\mathbf{1}^\perp$, $\langle\boldsymbol{\mu}, z\rangle = \langle\boldsymbol{\mu}_\perp, z\rangle$. For $s_j, t_j \ge 0$: the support functions of P_j and P_j^* are $\frac{1}{2}(h_j(z) + \langle\mathbf{1}, z\rangle)$ and $\frac{1}{2}(h_j(-z) + \langle\mathbf{1}, z\rangle)$, support functions add over a Minkowski sum with nonnegative coefficients, and so $2\kappa(z) = 2h_{\mathcal{N}_F}(z) - 2\sigma\langle\mathbf{1}, z\rangle - 2\langle\boldsymbol{\mu}, z\rangle = 2h_{\mathcal{N}_F}(z) - 2\langle\mathbf{m}, z\rangle$, twice the support function of $\mathcal{N}_F - \mathbf{m}$, which lies in $\mathbf{1}^\perp$ and so reads tilts.

The sector letters are polynomials in q with nonnegative coefficients and the constant terms $\theta_{j,T^+_{j,\pi}}$, $\theta_{j,T^-_{j,\pi}}$, and their value at $q = \mathbf{1}$ is $K_j(\mathbf{1}) = \Psi_j(\mathbf{1})$; on $[0,1]^{n-1}$ they increase in every q_k and so lie between these (Theorem 8.5(ii)), whatever the signs of the exponents. Taking logarithms and weighting by s_j and t_j gives both bounds.

(ii) If every proper wall is positive, on H_π, $\kappa(z) = \sum_k \kappa_{U_k} v_k \ge \kappa_{\min} \sum_k v_k = \kappa_{\min}(z_{\pi(1)} - z_{\pi(n)})$, and $\max_e z_e - \min_e z_e$ vanishes on $\mathcal{T}$ only at 0. Conversely $\kappa(-\mathbf{1}_S) = \kappa_S$.

(iii) At the centre $\boldsymbol{\mu}_\perp = 0$ and $\boldsymbol{\delta} = 0$, so $X = -\sum_j \sigma_j E_j$, and the walls are $\kappa_S = \sum_j \sigma_j c_j(S)$ (Proposition 8.21(ii)). By (i), $2\kappa = \sum_j \sigma_j (h_j(z) + h_j(-z)) = \sum_j \sigma_j \operatorname{wd}_j(z)$, and $\operatorname{wd}_j(z) = \max_T\langle\chi_T, z\rangle - \min_T\langle\chi_T, z\rangle = 2\big(\max_T\langle\mathbf{1}_T, z\rangle - \min_T\langle\mathbf{1}_T, z\rangle\big)$ is twice the width of P_j in the direction z, equal to $2(r_j(S) - d_j(S)) = 2c_j(S)$ at $z = \mathbf{1}_S$ (Theorem 7.13). The bounds of (i) at $s_j = t_j = \sigma_j$ are the displayed ones. The Hessian of $\log\Lambda_j$ at z is the covariance of χ_T under $\mathbb{P}_{j,e^{2z}}$ (Theorem 7.16), so $\log\Lambda_j$ is convex, and so is $E_j(z) = \log\Lambda_j(z) + \log\Lambda_j(-z)$, which is even; hence $E_j(z) = \frac{1}{2}(E_j(z) + E_j(-z)) \ge E_j(0) = 2\log\Lambda_j(0) = 2\log K_j(\mathbf{1})$.

For $v \in \mathbf{1}^{\perp}$,

$$v^{\mathsf{T}} \nabla^2 \Big(\sum_j \sigma_j E_j \Big)(z)\, v = \sum_j \sigma_j \Big(\operatorname{Var}_{T \sim \mathbb{P}_{j,e^{2z}}} \langle \chi_T, v \rangle + \operatorname{Var}_{T \sim \mathbb{P}_{j,e^{-2z}}} \langle \chi_T, v \rangle \Big).$$

Every basis has positive chance under both laws, so the form vanishes only if $\langle \chi_T, v \rangle = 2\langle \mathbf{1}_T, v \rangle - \langle \mathbf{1}, v \rangle$ is constant over the bases of every table with $\sigma_j > 0$. Then v is constant on every molecule of the family of these tables (Lemma 7.8), and every such molecule M has $c_j(M) = 0$ in each of them, the table being the direct sum of its restrictions to the molecules (Proposition 7.9), so that $|T \cap M| = r_j(M)$ for every basis. If $v \notin \mathbb{R}\mathbf{1}$, the union S of the molecules on which v is largest is nonempty and proper with $c_j(S) = 0$ for every table with $\sigma_j > 0$: the family is not connected. So on a connected family the form is positive on $\mathcal{T} \setminus 0$ and $\sum_j \sigma_j E_j$ is strictly convex on $\mathcal{T}$. Finally $\sum_j \sigma_j \operatorname{wd}_j = 2\kappa$ is positive on $\mathcal{T} \setminus 0$ by (ii), the walls $\sum_j \sigma_j c_j(S)$ of the centre being positive exactly when the family is connected (Proposition 8.21(ii)). □

Remark. For one table at the centre of strength σ, (iii) is the statement of the reference, with $2\kappa = \sigma \operatorname{wd}$; the family statement adds (i), in which the width of one table is replaced by the wall at the tilt of any question, and (ii). The identity of (i) is the sector form of the period read pointwise: integrated against $dz = dv$ on each sector it is $P_F(q) = 2^{n-1} \sum_\pi \int_{[0,\infty)^{n-1}} e^{-2\sum_k \kappa_{U_k} v_k} h_\pi(e^{-2v})\, dv$, with $h_\pi = \prod_j k_{j,\pi}^{-s_j} \psi_{j,\pi}^{-t_j}$, which is $\sum_\pi I_\pi$ of Corollary 8.6 in the gaps $2v_k$.

50.17.3 The two ends of strength

The high end needs one fact about integrals of $e^{-\lambda f}$ with a convex exponent, for complex λ in a half-plane; it is proved here once, in the form in which the period uses it.

Lemma S6 (A convex exponent at high strength)**.** *Let f be a smooth function on a real vector space V of dimension $d \geq 1$ with Lebesgue measure dz and a norm $|\cdot|$, such that*

(a) every derivative of f of order at least one is bounded;

(b) f is convex, with a critical point $z^\star$ at which $A_0 = \nabla^2 f(z^\star)$ is positive definite;

(c) $f(z) - f(z^\star) \geq c|z| - C$ for some $c > 0$ and C.

Then $z^\star$ is the only critical point, and as $|\lambda| \to \infty$ with $\operatorname{Re}\lambda \geq \lambda_0$, for a fixed $\lambda_0 > 0$,

$$\int_V e^{-\lambda f(z)}\, dz = e^{-\lambda f(z^\star)} \Big(\frac{2\pi}{\lambda} \Big)^{\frac{d}{2}} \det(A_0)^{-\frac{1}{2}} \big(1 + O(|\lambda|^{-1}) \big),$$

the determinant in the coordinates of dz and the power principal.

Proof. Use a Euclidean norm, equivalent to the given one. *The gradient away from $z^\star$.* By convexity $\langle \nabla f(z), z - z^\star \rangle \geq f(z) - f(z^\star) \geq c|z| - C$, so $|\nabla f(z)| \geq (c|z| - C)/|z - z^\star|$, which tends to c as $|z| \to \infty$. A convex function with a positive definite Hessian at a critical point has its strict minimum there, and its critical points form the convex set of its minima, which is $\{z^\star\}$. So for every neighbourhood V_0 of $z^\star$, $|\nabla f| \geq c_0 > 0$ on $V \setminus V_0$: on a large ball by compactness, outside it by the bound.

A chart at $z^\star$. Put $A(z) = 2\int_0^1 (1-t)\, \nabla^2 f\big(z^\star + t(z - z^\star)\big)\, dt$, smooth and symmetric with $A(z^\star) = A_0$. Since $\nabla f(z^\star) = 0$, $f(z) = f(z^\star) + \frac{1}{2}\langle A(z)(z - z^\star), z - z^\star \rangle$. On a ball V_1 about $z^\star$ on which $A(z)$ is positive definite put $w(z) = A(z)^{1/2}(z - z^\star)$, the positive square root being smooth there; then $f = f(z^\star) + \frac{1}{2}|w|^2$, and $Dw(z^\star) = A_0^{1/2}$ is invertible, so w is a diffeomorphism of a smaller ball V_2 onto a neighbourhood of 0.

Near $z^\star$. Take a smooth χ with compact support in V_2 and $\chi = 1$ near $z^\star$. In the coordinates w, $\int \chi e^{-\lambda f} dz = e^{-\lambda f(z^\star)} \int_{\mathbb{R}^d} e^{-\lambda |w|^2/2} g(w)\, dw$, with g smooth of compact support and $g(0) = |\det Dw(z^\star)|^{-1} = \det(A_0)^{-1/2}$. For $\operatorname{Re}\lambda > 0$ and $\xi \in \mathbb{R}^d$, $\int e^{-\lambda|w|^2/2 + i\langle \xi, w\rangle} dw = (2\pi/\lambda)^{d/2} e^{-|\xi|^2/(2\lambda)}$: both sides are holomorphic in λ on the half-plane and agree for $\lambda > 0$, completing the square in each coordinate. Writing $g(w) = (2\pi)^{-d} \int \hat g(\xi) e^{i\langle \xi, w\rangle} d\xi$ with $\hat g$ rapidly decreasing,

$$\int e^{-\lambda|w|^2/2} g(w)\, dw = \Big(\frac{2\pi}{\lambda}\Big)^{\frac{d}{2}} (2\pi)^{-d} \int \hat g(\xi)\, e^{-|\xi|^2/(2\lambda)}\, d\xi = \Big(\frac{2\pi}{\lambda}\Big)^{\frac{d}{2}} \big(g(0) + \varrho(\lambda)\big),$$

and since $\operatorname{Re}(1/\lambda) \geq 0$ and $|e^{-x} - 1| \leq |x|$ for $\operatorname{Re} x \geq 0$, $|\varrho(\lambda)| \leq (2|\lambda|)^{-1} (2\pi)^{-d} \int |\xi|^2 |\hat g(\xi)|\, d\xi$.

Away from $z^\star$. On the support of $1 - \chi$, $|\nabla f| \geq c_0$. The operator $L = -\lambda^{-1} |\nabla f|^{-2} \langle \nabla f, \nabla \rangle$ has $L e^{-\lambda f} = e^{-\lambda f}$, and its transpose is $L^{\mathsf t} \varphi = \lambda^{-1} \operatorname{div}\big(\varphi\, |\nabla f|^{-2} \nabla f\big)$. Integrating by parts N times, $\int (1-\chi) e^{-\lambda f} dz = \int e^{-\lambda f} (L^{\mathsf t})^N (1-\chi)\, dz$, with no boundary terms: $1 - \chi$ vanishes near $z^\star$, and on large spheres $|e^{-\lambda f}| = e^{-\operatorname{Re}\lambda f}$ decays exponentially by (c) while the coefficients stay bounded. Now $(L^{\mathsf t})^N (1-\chi) = \lambda^{-N} G_N$ with G_N a polynomial in the derivatives of χ, in those of f of orders 1 to $N+1$ and in $|\nabla f|^{-2}$, bounded by (a) and $|\nabla f| \geq c_0$. Since $f \geq f(z^\star)$ and $\operatorname{Re}\lambda \geq \lambda_0$,

$$\Big| \int (1-\chi) e^{-\lambda f} dz \Big| \leq |\lambda|^{-N} \sup |G_N|\; e^{-\operatorname{Re}\lambda\, f(z^\star)} \int_V e^{-\lambda_0 (f - f(z^\star))} dz,$$

the last integral finite by (c). With $N > \frac{d}{2} + 1$ this is $O(|\lambda|^{-1})$ times the modulus $(2\pi/|\lambda|)^{d/2} e^{-\operatorname{Re}\lambda f(z^\star)} \det(A_0)^{-1/2}$ of the leading term, and the two parts add to the statement. (On the real half-line this is Laplace's method, along the imaginary direction stationary phase, and w is the Morse chart.) □

Theorem 17.5 (The two ends of strength). *As stated.*

Proof. The walls and the exponents of λq are λ times those of q (Lemma S5), so its walls $\lambda \kappa_S$ have positive real parts for $\operatorname{Re}\lambda > 0$. At such data the period is the convergent integral of Theorem 8.7, the powers of the positive letters principal, and the change of variables of Definition 17.1, which uses only $K_j(e^{2z}) = e^{\langle \mathbf{1}, z\rangle} \Lambda_j(z)$ and $\Psi_j(e^{2z}) = e^{\langle \mathbf{1}, z\rangle} \Lambda_j(-z)$, gives $P_F(\lambda q) = 2^{n-1} \int_{\mathcal T} e^{\lambda X(z)} dz$, absolutely convergent as $|e^{\lambda X}| = e^{\operatorname{Re}\lambda\, X}$; here X is the exponent of q, and the exponent of λq is λX, the exponent being linear in the question.

(i) By Proposition 17.4(i) and $dz = dv$ on each sector, with $h_\pi = \prod_j k_{j,\pi}^{-s_j} \psi_{j,\pi}^{-t_j}$,

$$P_F(\lambda q) = 2^{n-1} \sum_\pi \int_{[0,\infty)^{n-1}} e^{-2\lambda \sum_k \kappa_{U_k} v_k}\, h_\pi(e^{-2v})^\lambda\, dv,$$

and with $v = w/\lambda$,

$$\lambda^{n-1} P_F(\lambda q) = 2^{n-1} \sum_\pi \int_{[0,\infty)^{n-1}} e^{-2\sum_k \kappa_{U_k} w_k}\, h_\pi(e^{-2w/\lambda})^\lambda\, dw.$$

On the cube $|\log h_\pi| \leq C$ (Proposition 17.4(i)), so for $0 < \lambda \leq 1$ the integrand lies between $e^{\mp C} e^{-2\sum_k \kappa_{U_k} w_k}$, whose integral is $\prod_k (2\kappa_{U_k})^{-1}$; it tends to $e^{-2\sum_k \kappa_{U_k} w_k}$, and by domination $\lambda^{n-1} P_F(\lambda q) \to 2^{n-1} \sum_\pi \prod_k (2\kappa_{U_k})^{-1} = \sum_\pi \prod_k \kappa_{U_k}^{-1}$. For the next order, $|h^\lambda - 1 - \lambda \log h| \leq \frac{1}{2} \lambda^2 C^2 e^{\lambda C}$, and for w in the open orthant $e^{-2w/\lambda} \to 0$, so $\log h_\pi(e^{-2w/\lambda}) \to \log h_\pi(0)$, boundedly; hence

$$\lambda^{-1} \Big(\lambda^{n-1} P_F(\lambda q) - \sum_\pi \prod_k \kappa_{U_k}^{-1} \Big) \to \sum_\pi \prod_k \kappa_{U_k}^{-1} \log h_\pi(0),$$

and $h_\pi(0) = \prod_j \theta_{j,T^+_{j,\pi}}^{-s_j}\theta_{j,T^-_{j,\pi}}^{-t_j}$ is the sector integrand at $q = 0$, so that $\log h_\pi(0) = -\sum_j \big(s_j \log\theta_{j,T^+_{j,\pi}} + t_j \log\theta_{j,T^-_{j,\pi}}\big)$, the coefficient stated. Finally κ is positively homogeneous of degree one and positive on $\mathcal{T}\setminus 0$ (Proposition 17.4(ii)), so $\operatorname{vol}\{\kappa\le r\} = r^{n-1}\operatorname{vol}\{\kappa\le 1\}$ and

$$2^{n-1}\int_{\mathcal{T}} e^{-2\kappa(z)}dz = 2^{n-1}\operatorname{vol}\{\kappa\le 1\}\,(n-1)\int_0^\infty e^{-2r}r^{n-2}dr = (n-1)!\operatorname{vol}\{\kappa\le 1\},$$

while on the sectors the same integral is $2^{n-1}\sum_\pi\prod_k(2\kappa_{U_k})^{-1}$. (For $s_j,t_j\ge 0$, $\{\kappa\le 1\}$ is the polar of $\mathcal{N}_F-\mathbf{m}$ in $\mathbf{1}^\perp$.)

(ii) Let $s_j,t_j\ge 0$ and $f=-X$ on $\mathcal{T}$, of dimension $n-1$ with the measure dz. The hypotheses of Lemma S6 hold. (a) Every derivative of $\log\Lambda_j$ of order $k\ge 1$ is a joint cumulant of order k of $\chi_T\in\{\pm1\}^{\mathcal{E}}$ under $\mathbb{P}_{j,e^{2z}}$ (Theorem 7.16), bounded by a constant depending on k alone, and $f=\sum_j\big(s_j\log\Lambda_j(z)+t_j\log\Lambda_j(-z)\big)-2\langle\boldsymbol{\mu}_\perp,z\rangle$. (b) $v^{\mathsf T}\nabla^2 f(z)v=\sum_j\big(s_j\operatorname{Var}_{\mathbb{P}_{j,e^{2z}}}\langle\chi_T,v\rangle+t_j\operatorname{Var}_{\mathbb{P}_{j,e^{-2z}}}\langle\chi_T,v\rangle\big)$; a question with $s_j,t_j\ge 0$ inside its walls is on a connected family, as $\kappa_S+\kappa_{\mathcal{E}\setminus S}=2\sum_j\sigma_j c_j(S)>0$ (Lemma S5) puts some active table of positive width on every S, and the argument of Proposition 17.4(iii) makes the form positive definite on $\mathcal{T}$ at every z; so f is strictly convex. (c) $f\ge 2\kappa-C\ge 2\kappa_{\min}(\max_e z_e-\min_e z_e)-C$ by Proposition 17.4(i)–(ii), and $\max_e z_e-\min_e z_e$ is a norm on $\mathcal{T}$. A strictly convex f with (c) attains its minimum at one point $z^\star$, its only critical point. By Theorem 7.16, $\nabla\log\Lambda_j(z)=2R_j(\alpha)-\mathbf{1}$ and $\nabla[\log\Lambda_j(-z)]=\mathbf{1}-2R_j(\alpha^{-1})=2R_j^*(\alpha)-\mathbf{1}$ at $\alpha=e^{2z}$, so the derivative of f along $v\in\mathbf{1}^\perp$ is $2\langle\mathbf{u}(\alpha)-\mathbf{m},v\rangle$, $\mathbf{u}=\sum_j(s_jR_j+t_jR_j^*)$ the usage, $\mathbf{m}-\sigma\mathbf{1}-\boldsymbol{\mu}_\perp$ being a multiple of $\mathbf{1}$. It vanishes for every v exactly when $\mathbf{u}(\alpha)-\mathbf{m}\in\mathbb{R}\mathbf{1}$, that is $\mathbf{u}(\alpha)=\mathbf{m}$, the two having the total $\sum_j(s_jr_j+t_jr_j^*)$ on the balance wall; and $\mathbf{m}$ is the target of q there, so $z^\star$ is its native gauge (Definition 8.17). The usage and the masses of λq are λ times those of q, so $z^\star$ is the native gauge of every λq, $\lambda>0$. Lemma S6 with $d=n-1$ gives the expansion, the determinant taken on a chart $z_g=0$, that is of the Hessian of the invariant form $\tilde X$ of the proof of Proposition 17.4 with the row and the column of g deleted. With $y=2z$, $\Phi(y)=\sigma\langle\mathbf{1},y\rangle+\Phi^\circ(z)$ (Theorem 8.19), so $\partial_{z_e}\partial_{z_f}(-\tilde X)=\partial_{z_e}\partial_{z_f}\Phi^\circ=4\partial_{y_e}\partial_{y_f}\Phi$, rung two of the still of the realization $\big((s_j,t_j)_j;e^{2z^\star}\big)$ of the active tables (Definition 9.4). At the centre $f=\sum_j\sigma_jE_j$ is even and strictly convex, so $z^\star=0$, $f(0)=2\sum_j\sigma_j\log K_j(\mathbf{1})$, and $\nabla^2 f(0)=\sum_j\sigma_j\cdot 2\operatorname{Cov}_{\mathbb{P}_{j,\mathbf{1}}}(\chi_T)=8\sum_j\sigma_j\big(\kappa_{j,\mathbf{1}}(X_e,X_f)\big)_{e,f}$, as $\chi_T=2X-\mathbf{1}$, read on the chart $z_g=0$ with the row and the column of g deleted. □

Remark. At one table and the centre of strength one, $\kappa=\frac12\,\mathrm{wd}$ and $(n-1)!\operatorname{vol}\{\kappa\le 1\}=2^{n-1}(n-1)!\operatorname{vol}\{\mathrm{wd}\le 1\}$, the reference's low end; its high end is (ii) at offsets zero. Divided by the same limit for the list $\binom{\mathcal{E}}{1}$ at a full basis lean, whose walls are the masses, (i) is the limit of Proposition 49.14: there $\Gamma_{\binom{n}{1}}\begin{bmatrix}\lambda\boldsymbol{\tau}\\ \lambda\tau_{\mathcal{E}}\end{bmatrix}$ has $\lambda^{n-1}\Gamma_{\binom{n}{1}}\begin{bmatrix}\lambda\boldsymbol{\tau}\\ \lambda\tau_{\mathcal{E}}\end{bmatrix}\to\tau_{\mathcal{E}}/\prod_e\tau_e=\sum_\pi\prod_k\tau_{U_k}^{-1}$. In (ii) the real ray is Proposition 18.9 written in the signed coordinates; what the lemma adds is the whole half-plane, uniformly.

50.17.4 How far a question can lean, and the tails

Proposition 17.7 (How far a question can lean; the values of the statistics). *As stated.*

Proof. The decomposition of the walls is Lemma S5. Every proper wall is positive exactly when, for every S, $\kappa_S^{\mathbf{E}}+\kappa_S^{\mathbf{O}}>0$ and $\kappa_S^{\mathbf{E}}-\kappa_S^{\mathbf{O}}>0$, that is $|\kappa_S^{\mathbf{O}}|<\kappa_S^{\mathbf{E}}$. The fold of Theorem 16.18 sends the pair coordinates $(\boldsymbol{\mu}_\perp;\boldsymbol{\sigma},\boldsymbol{\delta})$ to $(-\boldsymbol{\mu}_\perp;\boldsymbol{\sigma},-\boldsymbol{\delta})$, negating the offsets and the leans and keeping

the strengths (Definition 9.1); so it negates $\kappa_S^{\mathbf{O}}$ and swaps κ_S with $\kappa_{\mathcal{E}\setminus S}$. When every $\kappa_S^{\mathbf{E}}(\boldsymbol{\sigma})$ is positive the conditions read $\kappa_S^{\mathbf{E}}/|\kappa_S^{\mathbf{O}}| > 1$ wherever $\kappa_S^{\mathbf{O}} \neq 0$, that is $\ell^*_{\boldsymbol{\sigma}}(\boldsymbol{\mu}_\perp, \boldsymbol{\delta}) > 1$: finitely many strict linear inequalities in the odd part, each with its negative, an open convex polyhedron symmetric under the fold. It is bounded exactly when the linear map $(c, \mathbf{b}) \mapsto (\kappa_S^{\mathbf{O}}(c, \mathbf{b}))_S$ is injective: then it lies in the preimage of a bounded box, and otherwise a line through 0 in the kernel lies in it. The homogeneities and the evenness in $(c, \mathbf{b})$ are read off the definition. For one connected table at offsets zero, $\kappa_S^{\mathbf{E}} = \sigma c(S)$ and $\kappa_S^{\mathbf{O}} = -\delta\varepsilon^\perp(S)$, so the conditions are $\sigma > 0$ and $|\delta| < \sigma \min c(S)/|\varepsilon^\perp(S)| = \ell_1^*(0,1)\,\sigma$.

(i) The exponent is linear in the question, so with $q' = (c; \boldsymbol{\sigma} + \mathbf{a}, \mathbf{b})$ and the exponent $X_{q'}$ of q', the expectation is $2^{n-1} P_F(\sigma\mathbf{1}; \boldsymbol{\sigma}, \boldsymbol{\sigma})^{-1} \int_{\mathcal{T}} e^{X_{q'}(z)} dz$, an integral of a positive function. By Proposition 17.4(i), whose identity holds at every real exponents, $e^{X_{q'}}$ lies between constant multiples of $e^{-2\kappa'(z)}$, κ' the wall at the tilt of q', and $\int_{H_\pi} e^{-2\kappa'(z)} dz = \int_{[0,\infty)^{n-1}} e^{-2\sum_k \kappa_{U_k}(q')v_k} dv$ is finite exactly when every $\kappa_{U_k}(q')$ is positive. Every nonempty proper S is a tail of some order, so the expectation is finite exactly when every proper wall of q' is positive, and it is then $P_F(q')/P_F(\sigma\mathbf{1}; \boldsymbol{\sigma}, \boldsymbol{\sigma})$ by Definition 17.1. The walls of q' are $\kappa_S^{\mathbf{E}}(\boldsymbol{\sigma} + \mathbf{a}) \pm \kappa_S^{\mathbf{O}}(c, \mathbf{b})$; at $\mathbf{a} = 0$ their positivity is $\ell^*_{\boldsymbol{\sigma}}(c, \mathbf{b}) > 1$.

(ii) With $|\delta_j| \le \sigma_j$ the exponents are nonnegative, and by the proof of Theorem 17.5(ii) $-X$ is strictly convex on $\mathcal{T}$ with its least value at the native gauge $z^\star$, at which alone it is attained. $-X(z)$ is the value of the linear form $-2\langle \boldsymbol{\mu}_\perp, x\rangle + \sum_j (\sigma_j y_j + \delta_j w_j)$ at the point $(z; E_j(z), O_j(z))_j$, and z is a coordinate of that point, so the least value of the form on the set of values of the statistics is taken at $\big(z^\star; E_j(z^\star), O_j(z^\star)\big)_j$ and only there. At the centre $z^\star = 0$ (Proposition 17.4(iii)), $E_j(0) = 2\log K_j(\mathbf{1})$ and $O_j(0) = 0$. □

Proposition 17.8 (The tails of the statistics are read at the walls). *As stated.*

Proof. By Lemma S5 the walls are linear in the pair coordinates, and for the direction v of pair coordinates $(c; \mathbf{a}, \mathbf{b})$, $\kappa_S(v) = \kappa_S^{\mathbf{E}}(\mathbf{a}) + \kappa_S^{\mathbf{O}}(c, \mathbf{b})$, the offset direction c entering through $c_S = \sum_{e\in S} c_e$. With $X_v(z) = 2\langle c, z\rangle - \sum_j (a_j E_j(z) + b_j O_j(z))$, $Y = X_v(Z)$ and $X_q + \lambda X_v = X_{q+\lambda v}$, so for real $\lambda \ge 0$, $\mathbb{E}[e^{\lambda Y}] = 2^{n-1} P_F(q)^{-1} \int_{\mathcal{T}} e^{X_{q+\lambda v}} dz$, finite, by the argument of Proposition 17.7(i), exactly when every $\kappa_S(q) + \lambda\kappa_S(v)$ is positive, that is for $\lambda < \lambda^*$, and then the ratio of the periods.

Upper bound. For $0 < \lambda < \lambda^*$, $\mathbb{P}(Y > x) \le e^{-\lambda x}\mathbb{E}[e^{\lambda Y}]$, so $\limsup_x x^{-1}\log \mathbb{P}(Y > x) \le -\lambda$ for every $\lambda < \lambda^*$.

Lower bound. Let $\lambda^* < \infty$, let S^* attain it, and let π list $\mathcal{E}\setminus S^*$ first, so that $S^* = U_{k^*}$ is a tail of π. Write $\kappa_q(z)$ and $\kappa_v(z) = \sum_k \kappa_{U_k}(v)\big(z_{\pi(k-1)} - z_{\pi(k)}\big)$ for the walls at the tilt of q and of v, the latter read as balanced data with the exponents $(\mathbf{a} + \mathbf{b}, \mathbf{a} - \mathbf{b})$. By Proposition 17.4(i), whose identity holds at any balanced real data, $|X_q + 2\kappa_q| \le C_q$ and $|X_v + 2\kappa_v| \le C_v$ on $\mathcal{T}$. For $\varepsilon > 0$ put $a_x = (1+\varepsilon)x/(-2\kappa_{S^*}(v))$ and let $A_x \subset H_\pi$ be the set of the tilts whose difference along π at the tail S^* lies in $[a_x, a_x + 1]$ and whose other differences lie in $[0, 1]$, of dz-volume 1. On A_x, as $\kappa_{S^*}(v) < 0$,

$$Y \ge -2\kappa_v(z) - C_v \ge (1+\varepsilon)x - 2\sum_k |\kappa_{U_k}(v)| - C_v > x \quad \text{for large } x,$$

$$X_q \ge -2\kappa_q(z) - C_q \ge -2\kappa_{S^*}(q)(a_x + 1) - 2\sum_k |\kappa_{U_k}(q)| - C_q = -(1+\varepsilon)\lambda^* x - C',$$

since $2\kappa_{S^*}(q)a_x = (1+\varepsilon)\lambda^* x$. So $\mathbb{P}(Y > x) \ge 2^{n-1} P_F(q)^{-1} e^{-(1+\varepsilon)\lambda^* x - C'}$ for large x, $\liminf_x x^{-1}\log \mathbb{P}(Y > x) \ge -(1+\varepsilon)\lambda^*$ for every $\varepsilon > 0$, and with the upper bound the limit is $-\lambda^*$.

If $\lambda^* = \infty$, every $\kappa_S(v) \ge 0$, so $\kappa_v \ge 0$ on every sector and $Y \le C_v$.

At the centre of strengths $\boldsymbol{\sigma}$ and the direction of pair coordinates $(c;\mathbf{0},\mathbf{b})$, $\kappa_S(q)=\kappa_S^{\mathbf{E}}(\boldsymbol{\sigma})$ and $\kappa_S(v)=\kappa_S^{\mathbf{O}}(c,\mathbf{b})$. The first is unchanged and the second negated by $S\mapsto\mathcal{E}\setminus S$, so the sets on which $\kappa_S(v)<0$ are the complements of those on which it is positive, and $\lambda^*=\min_S \kappa_S^{\mathbf{E}}/|\kappa_S^{\mathbf{O}}|=\ell^*_{\boldsymbol{\sigma}}(c,\mathbf{b})$, for Y and for $-Y$ alike. □

Remark. The one-table rate of both tails of $O(Z)$ at the centre of strength σ_0 is $\ell^*_{\sigma_0}(0,1)=\sigma_0\,\ell^*_1(0,1)$. The same proposition, applied to the family with the list $\binom{\mathcal{E}}{1}$ added, gives the tails of the Grey law (Proposition 49.12(iii), proved in Section 50.48.3).

50.18 Chapter 18: the Breta law and the port on the balance wall

Proposition 18.3 (Scale and shapes along a bunch). *As stated: off the balance wall and at complex exponents, the scale integral then carrying the appended list* $\binom{\mathcal{E}}{1}$.

Proof. The display. The masses are positive and every proper wall has positive real part, so $P_F(\mathbf{m};\mathbf{s},\mathbf{t})=\int_{\Delta_\mathcal{E}} u^{\mathbf{m}-\mathbf{1}}W(u)\,d\omega_\mathcal{E}(u)$ converges (8.7). By 3.12 with the blocks B and R, $u=(w_Bv_B,w_Rv_R)$ with $(w_B,w_R)\in\Delta_{\{B,R\}}$, $v_B\in\Delta_B$ and $v_R\in\Delta_R$, and

$$u^{\mathbf{m}-\mathbf{1}}d\omega_\mathcal{E}=w_B^{m_B-1}w_R^{m_R-1}dw_B\cdot v_B^{\mathbf{m}|_B-\mathbf{1}}d\omega_B\cdot v_R^{\mathbf{m}|_R-\mathbf{1}}d\omega_R.$$

With $x=w_B/w_R\in(0,\infty)$, $w_B=x/(1+x)$, $w_R=1/(1+x)$ and $dw_B=(1+x)^{-2}dx$, so $w_B^{m_B-1}w_R^{m_R-1}dw_B=x^{m_B-1}(1+x)^{-m_\mathcal{E}}dx$. The word W is homogeneous of degree $\kappa_\mathcal{E}-m_\mathcal{E}$ (8.1), so $W(w_Bv_B,w_Rv_R)=w_R^{\kappa_\mathcal{E}-m_\mathcal{E}}W(xv_B,v_R)=(1+x)^{m_\mathcal{E}-\kappa_\mathcal{E}}W(xv_B,v_R)$, and the powers of $1+x$ collect to $(1+x)^{-\kappa_\mathcal{E}}$. By Tonelli on the modulus, which is the same integrand at the real parts of the exponents, and Fubini,

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t})=\int_{\Delta_B}\int_{\Delta_R} v_B^{\mathbf{m}|_B-\mathbf{1}}v_R^{\mathbf{m}|_R-\mathbf{1}}\int_0^\infty x^{m_B-1}(1+x)^{-\kappa_\mathcal{E}}W(xv_B,v_R)\,dx\,d\omega_R(v_R)\,d\omega_B(v_B).$$

The densities of $\mathrm{Dir}_{\mathbf{m}|_B}$ and $\mathrm{Dir}_{\mathbf{m}|_R}$ are $v_B^{\mathbf{m}|_B-\mathbf{1}}/\Gamma_{\binom{|B|}{1}\binom{\mathbf{m}|_B}{m_B}}$ and $v_R^{\mathbf{m}|_R-\mathbf{1}}/\Gamma_{\binom{|R|}{1}\binom{\mathbf{m}|_R}{m_R}}$ (3.10), which gives the display. At (xU_B',U_R') the letter $|\alpha|$ of the list $\binom{\mathcal{E}}{1}$ is $x|U_B'|+|U_R'|=1+x$, so the inner integral is the scale integral (15.3) of the family with that table appended at the exponents $(\kappa_\mathcal{E},0)$ (16.3). On the balance wall the factor $(1+x)^{-\kappa_\mathcal{E}}$ is 1, the inner integral is $\mathrm{Sc}_B(U_B',U_R';\mathbf{m};\mathbf{s},\mathbf{t})$, and the double integral above is 16.6 at $h=|\alpha_R|$.

The conditional density. For real data with every proper wall positive the same computation, which needs no sign of the masses, shows that under $\mathrm{Breta}^\circ(F;\mathbf{m};\mathbf{s},\mathbf{t})$ the variables $\rho=|U_B|/|U_R|$, V_B and V_R have the joint density

$$\rho^{m_B-1}(1+\rho)^{-\kappa_\mathcal{E}}W(\rho V_B,V_R)\,V_B^{\mathbf{m}|_B-\mathbf{1}}V_R^{\mathbf{m}|_R-\mathbf{1}}/P_F(\mathbf{m};\mathbf{s},\mathbf{t})$$

against $d\rho\,d\omega_B\,d\omega_R$. Given (V_B,V_R), the density of ρ is proportional to $\rho^{m_B-1}(1+\rho)^{-\kappa_\mathcal{E}}W(\rho V_B,V_R)$. On the balance wall this is the reference, proof of 18.3. □

Corollary 18.7 (Conjugacy for the continued period). *As stated.*

Proof. Let Ω be the set of the data at which every nonempty proper wall has positive real part, open and convex, and not empty: at $\mathbf{s}=\mathbf{t}=\mathbf{0}$ the walls are $\kappa_S=m_S$. Adding $\mathbf{1}_T$ to the masses and $\mathbf{e}_j$ to $\mathbf{s}$ adds r_j to $m_\mathcal{E}$ and to $\sum_i(s_ir_i+t_ir_i^*)$, so it keeps the imbalance and maps the balance

wall into itself, and it adds $|T\cap S|-d_j(S)\ge 0$ to the wall κ_S (8.1), so it maps Ω into Ω; adding $\mathbf{1}_{\mathcal{E}\setminus T'}$ to the masses and $\mathbf{e}_j$ to $\mathbf{t}$ does the same, adding $|S\setminus T'|-d_j^*(S)\ge 0$ to κ_S. At data in Ω the three periods converge absolutely as integrals over $\Delta_{\mathcal{E}}$ (8.7). On $\Delta_{\mathcal{E}}$, $K_j(u)=\sum_T \theta_{j,T}u^{\mathbf{1}_T}$ and $\Psi_j(u)=\sum_{T'}\theta_{j,T'}u^{\mathbf{1}_{\mathcal{E}\setminus T'}}$ (7.1), so

$$u^{\mathbf{m}-\mathbf{1}}\prod_i K_i(u)^{-s_i}\Psi_i(u)^{-t_i}=\sum_T \theta_{j,T}\,u^{\mathbf{m}+\mathbf{1}_T-\mathbf{1}}K_j(u)^{-s_j-1}\prod_{i\ne j}K_i(u)^{-s_i}\prod_i\Psi_i(u)^{-t_i},$$

the powers of the positive letters being principal, and integrating term by term gives the first identity on Ω; the second is the same with Ψ_j. By 16.9 the three sides are meromorphic in the masses and the exponents, the shifted ones being P_F composed with translations, and they agree on the nonempty open set Ω, so they agree as meromorphic functions. Their restrictions to the balance wall, meromorphic by 16.9 and mapped into themselves by the translations, then agree as well. □

Lemma S7. *Let G be a convex function of class C^2 on $\mathbb{R}^d$ with $G(0)=0$, $\nabla G(0)=0$ and $\nabla^2G(0)$ positive definite, and let b be a measurable function on $\mathbb{R}^d$, continuous at 0, with $|b(y)|\le e^{c_0(1+|y|)}$ for a constant $c_0\ge 0$. Then $\int_{\mathbb{R}^d}|b|e^{-\lambda G}dy<\infty$ for every large λ, and for every bounded continuous function H on $\mathbb{R}^d$*

$$\lim_{\lambda\to+\infty}\lambda^{d/2}\int_{\mathbb{R}^d}b(y)H(\sqrt{\lambda}\,y)e^{-\lambda G(y)}dy=b(0)\int_{\mathbb{R}^d}H(x)e^{-\frac12\langle x,\nabla^2G(0)x\rangle}dx.$$

At $H=1$ the right side is $b(0)(2\pi)^{d/2}\det\big(\nabla^2G(0)\big)^{-1/2}$.

Proof. Let $\epsilon>0$ be the least eigenvalue of $\nabla^2G(0)$. By Taylor's formula $G(y)=\frac12\langle y,\nabla^2G(0)y\rangle+o(|y|^2)$; choose $\delta>0$ with $G(y)\ge\frac14\langle y,\nabla^2G(0)y\rangle\ge\frac{\epsilon}{4}|y|^2$ and $|b(y)|\le|b(0)|+1$ for $|y|\le\delta$.

Linear growth. For $|y|\ge\delta$ put $t=\delta/|y|\in(0,1]$. Convexity and $G(0)=0$ give $G(ty)\le tG(y)$, so $G(y)\ge t^{-1}G(ty)\ge\frac{|y|}{\delta}\cdot\frac{\epsilon}{4}\delta^2=\gamma|y|$, with $\gamma=\frac{\epsilon\delta}{4}$.

The outer part. For $\lambda\gamma\ge 2c_0$ and $|y|\ge\delta$, $|b(y)|e^{-\lambda G(y)}\le e^{c_0-\frac14\lambda\gamma|y|}\le e^{c_0-\frac14\lambda\gamma\delta}e^{-\frac14\lambda\gamma|y|}$. So $\int_{|y|\ge\delta}|b|e^{-\lambda G}dy\le e^{c_0-\frac14\lambda\gamma\delta}\big(\frac{4}{\lambda\gamma}\big)^d\int_{\mathbb{R}^d}e^{-|x|}dx$, and $\lambda^{d/2}$ times it tends to 0. With the bound on $|y|\le\delta$, the integral of $|b|e^{-\lambda G}$ is finite.

The inner part. With $y=x/\sqrt{\lambda}$,

$$\lambda^{d/2}\int_{|y|<\delta}b(y)H(\sqrt{\lambda}\,y)e^{-\lambda G(y)}dy=\int_{\mathbb{R}^d}\mathbf{1}\big[|x|<\delta\sqrt{\lambda}\big]\,b(x/\sqrt{\lambda})H(x)e^{-\lambda G(x/\sqrt{\lambda})}dx.$$

As $\lambda\to\infty$ the integrand tends to $b(0)H(x)e^{-\frac12\langle x,\nabla^2G(0)x\rangle}$ at every x, by the continuity of b at 0 and $\lambda G(x/\sqrt{\lambda})\to\frac12\langle x,\nabla^2G(0)x\rangle$, and it is bounded by $(|b(0)|+1)\sup|H|\,e^{-\epsilon|x|^2/4}$, which is integrable. Dominated convergence gives the limit. At $H=1$, $\int e^{-\frac12\langle x,Ax\rangle}dx=(2\pi)^{d/2}(\det A)^{-1/2}$ for positive definite A. □

Proposition 18.9 (The period along a ray of data). *As stated: a base point of complex data on the balance wall added to the scaled data.*

Proof. Write $\mathbf{d}_\lambda=(\mathbf{m}_0+\lambda\boldsymbol{\tau};\mathbf{s}_0+\lambda\mathbf{s},\mathbf{t}_0+\lambda\mathbf{t})$, and in this proof $G(y)=\Phi(y)-\langle\boldsymbol{\tau},y\rangle$, Φ the potential at $(\mathbf{s},\mathbf{t})$.

The data. The walls and the imbalance are affine in the data with real coefficients. At $(\boldsymbol{\tau};\mathbf{s},\mathbf{t})$, real data with $\boldsymbol{\tau}>0$, $s_j,t_j\ge 0$ not all zero and a native gauge on a connected family, every proper

wall is positive (8.19(iii)), and both $(\boldsymbol{\tau};\mathbf{s},\mathbf{t})$ and $(\mathbf{m}_0;\mathbf{s}_0,\mathbf{t}_0)$ lie on the balance wall. So $\kappa_{\mathcal{E}}(\mathbf{d}_\lambda)=0$, and $\operatorname{Re}\kappa_S(\mathbf{d}_\lambda)=\operatorname{Re}\kappa_S(\mathbf{m}_0;\mathbf{s}_0,\mathbf{t}_0)+\lambda\kappa_S(\boldsymbol{\tau};\mathbf{s},\mathbf{t})\to+\infty$ for every nonempty proper S: for λ large every proper wall of $\mathbf{d}_\lambda$ has positive real part.

The chart integral. For such λ, $P_F(\mathbf{d}_\lambda)$ is the integral over the chart $\alpha_g=1$ (16.2). In $y=\log\alpha$, $y_g=0$, the measure is $\alpha^{\mathbf{m}-\mathbf{1}}d\alpha_{\mathcal{E}-g}=e^{\langle\mathbf{m},y\rangle}dy_{\mathcal{E}-g}$, and the family word at the exponents $(\mathbf{s}_0+\lambda\mathbf{s},\mathbf{t}_0+\lambda\mathbf{t})$ is $W_0(e^y)e^{-\lambda\Phi(y)}$ (8.18). So

$$P_F(\mathbf{d}_\lambda)=\int_{\{y_g=0\}}b(y)\,e^{-\lambda G(y)}\,dy_{\mathcal{E}-g},\qquad b(y)=e^{\langle\mathbf{m}_0,y\rangle}W_0(e^y).$$

The minimum. Φ is convex (8.19(ii)), and $\nabla G(y)=\nabla\Phi(y)-\boldsymbol{\tau}$ is the usage at e^y less the target, which vanishes at $y^\star=\log\alpha^\star$ (8.19(i)); normalize $\alpha^\star_g=1$, so that $y^\star$ lies on the chart. For $v\in\mathbb{R}^{\mathcal{E}}$ and $\alpha=e^y$,

$$\langle v,\nabla^2\Phi(y)v\rangle=\sum_j\Big(s_j\operatorname{Var}_{T\sim\mathbb{P}_{j,\alpha}}\langle v,\mathbf{1}_T\rangle+t_j\operatorname{Var}_{T\sim\mathbb{P}^*_{j,\alpha}}\langle v,\mathbf{1}_T\rangle\Big),$$

since $\partial_c^2\log K_j(e^{y+cv})$ at $c=0$ is the variance of $\langle v,\mathbf{1}_T\rangle$ under $\mathbb{P}_{j,\alpha}(T)=\theta_{j,T}\alpha^T/K_j(\alpha)$ (7.16), and likewise for Ψ_j under $\mathbb{P}^*_{j,\alpha}$, with $\langle v,\mathbf{1}_{\mathcal{E}\setminus T}\rangle=\langle v,\mathbf{1}\rangle-\langle v,\mathbf{1}_T\rangle$. Both laws charge every basis. So if $\langle v,\nabla^2\Phi(y)v\rangle=0$, then $\langle v,\mathbf{1}_T\rangle$ is constant on the bases of every active table, v is constant on every molecule of the active family (7.8), and the active family of a connected family is one molecule (Lemma S3); so $v\in\mathbb{R}\mathbf{1}$. Conversely $\nabla^2\Phi\,\mathbf{1}=0$, $\Phi(y+c\mathbf{1})-\Phi(y)$ being linear in c. So the restriction of $\nabla^2\Phi(y^\star)$ to the chart $\{v_g=0\}$, the matrix $\big(\nabla^2\Phi(y^\star)\big)_{(g)}$, is positive definite; it is the Hessian at $y^\star$ of G on the chart.

The amplitude. For every basis T of table j, $|\langle\mathbf{1}_T,y\rangle|\le r_j|y|$, so $\log\min_T\theta_{j,T}-r_j|y|\le\log K_j(e^y)\le\log K_j(\mathbf{1})+r_j|y|$, and likewise for Ψ_j with $n-r_j$. Hence $|b(y)|=e^{\langle\operatorname{Re}\mathbf{m}_0,y\rangle}\prod_j K_j(e^y)^{-\operatorname{Re}s_{0,j}}\Psi_j(e^y)^{-\operatorname{Re}t_{0,j}}\le e^{c_0(1+|y|)}$ for a constant c_0, and b is continuous and nowhere 0.

Laplace's method. Lemma S7 on the chart, with $d=n-1$, the function $G(y^\star+x)-G(y^\star)$ and the amplitude $b(y^\star+x)$, bounded by $e^{c_0(1+|y^\star|+|x|)}$, gives

$$P_F(\mathbf{d}_\lambda)=e^{-\lambda G(y^\star)}\Big(\frac{2\pi}{\lambda}\Big)^{\frac{n-1}{2}}\det\big(\nabla^2\Phi(y^\star)\big)_{(g)}^{-1/2}\big(b(y^\star)+o(1)\big),$$

with $b(y^\star)=(\alpha^\star)^{\mathbf{m}_0}W_0(\alpha^\star)\ne0$ and $G(y^\star)=\Phi(\log\alpha^\star)-\langle\boldsymbol{\tau},\log\alpha^\star\rangle$: the display. The function $\alpha\mapsto\alpha^{\mathbf{m}_0}W_0(\alpha)$ is homogeneous of degree $\kappa_{\mathcal{E}}(\mathbf{m}_0;\mathbf{s}_0,\mathbf{t}_0)=0$, so $b(y^\star)$ does not depend on the scale of $\alpha^\star$; likewise $G(y+c\mathbf{1})=G(y)$, the data $(\boldsymbol{\tau};\mathbf{s},\mathbf{t})$ being balanced, and $\nabla^2\Phi$ does not change along $\mathbf{1}$. By 9.4, rung two of the still of $((s_j,t_j)_j;\alpha^\star)$ is $4\nabla^2\Phi(\log\alpha^\star)$.

The normal limit. For real $(\mathbf{m}_0;\mathbf{s}_0,\mathbf{t}_0)$ and λ large, $\operatorname{Breta}^\circ(F;\mathbf{d}_\lambda)$ is defined (8.10). For a bounded continuous function H of y modulo $\mathbb{R}\mathbf{1}$, the function $u\mapsto H(\log u)u^{\mathbf{m}-\mathbf{1}}W(u)$ is homogeneous of degree $-n$, so its integral over $\Delta_{\mathcal{E}}$ is its integral over the chart, as in the proof of Lemma S4(ii). So the law of $Y=\log U$ modulo $\mathbb{R}\mathbf{1}$, read on the chart, has the density $b(y)e^{-\lambda G(y)}/P_F(\mathbf{d}_\lambda)$, with $b>0$ continuous. Applying Lemma S7 as above to $H(\sqrt{\lambda}(y-y^\star))$ and to 1, and dividing,

$$\mathbb{E}\big[H\big(\sqrt{\lambda}(Y-y^\star)\big)\big]\to\int H(x)e^{-\frac12\langle x,\nabla^2\Phi(y^\star)_{(g)}x\rangle}dx\Big/\int e^{-\frac12\langle x,\nabla^2\Phi(y^\star)_{(g)}x\rangle}dx,$$

the expectation of H under the centred normal law on the chart with covariance $\big(\nabla^2\Phi(y^\star)_{(g)}\big)^{-1}$: the centred normal law on $\mathbb{R}^{\mathcal{E}}/\mathbb{R}\mathbf{1}$ with covariance $(\nabla^2\Phi)^{-1}$, the quadratic form of $\nabla^2\Phi(y^\star)$ on $\mathbb{R}^{\mathcal{E}}/\mathbb{R}\mathbf{1}$ being read on the chart. At $(\mathbf{m}_0;\mathbf{s}_0,\mathbf{t}_0)=0$, $b=1$ and this is the reference, proof of 18.9. □

Remark. At $(\mathbf{m}_0;\mathbf{s}_0,\mathbf{t}_0)=0$ let q be the question of the data $(\boldsymbol{\tau};\mathbf{s},\mathbf{t})$ (17.1), with the exponent $X(z)=2\langle\boldsymbol{\mu}_\perp,z\rangle-\sum_j\big(\sigma_jE_j(z)+\delta_jO_j(z)\big)$, read at the representative of z in $\mathbf{1}^\perp$. By 8.19, $\Phi(y)=\sigma\langle\mathbf{1},y\rangle+\sum_j\big(\sigma_jE_j(z)+\delta_jO_j(z)\big)$ in $y=2z$, and $\langle\boldsymbol{\tau},y\rangle=2\langle\boldsymbol{\mu},z\rangle+\sigma\langle\mathbf{1},y\rangle$, $\boldsymbol{\tau}$ being the masses of the question; so $\langle\boldsymbol{\tau},y\rangle-\Phi(y)=X(z)$ for $z\in\mathbf{1}^\perp$, and both sides are unchanged along $\mathbf{1}$. Hence $e^{-\lambda(\Phi(y^\star)-\langle\boldsymbol{\tau},y^\star\rangle)}=e^{\lambda X(z^\star)}$, $z^\star$ the tilt of $\frac12y^\star$. The Hessian in z is four times the Hessian in y, so on a chart $\det\big(-\nabla^2X(z^\star)\big)=4^{n-1}\det\big(\nabla^2\Phi(y^\star)\big)_{(g)}$, and

$$2^{n-1}e^{\lambda X(z^\star)}\Big(\frac{2\pi}{\lambda}\Big)^{\frac{n-1}{2}}\det\big(-\nabla^2X(z^\star)\big)^{-\frac12}=e^{-\lambda(\Phi(y^\star)-\langle\boldsymbol{\tau},y^\star\rangle)}\Big(\frac{2\pi}{\lambda}\Big)^{\frac{n-1}{2}}\det\big(\nabla^2\Phi(y^\star)\big)_{(g)}^{-1/2}:$$

the leading term of 17.5(ii) at real λ is the display of 18.9.

Definition 18.10 (Skeleton law). As stated, at real nonzero letter exponents.

Proof of the last clause. For a real coefficient $\xi_\ell>0$ and $y>0$, $(y+\xi_\ell)^{-w_\ell}>0$. A coefficient that is not real comes with its conjugate and the same real letter exponent w_ℓ; $y+\xi_\ell$ and $y+\bar\xi_\ell$ are conjugate and off $(-\infty,0]$, so their principal powers are conjugate and $(y+\xi_\ell)^{-w_\ell}(y+\bar\xi_\ell)^{-w_\ell}=|y+\xi_\ell|^{-2w_\ell}>0$. So $y^{\kappa-1}\prod_\ell(y+\xi_\ell)^{-w_\ell}$ is positive and continuous on $(0,\infty)$. As $y\to0$ it is asymptotic to $y^{\kappa-1}\prod_\ell\xi_\ell^{-w_\ell}$, the product being positive by the same pairing, and as $y\to\infty$ to $y^{\kappa-1-|\mathbf{w}|}$; so it is integrable on $(0,\infty)$ exactly when $0<\kappa<|\mathbf{w}|$. Its integral is the value of 15.1, which asks no sign of the letter exponents; so the normalizer is that value, positive, and the density is that of a law. □

Theorem 18.11 (The Skeleton law). *As stated: (i) off the balance wall and at exponents of any sign; (ii) at real nonzero letter exponents; (iii) about every point $r\ge\max_\ell\xi_\ell$ of the axis.*

Proof. (i) By 18.3, given the internal shapes (V_B,V_R) the scale ρ of B has a density proportional to $\rho^{m_B-1}(1+\rho)^{-\kappa_\mathcal{E}}\prod_jK_j(\rho V_B,V_R)^{-s_j}\Psi_j(\rho V_B,V_R)^{-t_j}$. At the gauge $\alpha=(V_B,V_R)$, 12.10 gives

$$K_j(\rho\alpha_B,\alpha_R)=\rho^{d_j(B)}K_j(\alpha)\prod_i\frac{\rho+\xi_{j,i}}{1+\xi_{j,i}},\qquad\Psi_j(\rho\alpha_B,\alpha_R)=\rho^{d_j^*(B)}\Psi_j(\alpha)\prod_i\frac{\rho+\xi^*_{j,i}}{1+\xi^*_{j,i}},$$

over the Skeleton values $\xi_{j,i}$ and $\xi^*_{j,i}$ of the two letters. The Skeleton polynomials are real, so their values not real come in conjugate pairs of equal multiplicity; the exponents are real, so the principal powers of conjugate factors are conjugate, and $K_j(\rho\alpha_B,\alpha_R)^{-s_j}=\rho^{-s_jd_j(B)}K_j(\alpha)^{-s_j}\prod_i(\rho+\xi_{j,i})^{-s_j}(1+\xi_{j,i})^{s_j}$, likewise for Ψ_j. The power of ρ collects to $\rho^{m_B-1-\sum_j(s_jd_j(B)+t_jd_j^*(B))}=\rho^{\kappa_B-1}$ (8.1), and the linear factors collect to $\prod_\ell(\rho+\xi_\ell)^{-w_\ell}$ over the distinct points of the joint spectrum of the letters with nonzero exponent, with the letter exponents w_ℓ of 15.3. The factor $(1+\rho)^{-\kappa_\mathcal{E}}$ is the coefficient 1 with the letter exponent $\kappa_\mathcal{E}$, added to the letter exponent of 1 when 1 is a point of the joint spectrum; discarding the coefficients of letter exponent 0 changes nothing. So the conditional density is proportional to $\rho^{\kappa_B-1}\prod_\ell(\rho+\xi'_\ell)^{-w'_\ell}$, with coefficients in $\mathbb{C}\setminus(-\infty,0]$ closed under conjugation and real nonzero letter exponents, equal on conjugate coefficients. Their total is $|\mathbf{w}|+\kappa_\mathcal{E}=\kappa_B+\kappa_B^{\text{top}}+\kappa_\mathcal{E}$ (15.3), which is $\kappa_B+\kappa_{\mathcal{E}\setminus B}$ (8.13); B and $\mathcal{E}\setminus B$ are nonempty proper sets and every proper wall is positive, so $0<\kappa_B<|\mathbf{w}'|$, and the conditional law is $\mathrm{Skel}_{\mathbf{w}',\kappa_B}(\boldsymbol{\xi}')$ (18.10). On the balance wall this is the reference, proof of 18.11(i).

(ii) For $-\kappa<\operatorname{Re}k<|\mathbf{w}|-\kappa$, $\mathbb{E}[Y^k]$ is $\int_0^\infty y^{\kappa+k-1}\prod_\ell(y+\xi_\ell)^{-w_\ell}dy$ over $\int_0^\infty y^{\kappa-1}\prod_\ell(y+\xi_\ell)^{-w_\ell}dy$, both convergent, the values of 15.1 at the indices $\kappa+k$ and κ; for positive letter exponents the factors $\Gamma(w_\ell)$ of the two stacked Gammas cancel, which is the display. For the inversion put $y=1/z$: $dy=z^{-2}dz$, and $y+\xi=\xi z^{-1}(z+\xi^{-1})$ with $\operatorname{Log}(y+\xi)=\operatorname{Log}\xi-\log z+\operatorname{Log}(z+\xi^{-1})$, the

principal arguments of ξ and of $z+\xi^{-1}$ having opposite signs and sum in $(-\pi,\pi)$. So the density of $1/Y$ is proportional to $z^{1-\kappa}z^{-2}z^{|\mathbf{w}|}\prod_\ell(z+\xi_\ell^{-1})^{-w_\ell} = z^{|\mathbf{w}|-\kappa-1}\prod_\ell(z+\xi_\ell^{-1})^{-w_\ell}$, the constant $\prod_\ell \xi_\ell^{-w_\ell}$ being positive; with $0<|\mathbf{w}|-\kappa<|\mathbf{w}|$ this is $\mathrm{Skel}_{\mathbf{w},|\mathbf{w}|-\kappa}(\boldsymbol{\xi}^{-1})$. This is the reference, proof of 18.11(ii), with 15.7, which uses no sign of the letter exponents.

(iii) The coefficients are real, hence positive, and $r\ge\max_\ell\xi_\ell$, so $|\xi_\ell-r|<r$ and $0\le g_\ell<1$. By the expansion in the proof of 15.6,

$$y^{\kappa-1}\prod_\ell(y+\xi_\ell)^{-w_\ell} = \sum_{\mathbf{n}\in\mathbb{N}^J}\prod_\ell \frac{(w_\ell)_{n_\ell}}{n_\ell!}(r-\xi_\ell)^{n_\ell}\,y^{\kappa-1}(y+r)^{-|\mathbf{w}|-|\mathbf{n}|},$$

with nonnegative terms, the letter exponents being positive. For $a>\kappa>0$, the law $\mathrm{Skel}_{a,\kappa}(1)$ has the density $y^{\kappa-1}(1+y)^{-a}/\Gamma_1^2\left[\begin{matrix}\kappa,\ a-\kappa\\ a\end{matrix}\right]$, the Breta of one coefficient 1 being 1 (the paragraph after 15.1); so rY_a, $Y_a\sim\mathrm{Skel}_{a,\kappa}(1)$, has the density $r^{a-\kappa}y^{\kappa-1}(y+r)^{-a}/\Gamma_1^2\left[\begin{matrix}\kappa,\ a-\kappa\\ a\end{matrix}\right]$. With $a=|\mathbf{w}|+|\mathbf{n}|$ and $(r-\xi_\ell)^{n_\ell}=r^{n_\ell}g_\ell^{n_\ell}$, the density of Y is the sum over $\mathbf{n}$ of $r^{\kappa-|\mathbf{w}|}\prod_\ell\frac{(w_\ell)_{n_\ell}}{n_\ell!}g_\ell^{n_\ell}\Gamma_1^2\left[\begin{matrix}\kappa,\ |\mathbf{w}|+|\mathbf{n}|-\kappa\\ |\mathbf{w}|+|\mathbf{n}|\end{matrix}\right]$ times the density of $rY_{\mathbf{n}}$, divided by the normalizer; the coefficients are nonnegative and, by Tonelli, sum to 1. So Y is the stated mixture. At $r=\max_\ell\xi_\ell$ the largest coefficient has $g_\ell=0$, and only $n_\ell=0$ contributes.

(iv) On the balance wall with $s_j,t_j\ge0$, given the shapes the density of the scale ρ is proportional to the integrand of the scale integral at $\alpha=(V_B,V_R)$, by (i). By the proof of 15.9(i) it is, on $(0,1)$, proportional to $\rho^{\kappa_B-1}\prod_i\mathsf{Q}_{B,i}(\rho;\alpha)^{-w_i}$, and the density of $1/\rho$ on $(0,1)$ is proportional to $y^{\kappa_B^{\mathrm{top}}-1}\prod_i\mathsf{Q}_{R,i}(y;\alpha)^{-w_i}$. The expansions of 15.9(ii) have nonnegative terms, each the term of $\mathbf{n}$ and k times $y^{\kappa+k-1}(1-y)^{|\mathbf{n}|}/\Gamma_1^2\left[\begin{matrix}\kappa+k,\ |\mathbf{n}|+1\\ \kappa+k+|\mathbf{n}|+1\end{matrix}\right]$, the density of the first coordinate of $\mathrm{Dir}_{(\kappa+k,|\mathbf{n}|+1)}$ (3.9); by Tonelli the conditional laws are the stated mixtures, and the two sectors carry probabilities proportional to their Trailmoments. This is the reference, proof of 18.11(v). □

Definition 18.12 (Wall contour; joint period). As stated, at complex data on the balance wall with $\mathrm{Re}\,s_j>0$ or $s_j=0$, and $\mathrm{Re}\,t_j>0$ or $t_j=0$.

Remark. A wall contour is fixed by real parts alone, and the fibre integral at B has complex pins, whose admissible real points (4.1) are the wall contours. The two descriptions agree: $\mathrm{load}_e=\sigma+\langle\boldsymbol{\delta}\rangle_e$ on the share sums and $m_e=\sigma+\mu_e$, so $\mathrm{Re}\,\mathrm{load}_e=\mathrm{Re}\,m_e$ exactly when $\mathrm{Re}\langle\boldsymbol{\delta}\rangle_e=\mathrm{Re}\,\mu_e$. For real data with $s_j,t_j\ge0$ these are the conditions of the reference.

Theorem 18.13 (The port on the balance wall). *As stated, at complex data on the balance wall with* $\mathrm{Re}\,s_j>0$ *or* $s_j=0$, *and* $\mathrm{Re}\,t_j>0$ *or* $t_j=0$.

Proof. A letter with exponent 0 is 1 and is not opened; the shares, the stacked Gammas and the products below run over the letters with nonzero exponent, whose exponents have positive real part.

The real parts. The walls and the imbalance are affine in the data with real coefficients. So the data $(\mathrm{Re}\,\mathbf{m};\mathrm{Re}\,\mathbf{s},\mathrm{Re}\,\mathbf{t})$ lie on the balance wall, and their proper walls are the real parts of those of $(\mathbf{m};\mathbf{s},\mathbf{t})$, positive since $P_F(\mathbf{m};\mathbf{s},\mathbf{t})$ converges (8.7). Their exponents are nonnegative and not all zero: otherwise $\kappa_S=\mathrm{Re}\,m_S$ for every S, and $0=\kappa_{\mathcal{E}}=\kappa_B+\kappa_R>0$. Their masses are positive: $\mathrm{Re}\,m_e=\kappa_{\{e\}}+\sum_j\big(\mathrm{Re}\,s_j\,d_j(\{e\})+\mathrm{Re}\,t_j\,d_j^*(\{e\})\big)>0$, $\{e\}$ being a nonempty proper set ($n\ge2$, as B is proper). A nonempty proper S with $c_j(S)=0$ in every active table would have

$\kappa_S+\kappa_{\mathcal{E}\setminus S}=\kappa_{\mathcal{E}}=0$ at the real parts (8.16), against the positivity of both walls; so F is connected, and its active family, whose tables are those of the real parts, is one molecule (Lemma S3). By 8.19(iii) the real parts have a native gauge.

(i), convergence and the room integral. By 7.15(i), $K_j=e^{\langle\mathbf{1},z\rangle}\Lambda_j(z)$ and $\Psi_j=e^{\langle\mathbf{1},z\rangle}\Lambda_j(-z)$ at $\alpha=e^{2z}$, so with $\sigma=\sum_j\sigma_j$ the integrand of P_F is $f(\alpha)=\alpha^{\boldsymbol{\mu}-\mathbf{1}}\prod_j\Lambda_j(z)^{-s_j}\Lambda_j(-z)^{-t_j}$, homogeneous of degree $\kappa_{\mathcal{E}}-n=-n$ (7.15(iii), 8.2(iii)), and $|f|$ is the same function at the real parts of the data. At the real parts, 8.7 on the section $|\alpha_R|=1$, whose measure is $d\alpha_B\,d\omega_R$ (proof of 16.6 above), gives $\int_{\Delta_R}\int_{\mathbb{R}^B_{>0}}|f(\alpha_B,v)|\,d\alpha_B\,d\omega_R(v)<\infty$; and $f(\alpha_B,v)$ is $v^{\boldsymbol{\mu}|_R-\mathbf{1}}$ times the integrand of $\Xi_B(v;\boldsymbol{\mu}|_B;\mathbf{s},\mathbf{t})$. By Tonelli that integral converges absolutely at almost every $v\in\Delta_R$. For two room points α_R,α'_R there is $C\geq1$ with $\Lambda_{j,(p)}(\pm z_R)\leq C\Lambda_{j,(p)}(\pm z'_R)$ for all j,p, these being finite sums of positive terms; by 12.7, $\Lambda_j(z)=\sum_p e^{\langle z_B,\chi_p\rangle}\Lambda_{j,(p)}(z_R)$, so $\Lambda_j(z_B,z_R)\geq C^{-1}\Lambda_j(z_B,z'_R)$, likewise at $-z$, and the modulus of the integrand of Ξ_B at α_R is at most $C^{\sum_j(\operatorname{Re}s_j+\operatorname{Re}t_j)}$ times that at α'_R. So Ξ_B converges at every α_R, and Fubini gives $P_F=\int_{\Delta_R}v^{\boldsymbol{\mu}|_R-\mathbf{1}}\Xi_B(v)\,d\omega_R(v)$.

Independence of the pins. Let $R_1,\dots,R_q$ be the molecules of the children (for $q=1$ there are no pins κ_{R_i} below), and write $\kappa_{R_i}=m_{R_i}-\ell_i$ with $\ell_i(\mathbf{a},\mathbf{b})=\sum_{j,p}\big(a_{j,p}r_{j,(p)}(R_i)+b_{j,p}(|R_i|-r_{j,(p)}(R_i))\big)$. The linear forms $|\mathbf{a}_j|$ and $|\mathbf{b}_j|$ of the letters, $\langle\boldsymbol{\delta}\rangle_e$ for $e\in B$, and ℓ_i for $i<q$, are linearly independent. Indeed, let $\sum_{e\in B}\gamma_e\langle\boldsymbol{\delta}\rangle_e+\sum_{i<q}w_i\ell_i=\sum_j(u_j|\mathbf{a}_j|+u'_j|\mathbf{b}_j|)$, and put $V\in\mathbb{R}^{\mathcal{E}}$ equal to γ on B, to w_i on R_i for $i<q$ and to 0 on R_q. For a basis T of table j with $T\cap B=p$, $T\setminus B$ is a basis of the child (j,p), which meets each R_i in $r_{j,(p)}(R_i)$ marks, R_i being a union of molecules of that child (7.9); and $\frac12\langle\gamma,\chi_p\rangle=\langle\gamma,\mathbf{1}_p\rangle-\frac12\langle\gamma,\mathbf{1}_B\rangle$. Comparing the coefficients of $a_{j,p}$ gives $\langle V,\mathbf{1}_T\rangle=u_j+\frac12\langle\gamma,\mathbf{1}_B\rangle$, and comparing those of $b_{j,p}$ gives $\langle V,\mathbf{1}_T\rangle=\langle V,\mathbf{1}_R\rangle+\frac12\langle\gamma,\mathbf{1}_B\rangle-u'_j$, for every basis T of table j whenever that letter is opened. So $\langle V,\mathbf{1}_T\rangle$ is constant on the bases of every active table; by 7.8 V is constant on the one molecule $\mathcal{E}$ of the active family, and as it vanishes on $R_q\neq\varnothing$, $V=0$: $\gamma=0$ and every $w_i=0$.

(i), the fibre formula. Fix α_R and a wall contour. Put $X_{j,p}=e^{\langle z_B,\chi_p\rangle}\Lambda_{j,(p)}(z_R)$ and $Y_{j,p}=e^{-\langle z_B,\chi_p\rangle}\Lambda_{j,(p)}(-z_R)$, positive, so that $\Lambda_j(z)=\sum_p X_{j,p}$ and $\Lambda_j(-z)=\sum_p Y_{j,p}$. For a letter with more than one pattern, 4.4 on the contour $\operatorname{Re}a_{j,p}=c_{j,p}$, admissible since every $c_{j,p}>0$ and $\sum_p c_{j,p}=\operatorname{Re}s_j$, gives $\Lambda_j(z)^{-s_j}=\int_{|\mathbf{a}_j|=s_j}\Gamma_{|\operatorname{pat}_j(B)|}\begin{bmatrix}\mathbf{a}_j\\ s_j\end{bmatrix}\prod_p X_{j,p}^{-a_{j,p}}$; for one pattern this is the evaluation $a_{j,p}=s_j$. Likewise for $\Lambda_j(-z)^{-t_j}$ with the shares $\mathbf{b}_j$. Since $\prod_{j,p}e^{-\langle z_B,\chi_p\rangle(a_{j,p}-b_{j,p})}=e^{-2\langle z_B,\langle\boldsymbol{\delta}\rangle\rangle}=\alpha_B^{-\langle\boldsymbol{\delta}\rangle}$ (12.24), in $y=\log\alpha_B$, where $\alpha_B^{\boldsymbol{\mu}|_B-\mathbf{1}}d\alpha_B=e^{\langle\boldsymbol{\mu}|_B,y\rangle}dy$,

$$\Xi_B(\alpha_R)=\int_{\mathbb{R}^B}\Big(\int_{\mathcal{X}_0}\mathcal{G}(\mathbf{a},\mathbf{b})\,e^{\langle\boldsymbol{\mu}|_B-\langle\boldsymbol{\delta}\rangle,y\rangle}\Big)dy,$$

$$\mathcal{G}=\prod_j\Gamma_{|\operatorname{pat}_j(B)|}\begin{bmatrix}\mathbf{a}_j\\ s_j\end{bmatrix}\Gamma_{|\operatorname{pat}_j(B)|}\begin{bmatrix}\mathbf{b}_j\\ t_j\end{bmatrix}\prod_{j,p}\Lambda_{j,(p)}(z_R)^{-a_{j,p}}\Lambda_{j,(p)}(-z_R)^{-b_{j,p}},$$

the inner integral the product of the share integrals, over the set $\mathcal{X}_0$ of shares on the contour with the share sums pinned. On a wall contour $\operatorname{Re}\langle\boldsymbol{\delta}\rangle_e=\operatorname{Re}\mu_e$ for $e\in B$, so $e^{\langle\boldsymbol{\mu}|_B-\langle\boldsymbol{\delta}\rangle,y\rangle}=e^{i\langle\operatorname{Im}\boldsymbol{\mu}|_B-\operatorname{Im}\langle\boldsymbol{\delta}\rangle,y\rangle}$. By Stirling's formula $|\Gamma(c+i\eta)|\leq C_c(1+|\eta|)^{c-1/2}e^{-\pi|\eta|/2}$, so $|\mathcal{G}|$, whose factors $\Lambda_{j,(p)}^{-a_{j,p}}$ have moduli constant on the contour, decays exponentially along every imaginary direction of $\mathcal{X}_0$, uniformly on parallel affine subspaces through a compact set. The map $(\mathbf{a},\mathbf{b})\mapsto\operatorname{Im}\langle\boldsymbol{\delta}\rangle\in\mathbb{R}^B$ is affine on $\mathcal{X}_0$, with linear part onto $\mathbb{R}^B$ by the independence of the pins; so the image of $\mathcal{G}$ times the measure of the share integrals has a density g on $\mathbb{R}^B$, continuous and integrable, and the inner integral is $e^{i\langle\operatorname{Im}\boldsymbol{\mu}|_B,y\rangle}\hat g(y)$, $\hat g(y)=\int g(\nu)e^{-i\langle\nu,y\rangle}d\nu$. The modulus $|\hat g(y)|$ is the modulus of the integrand of Ξ_B in y, integrable by the first step. By Fourier inversion, $\Xi_B(\alpha_R)=\int\hat g(y)e^{i\langle\operatorname{Im}\boldsymbol{\mu}|_B,y\rangle}dy=$

$(2\pi)^{|B|}g(\operatorname{Im}\boldsymbol{\mu}|_B)$, which is the fibre integral of $\mathcal{G}$ over the fibre $\mathcal{X}_1$ cut by the pins $|\mathbf{a}_j| = s_j$, $|\mathbf{b}_j| = t_j$ and $\langle\boldsymbol{\delta}\rangle = \boldsymbol{\mu}|_B$ (4.1: the $|B|$ further pins raise $(2\pi)^{q-N}$ by $(2\pi)^{|B|}$ and add the factor $\delta^{|B|}(\operatorname{Im}\langle\boldsymbol{\delta}\rangle - \operatorname{Im}\boldsymbol{\mu}|_B)$), with the wall contour as its admissible real point. This is the display of (i). For real data this is the reference, proof of 18.13(i), where $\operatorname{Im}\boldsymbol{\mu}|_B = 0$.

(ii). On the pins of (i), $\operatorname{load}_e = m_e$ for $e \in B$, and by 12.2 the child (j,p) has rank $r_j - |p|$; so

$$\sum_{i=1}^{q}\kappa_{R_i} = m_R - \sum_{j,p}\big(a_{j,p}(r_j-|p|)+b_{j,p}(|R|-r_j+|p|)\big) = m_R - \sum_j\big(s_jr_j+t_jr_j^*\big)+\sum_{e\in B}\operatorname{load}_e = \kappa_{\mathcal{E}} = 0,$$

using $\sum_{e\in B}\operatorname{load}_e = \sum_{j,p}\big(a_{j,p}|p|+b_{j,p}(|B|-|p|)\big)$; so $\kappa_{R_q} = 0$ holds on $\mathcal{X}$. Take the section $\{|\alpha_{R_q}| = 1\}$, with the measure $d\alpha_B\prod_{i<q}d\alpha_{R_i}\,d\omega_{R_q}$, and as in (i) $P_F = \int \alpha_R^{\boldsymbol{\mu}|_R-\mathbf{1}}\,\Xi_B(\alpha_R)\prod_{i<q}d\alpha_{R_i}\,d\omega_{R_q}$, absolutely convergent. Write $\alpha_{R_i} = e^{y_i}u_i$, $u_i \in \Delta_{R_i}$, for $i<q$, and $u_q = \alpha_{R_q}$; then $\alpha_{R_i}^{\boldsymbol{\mu}|_{R_i}-\mathbf{1}}d\alpha_{R_i} = e^{y_i\mu_{R_i}}u_i^{\boldsymbol{\mu}|_{R_i}-\mathbf{1}}dy_i\,d\omega_{R_i}$. Each R_i is a union of molecules of every child, so every basis X of the child (j,p) has $\langle\chi_X,\mathbf{1}_{R_i}\rangle = 2r_{j,(p)}(R_i) - |R_i|$, and $\Lambda_{j,(p)}(z_R + \frac12 y_i\mathbf{1}_{R_i}) = e^{\frac12 y_i(2r_{j,(p)}(R_i)-|R_i|)}\Lambda_{j,(p)}(z_R)$. Inserting the fibre formula of (i) and using $\sum_{j,p}\sigma_{j,p} = \sigma$, the exponent of e^{y_i} collects to $\mu_{R_i} - \sum_{j,p}\delta_{j,p}\big(2r_{j,(p)}(R_i) - |R_i|\big) = \kappa_{R_i}(\mathbf{a},\mathbf{b})$, and the rest is $\mathcal{G}$ at u times $u^{\boldsymbol{\mu}|_R-\mathbf{1}}$, that is, by 7.15 and $\sum_{j,p}\sigma_{j,p} = \sigma$, the stacked Gammas times the integrand of the joint period of the children at the masses $\mathbf{m}|_R$. For fixed $\mathbf{y} = (y_i)_{i<q}$, on a wall contour with $\operatorname{Re}\kappa_{R_i} = 0$ for $i<q$, the modulus of this integrand over $u \in \prod_i\Delta_{R_i}$ and the shares is the modulus of the stacked Gammas times the joint integrand at the real parts $(\operatorname{Re}\mathbf{m}|_R;\mathbf{c},\mathbf{c}')$, integrable by the hypothesis on $P^{\otimes}$ and by Stirling; so by Fubini the integral over u and the shares is

$$\hat g_1(\mathbf{y}) = \int_{\mathcal{X}_1}\prod_j \Gamma_{|\operatorname{pat}_1^j(B)|}\begin{bmatrix}\mathbf{a}_j\\ s_j\end{bmatrix}\Gamma_{|\operatorname{pat}_1^j(B)|}\begin{bmatrix}\mathbf{b}_j\\ t_j\end{bmatrix}\;P^{\otimes}_{F_B(\mathbf{a},\mathbf{b})}(\mathbf{m}|_R;\mathbf{a},\mathbf{b})\,e^{i\sum_{i<q}y_i\operatorname{Im}\kappa_{R_i}(\mathbf{a},\mathbf{b})},$$

$\mathcal{X}_1$ the fibre of (i), and $\int|\hat g_1(\mathbf{y})|\,d\mathbf{y}$ is at most P_F at the real parts, finite. The joint period is continuous in the shares and bounded by its value at the real parts, by dominated convergence. The map $(\mathbf{a},\mathbf{b}) \mapsto (\operatorname{Im}\kappa_{R_i})_{i<q}$ is affine on $\mathcal{X}_1$ with linear part onto $\mathbb{R}^{q-1}$, by the independence of the pins. So, as in (i), Fourier inversion in $\mathbf{y}$ gives $P_F = \int\hat g_1(\mathbf{y})\,d\mathbf{y}$ as the fibre integral over $\mathcal{X}$, the pins $\kappa_{R_i} = 0$, $i<q$, holding in real part on the contour and in imaginary part by inversion. For $q=1$ there is no $\mathbf{y}$, and $P_F = \hat g_1$ by Fubini.

(iii). The real parts have a native gauge (first step). For real data the statement is the reference, proof of 18.13(iii): the native split is a wall contour, lies on the real fibre, and $P^{\otimes}$ converges there. A wall contour, and the real parts of the pins of $\mathcal{X}$, $\operatorname{Re}|\mathbf{a}_j| = \operatorname{Re}s_j$, $\operatorname{Re}|\mathbf{b}_j| = \operatorname{Re}t_j$, $\operatorname{Re}\langle\boldsymbol{\delta}\rangle = \operatorname{Re}\boldsymbol{\mu}|_B$ and $\operatorname{Re}\kappa_{R_i} = \kappa_{R_i}(\operatorname{Re}\mathbf{m}|_R;\mathbf{c},\mathbf{c}')$, involve the data only through their real parts. So the native split of the real parts is a wall contour for the data, an admissible real point of $\mathcal{X}$, and $P^{\otimes}_{F_B(\mathbf{c},\mathbf{c}')}(\operatorname{Re}\mathbf{m}|_R;\mathbf{c},\mathbf{c}')$ converges there, as (ii) asks. □

Proposition 18.17 (The pins reach every integer point). *As stated.*

Proof. The pins are a linear map $\mathbb{Z}^{\text{shares}} \to \mathbb{Z}^{\text{rows}}$, the rows being the share sums of the active letters and the loads at the marks $e \neq g$; a share $a_{j,T}$ has 1 in the row of its sum and in the loads of the marks of $T-g$, and a share $b_{j,T}$ has 1 in the row of its sum and in the loads of the marks of $\mathcal{E}\setminus T$ other than g. Write $\mathbf{e}_x$ for the unit vector of the load of $x \neq g$ and $\mathbf{e}_g = 0$. If $x \neq y$ lie in a common circuit of table j, 7.7 gives a basis $T \ni x$, $T \not\ni y$ with $T' = (T\setminus\{x\})\cup\{y\}$ a basis; if K_j is active the difference of the columns of $a_{j,T}$ and $a_{j,T'}$ is $\mathbf{e}_x - \mathbf{e}_y$, and if Ψ_j is active that of $b_{j,T}$ and $b_{j,T'}$ is $\mathbf{e}_y - \mathbf{e}_x$. Along the sequences of the hypothesis every $\mathbf{e}_x - \mathbf{e}_y$ lies in the image,

and with $y = g$ every $\mathbf{e}_x$, $x \neq g$. Subtracting from the column of a share the loads it carries leaves the unit vector of its share sum. So the image is all of $\mathbb{Z}^{\mathrm{rows}}$.

At integer data the target point is an integer point, so it has an integer preimage x_0, and the integer points of the fibre are $x_0 + \Lambda$ with Λ the kernel of the map on $\mathbb{Z}^{\mathrm{shares}}$. The map is onto a free module of the rank of the number of rows, so the rows are independent and Λ, a subgroup of $\mathbb{Z}^{\mathrm{shares}}$, is free of rank the number of shares less the number of rows, the dimension of the fibre. With a basis $v_1, \dots, v_D$ of Λ the point $x_0 + \sum_i z_i v_i$ is an integer point exactly when $z \in \mathbb{Z}^D$. □

Proposition 18.20 (The serif word is the closed form of the periods). *As stated.*

Proof. (i) The Gramma of one scale with the configuration (1) and the coefficient 1 is $\int_0^\infty x^{\nu-1} e^{-x}\, dx = \Gamma(\nu)$ (Definition 2.1), and the stacked Gamma is a quotient of such values (Definition 1.2), meromorphic in its entries. The domain of the Gramma is Theorem 2.2, and the fibre integral is fixed by its pins and independent of its admissible real point within one connected set of them (Definition 4.1). (ii) is Corollaries 18.16 and 18.18, and (iii) is the cited statements.

(iv) F_{m} has the masses $2k = k \cdot 1 + k \cdot 1$, its active letters, K of the first copy and Ψ of the second, being of degree one, so it is on the balance wall; on a singleton both floors of $\binom{[2]}{1}$ vanish, so its walls are $\kappa_{\{1\}} = \kappa_{\{2\}} = k > 0$, and it converges (Theorem 8.7). Apply Corollary 18.16 with $g = 2$ and one share per basis for each active letter, (a_1, a_2) for $K = \alpha_1 + \alpha_2$ and (b_1, b_2) for $\Psi = \alpha_2 + \mathsf{m}\alpha_1$, indexed by the bases $\{1\}$ and $\{2\}$. The pins $|\mathbf{a}| = |\mathbf{b}| = k$ and $\mathrm{load}_1 = a_1 + b_2 = k$ leave the free coordinate $x = a_1$, with $a_2 = b_2 = k - x$ and $b_1 = x$; the weights give $\mathsf{m}^{-b_2} = \mathsf{m}^{x-k}$, the stacked Gammas give $\Gamma_{\binom{2}{1}}\left[\begin{smallmatrix} x,\ k-x \\ k \end{smallmatrix}\right]^2$, and $\operatorname{Re} x = k/2$ is a wall contour. In the coordinates (a_1, a_2, b_1, b_2) the pins have the rows $(1,1,0,0)$, $(0,0,1,1)$, $(1,0,0,1)$, with $\det PP^{\mathsf{T}} = 4$, and the fibre has the direction $(1,-1,1,-1)$, of length 2, so the fibre integral is $\frac{1}{2\pi i}\int dx$ (Definition 4.1). On the section $\alpha_1 = 1$, with $u = \alpha_2$, the period is $\int_0^\infty u^{k-1}(1+u)^{-k}(u+\mathsf{m})^{-k}\, du$ (Theorem 8.7). For $0 < \mathsf{m} < 2$,

$$(u+\mathsf{m})^{-k} = (1+u)^{-k} \sum_{j \geq 0} \frac{(k)_j}{j!} \Big(\frac{1-\mathsf{m}}{1+u}\Big)^j,$$

and the series of the absolute values is at most $(1+u)^{-k}(1-|1-\mathsf{m}|)^{-k}$, so the sum and the integral exchange; $\int_0^\infty u^{k-1}(1+u)^{-2k-j}\, du = \Gamma(k)\Gamma(k+j)/\Gamma(2k+j)$, the Dirichlet integral on two marks after $u = v/(1-v)$ (Theorem 3.9), and $(k)_j\Gamma(k) = \Gamma(k+j)$.

In the second display the integrand is $\Gamma(-s)G(s)$ with $G(s) = \Gamma(1+s)(1+s)^{-n}(-z)^s$, and the line $\operatorname{Re} s = c$ separates the poles of $\Gamma(-s)$, at $s \in \mathbb{N}$, from those of G. Move it to the right. Only $\Gamma(-s)$ has poles crossed. For $0 < -z < 1$ the contribution of the line $\operatorname{Re} s = N + \frac{1}{2}$ tends to zero as $N \to \infty$: there $|\Gamma(-s)\Gamma(1+s)| = \pi/|\sin \pi s| \leq \pi/\cosh(\pi \operatorname{Im} s)$, $|1+s|^{-n} \leq 1$ and $|(-z)^s| = (-z)^{N+1/2}$; and on the strip between the two lines $\pi/|\sin \pi s| \leq \pi/\sinh(\pi|\operatorname{Im} s|)$, which decays exponentially in $|\operatorname{Im} s|$. So Theorem 4.5 gives $\sum_{j\geq 0} \frac{(-1)^j}{j!} G(j) = \sum_{j\geq 0} (-1)^j (1+j)^{-n}(-z)^j = \sum_{j\geq 0} z^j (1+j)^{-n}$, which is the display after the factor z. For every $z < 0$ the integrand is at most a constant times $e^{-\pi|\operatorname{Im} s|}$ on the line, $|(-z)^s|$ being $(-z)^c$ there, so the integral converges and is real analytic in z on $(-\infty, 0)$, and it agrees with the series on $(-1, 0)$. □

50.19 Chapter 19: bunches of width one: pooling and cleaning

Throughout this section, for a bunch B of width one of table j whose weights factor across B and R, $\theta_{j,T} = \theta'_{j,T\cap B}\, \theta''_{j,T\cap R}$, the minors $\mathcal{B}_j|B$ and $\mathcal{B}_j/R$ on B carry θ'_j and the minors $\mathcal{B}_j|R$ and $\mathcal{B}_j/B$ on R carry θ''_j (19.2), and every integral of a positive function is read in $[0, \infty]$ (Tonelli).

Proposition 19.3 (Hinge values of parallel and series bunches). *As stated, for classes of any table whose weights factor across them.*

Proof. That a parallel or series bunch has width at most one, and width zero exactly when it is a union of molecules, is the reference, proof of prop:classreadings. Let B be a parallel bunch of width one: $r(B) = 1$ and $c(B) = r(B) - d(B) = 1$, so $d(B) = 0$; $\mathcal{B}/R$ has rank 0, with the single basis $\varnothing$ and the weight $\theta'_{\varnothing}$, and $\mathcal{B}|B$ has rank one, with the singletons of B as bases, none of its marks being a loop, and the weights $\theta'_{\{e\}} = \theta'_{\varnothing} w_e$. Then $K_{\mathcal{B}/R} = \theta'_{\varnothing}$, $K_{\mathcal{B}|B} = \sum_e \theta'_{\{e\}} \alpha_e = \theta'_{\varnothing} \sum_e w_e \alpha_e$, $\Psi_{\mathcal{B}/R} = \theta'_{\varnothing} \alpha^B = \theta'_{\varnothing} e_{|B|}(\alpha_B)$ and $\Psi_{\mathcal{B}|B} = \sum_e \theta'_{\{e\}} \alpha^{B-e} = \theta'_{\varnothing} e_{|B|}(\alpha_B) \sum_e w_e \alpha_e^{-1}$, and the hinge values are the quotients of 19.2. Let B be a series bunch of width one: no mark of B is a coloop, so $d(B) \geq |B|-1$, and width one gives $r(B) = |B|$ and $d(B) = |B|-1$; $\mathcal{B}|B$ has the single basis B, with the weight θ'_B, and $\mathcal{B}/R$ the sets $B-e$, every one of them occurring since a basis avoids e, with the weights $\theta'_{B-e} = \theta'_B w_e$. Then $K_{\mathcal{B}|B} = \theta'_B e_{|B|}(\alpha_B)$, $K_{\mathcal{B}/R} = \theta'_B \sum_e w_e \alpha^{B-e} = \theta'_B e_{|B|}(\alpha_B) \sum_e w_e \alpha_e^{-1}$, $\Psi_{\mathcal{B}|B} = \theta'_B$ and $\Psi_{\mathcal{B}/R} = \theta'_B \sum_e w_e \alpha_e$, which give γ_B^{Ψ} and γ_B^K. In a list with $\theta' = \theta'' = 1$ every w_e is 1, and for a pair with the shape $(x, 1-x)$: parallel, $\gamma_B^K = 1$ and $\gamma_B^{\Psi} = (x^{-1} + (1-x)^{-1})^{-1} = x(1-x)$; series, $\gamma_B^{\Psi} = 1$ and $\gamma_B^K = x(1-x)$. □

Remark. A change of the factorization (19.2) multiplies the factors w_e of a parallel bunch by c, the weights of its level $r(B) = 1$ over those of its level $d(B) = 0$, and those of a series bunch by c^{-1}, its patterns $B - e$ lying on the level $d(B)$; either way γ_B^K is multiplied by c and γ_B^{Ψ} by c^{-1}. In exact arithmetic (receipt `check_classes_realization.py`): a parallel bunch of three marks whose cell of the bunch is $\binom{\{1,2,3,g\}}{1}$ with the weights $2, \frac{3}{7}, 5$ on the singletons of the bunch and $\frac{4}{3}$ on $\{g\}$, and a series bunch of three marks whose cell is $\binom{\{1,2,3,g\}}{3}$ with the weights $\frac{3}{2}$ on $\{1,2,3\}$ and $\frac{1}{5}, 7, \frac{2}{3}$ on the sets through g, each glued to a weighted room cell, have the hinge values of the statement as rational functions, and $\varrho_B = (\sum_e w_e)^{-2}$ at the centre of the shape simplex of the parallel bunch.

Theorem 19.4 (A bunch of width one is one mark to its room). *As stated; the converse holds with any number of products.*

Proof. All but the converse is the reference, proof of thm:widthone. On the open orthant let $K(\alpha) = \sum_{l=0}^{k} A_l(\alpha_B) C_l(\alpha_R)$, C_l homogeneous of degree D_l. Grouping the bases by their level $i = |T \cap B|$, which takes every value $d(B) \leq i \leq r(B)$ (7.13), $K = \sum_i K^{(i)}$ with $K^{(i)}(\alpha_B, \lambda\alpha_R) = \lambda^{r-i} K^{(i)}(\alpha)$ and $K^{(i)} > 0$ on the open orthant. At a fixed α, with $\lambda\alpha_R$ for α_R,

$$\sum_{i=d(B)}^{r(B)} \lambda^{r-i} K^{(i)}(\alpha) = \sum_D \lambda^D \sum_{l:\ D_l = D} A_l(\alpha_B)\, C_l(\alpha_R) \qquad (\lambda > 0),$$

the sum on the right over the distinct values D among the D_l. The functions $\lambda \mapsto \lambda^D$ with distinct real D are linearly independent on $(0, \infty)$, so each of the $c(B) + 1$ exponents $r - i$ on the left, whose coefficient is positive, is one of the D_l: $c(B) + 1 \leq k + 1$. With $k = 1$ this is the converse of the reference. □

Lemma 19.6 (One hinge value of any degree is width at most one). *As stated.*

Proof. Write $d = d(B)$, $c = c(B)$ and $K^{(k)} = \sum_{p \in \mathrm{pat}^{(k)}(B)} \alpha_B^p K_{(p)}(\alpha_R)$ for the level letters (12.16), nonzero exactly for $d \leq k \leq d + c$ (7.13); each child $K_{(p)}$ has positive coefficients, the weights. Let a be the degree of A and $P(\alpha_R, y) = \sum_{i=0}^{D} P_i(\alpha_R) y^i$. For $\tau > 0$,

$$\sum_k \tau^k K^{(k)}(\alpha) = K(\tau\alpha_B, \alpha_R) = \sum_{i=0}^{D} \tau^{a+i} A(\alpha_B) \gamma(\alpha_B)^i P_i(\alpha_R),$$

and at a fixed α the functions $\tau \mapsto \tau^x$ with distinct real x are linearly independent on $(0,\infty)$. So a is an integer, $K^{(d)}$ being nonzero, and $K^{(k)} = A\gamma^{k-a}P_{k-a}$ for every k, the right side read as 0 when $k-a \notin \{0,\dots,D\}$.

Let $d \le k \le d+c$. Then $P_{k-a} \not\equiv 0$; fixing α_R where $P_{k-a}(\alpha_R) \neq 0$ shows that $A\gamma^{k-a}$ is a polynomial $\widehat{f_k}$ in α_B, so $K^{(k)}(\alpha) = \widehat{f_k}(\alpha_B)P_{k-a}(\alpha_R)$ as polynomials. The coefficient of $\alpha_B^p\alpha_R^X$ in $K^{(k)}$ is the weight of $p \sqcup X$, distinct patterns giving distinct monomials α_B^p, so the matrix of these coefficients, rows indexed by the patterns of the level and columns by the monomials of the room, has rank one: the children at the patterns of the level are positive multiples of one polynomial C_k, $K_{(p)} = \lambda_p C_k$ with $\lambda_p > 0$, and $K^{(k)} = f_k(\alpha_B)C_k(\alpha_R)$ with $f_k = \sum_{p\in \mathrm{pat}^{(k)}(B)} \lambda_p \alpha_B^p$. Comparing with $A\gamma^{k-a}P_{k-a}$ at a fixed α_R where C_k and P_{k-a} do not vanish, $f_k = \mu_k A\gamma^{k-a}$ with a constant $\mu_k > 0$.

Suppose $c \ge 2$. Then $f_{d+1}^2 = \mu\, f_d f_{d+2}$ on the open orthant with $\mu = \mu_{d+1}^2/(\mu_d\mu_{d+2}) > 0$, an identity of polynomials. For a pattern p of $d+1$ marks the monomial $\alpha_B^{2\mathbf{1}_p}$ has the coefficient $\lambda_p^2 > 0$ in f_{d+1}^2, since a product $\alpha_B^{p'}\alpha_B^{p''}$ of two monomials of sets equals it only for $p' = p'' = p$; in $f_d f_{d+2}$ it would need two sets q, q' with $q = q' = p$, against $|q| = d \neq d+2 = |q'|$. So $c \le 1$.

Conversely, with the weights factoring across B and R: at $c = 0$ the one level consists of the unions of a pattern and a room side, all combinations occurring (12.19), so $K = K_{\mathcal{B}|B}(\alpha_B)K_{\mathcal{B}|R}(\alpha_R)$ with the factored weights; at $c = 1$ this is 19.4. For Ψ, apply the statement to the dual table (7.2), in which the window of B is read on the cobases and $c(B)$ is unchanged (7.12, 7.13). □

Proposition 19.7 (The freedom of the factorization). *As stated.*

Proof. By 19.4 the bases of the level $d(B)$ are the sets $X \sqcup Y$ with $X \in \mathcal{B}/R$ and $Y \in \mathcal{B}|R$, and those of the level $r(B)$ the sets $X \sqcup Y$ with $X \in \mathcal{B}|B$ and $Y \in \mathcal{B}/B$, every such set being a basis. Let $\theta_{X\sqcup Y} = \theta'_X\theta''_Y = \phi'_X\phi''_Y$ be two factorizations and fix a basis $X_d \sqcup Y_d$ of the level $d(B)$. For every pattern X of this level $X \sqcup Y_d$ is a basis, so $\phi'_X = \lambda_d\theta'_X$ with $\lambda_d = \theta''_{Y_d}/\phi''_{Y_d}$; for every room side Y of this level $X_d \sqcup Y$ is a basis, so $\phi''_Y = \theta'_{X_d}\theta''_Y/\phi'_{X_d} = \lambda_d^{-1}\theta''_Y$. Likewise at the level $r(B)$ with a constant λ_r. Conversely any $\lambda_d, \lambda_r > 0$ give a factorization, the patterns of the two levels having different sizes, and so have their room sides. The new factors multiply $K_{\mathcal{B}/R}$ and $\Psi_{\mathcal{B}/R}$ by λ_d, $K_{\mathcal{B}|B}$ and $\Psi_{\mathcal{B}|B}$ by λ_r, $K_{\mathcal{B}|R}$ and $\Psi_{\mathcal{B}|R}$ by λ_d^{-1}, and $K_{\mathcal{B}/B}$ and $\Psi_{\mathcal{B}/B}$ by λ_r^{-1}. With $c = \lambda_r/\lambda_d$,

$$\gamma_B^K = \frac{K_{\mathcal{B}|B}}{K_{\mathcal{B}/R}} \mapsto c\,\gamma_B^K, \quad \gamma_B^\Psi = \frac{\Psi_{\mathcal{B}/R}}{\Psi_{\mathcal{B}|B}} \mapsto c^{-1}\gamma_B^\Psi, \quad \gamma_R^K = \frac{K_{\mathcal{B}|R}}{K_{\mathcal{B}/B}} \mapsto c\,\gamma_R^K, \quad \gamma_R^\Psi = \frac{\Psi_{\mathcal{B}/B}}{\Psi_{\mathcal{B}|R}} \mapsto c^{-1}\gamma_R^\Psi,$$

so $\varrho_B = \gamma_B^\Psi/\gamma_B^K$ and $\varrho_R = \mathbf{E}_{\mathcal{B}/B}/\mathbf{E}_{\mathcal{B}|R} = \gamma_R^\Psi/\gamma_R^K$ are multiplied by c^{-2}, and γ_R^K/γ_B^K, $\gamma_R^\Psi/\gamma_B^\Psi$ and ϱ_B/ϱ_R are unchanged. □

Remark. The quotients γ_R^K/γ_B^K and $\gamma_R^\Psi/\gamma_B^\Psi$ are the Skeleton values of 19.5, which belong to the table and its gauge alone. What depends on the factorization is the split of a Skeleton value into a hinge value of the bunch and one of the room, and with it the cells, the cell families and the pooled families; the identities of the chapter hold at every factorization, each side changing with it.

Two lemmas are used below.

Lemma S8. *Let a bunch B of a table $(\mathcal{B},\theta)$ of rank r on $\mathcal{E}$, $n = |\mathcal{E}|$, have width one, the weights factoring across B and R. With $\alpha_B = \rho u$,*

$$\rho^{-d(B)}K(\rho u, \alpha_R) = K_{\mathcal{B}/R}(u)\,K_{\mathcal{B}|R}(\alpha_R) + \rho\,K_{\mathcal{B}|B}(u)\,K_{\mathcal{B}/B}(\alpha_R),$$

$$\rho^{-d^*(B)}\Psi(\rho u,\alpha_R)=\Psi_{\mathcal{B}|B}(u)\,\Psi_{\mathcal{B}/B}(\alpha_R)+\rho\,\Psi_{\mathcal{B}/R}(u)\,\Psi_{\mathcal{B}|R}(\alpha_R);$$

the cells have the ranks $r(B)=d(B)+1$ *and* $r-d(B)$ *and the letters*

$$K_{\mathcal{B}_B^+}=K_{\mathcal{B}/R}\,(\alpha_g+\gamma_B^K),\quad \Psi_{\mathcal{B}_B^+}=\Psi_{\mathcal{B}|B}\,(\alpha_g+\gamma_B^\Psi),$$
$$K_{\mathcal{B}_R^+}=K_{\mathcal{B}|R}+\alpha_g K_{\mathcal{B}/B},\quad \Psi_{\mathcal{B}_R^+}=\alpha_g\Psi_{\mathcal{B}|R}+\Psi_{\mathcal{B}/B};$$

and $d(B)+d(R)=r-1$, $d^*(B)+d^*(R)=n-r-1$. *For a family with masses* $\mathbf{m}$ *in which* B *has width one in every table,* $\kappa_B+\kappa_R=\kappa_{\mathcal{E}}+2\sigma$, σ *the total strength.*

Proof. By 19.4 the bases of the level $d(B)$ are the $X\sqcup Y$ with $X\in\mathcal{B}/R$, $Y\in\mathcal{B}|R$, and those of the level $r(B)=d(B)+1$ the $X\sqcup Y$ with $X\in\mathcal{B}|B$, $Y\in\mathcal{B}/B$, with $\theta_{X\sqcup Y}=\theta'_X\theta''_Y$ and the complement $(B\setminus X)\sqcup(R\setminus Y)$. Summing over the two levels, $K=K_{\mathcal{B}/R}K_{\mathcal{B}|R}+K_{\mathcal{B}|B}K_{\mathcal{B}/B}$ and $\Psi=\Psi_{\mathcal{B}/R}\Psi_{\mathcal{B}|R}+\Psi_{\mathcal{B}|B}\Psi_{\mathcal{B}/B}$, and on B the polynomials $K_{\mathcal{B}/R}$, $K_{\mathcal{B}|B}$, $\Psi_{\mathcal{B}|B}$, $\Psi_{\mathcal{B}/R}$ are homogeneous of the degrees $d(B)$, $d(B)+1$, $|B|-r(B)=d^*(B)$ and $|B|-d(B)=d^*(B)+1$. The deletions and the contractions of the hinge are $\mathcal{B}_B^+\setminus g=\mathcal{B}|B$, $\mathcal{B}_B^+/g=\mathcal{B}/R$, $\mathcal{B}_R^+\setminus g=\mathcal{B}|R$ and $\mathcal{B}_R^+/g=\mathcal{B}/B$ (19.4), which gives the ranks and, by 7.3 and 19.2, the letters. By 7.12, $d(S)=r-r(\mathcal{E}\setminus S)$, so $d(B)+d(R)=2r-r(B)-r(R)=r-c(B)=r-1$, and $d^*(B)+d^*(R)=n-r(B)-r(R)=n-r-1$. Table by table, $\kappa_B+\kappa_R=m_{\mathcal{E}}-\sum_j\big(s_j(r_j-1)+t_j(n-r_j-1)\big)=\kappa_{\mathcal{E}}+\sum_j(s_j+t_j)$. □

Lemma S9. *Let a family* F *on* $\mathcal{E}=B\sqcup R$, B *and* R *nonempty, have real data and be on its balance wall, and let* $f(\alpha)=\alpha^{\mathbf{m}-\mathbf{1}}\prod_j K_j(\alpha)^{-s_j}\Psi_j(\alpha)^{-t_j}$. *Then*

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t})=\int_{\Delta_R}\int_{\mathbb{R}^B_{>0}}f(x,v)\,dx\,d\omega_R(v)=\int_{\Delta_R}\int_{\Delta_B}\int_0^\infty\rho^{|B|-1}f(\rho u,v)\,d\rho\,d\omega_B(u)\,d\omega_R(v).$$

Proof. On the balance wall f is homogeneous of degree $\kappa_{\mathcal{E}}-n=-n$, $n=|\mathcal{E}|$. Let φ be the indicator of $[1,e]$, so that $\int_0^\infty\varphi(\lambda)\,d\lambda/\lambda=1$, and compute $I=\int_{\mathbb{R}^{\mathcal{E}}_{>0}}f(\alpha)\varphi(|\alpha_R|)\,d\alpha$ in two ways. With $\alpha=\lambda w$, $w\in\Delta_{\mathcal{E}}$, $d\alpha=\lambda^{n-1}d\lambda\,d\omega_{\mathcal{E}}(w)$ (2.7) and $f(\lambda w)=\lambda^{-n}f(w)$, so $I=\int_{\Delta_{\mathcal{E}}}f(w)\int_0^\infty\varphi(\lambda|w_R|)\frac{d\lambda}{\lambda}\,d\omega_{\mathcal{E}}(w)=\int_{\Delta_{\mathcal{E}}}f\,d\omega_{\mathcal{E}}=P_F$ (8.7). With $\alpha_R=\lambda v$, $v\in\Delta_R$, and $\alpha_B=\lambda x$, $x\in\mathbb{R}^B_{>0}$, $d\alpha=\lambda^{|R|-1}d\lambda\,d\omega_R(v)\,\lambda^{|B|}dx$ and $f(\lambda x,\lambda v)=\lambda^{-n}f(x,v)$, so $I=\int_0^\infty\varphi(\lambda)\frac{d\lambda}{\lambda}\int_{\Delta_R}\int_{\mathbb{R}^B_{>0}}f(x,v)\,dx\,d\omega_R(v)$, the first form. The second is 2.7 for $x=\rho u$. For $|B|=1$, Δ_B is a point with the Dirac measure (1.1(iii)). □

Theorem 19.9 (Walls glue). *As stated: (i) and (ii) for every family; in (iii) the identities for every family and the gluing when every active letter reads* B *alike.*

Proof. The gluing of the counts of one table, the counts of its cells,

$$d_{\mathcal{B}_B^+}(S_B)=d_{\mathcal{B}/R}(S_B),\quad d_{\mathcal{B}_B^+}(S_B+g)=d_{\mathcal{B}|B}(S_B),$$
$$d^*_{\mathcal{B}_B^+}(S_B)=d^*_{\mathcal{B}|B}(S_B),\quad d^*_{\mathcal{B}_B^+}(S_B+g)=d^*_{\mathcal{B}/R}(S_B),$$
$$d_{\mathcal{B}_R^+}(S_R)=d_{\mathcal{B}/B}(S_R),\quad d_{\mathcal{B}_R^+}(S_R+g)=d_{\mathcal{B}|R}(S_R),$$
$$d^*_{\mathcal{B}_R^+}(S_R)=d^*_{\mathcal{B}|R}(S_R),\quad d^*_{\mathcal{B}_R^+}(S_R+g)=d^*_{\mathcal{B}/B}(S_R),$$

and the inequalities $d_{\mathcal{B}/R}\le d_{\mathcal{B}|B}\le d_{\mathcal{B}/R}+1$ and $d^*_{\mathcal{B}|B}\le d^*_{\mathcal{B}/R}\le d^*_{\mathcal{B}|B}+1$ on the subsets of B, $d_{\mathcal{B}/B}\le d_{\mathcal{B}|R}\le d_{\mathcal{B}/B}+1$ and $d^*_{\mathcal{B}|R}\le d^*_{\mathcal{B}/B}\le d^*_{\mathcal{B}|R}+1$ on those of R, are the reference, proof of thm:wallsglue. For table j and $S=S_B\sqcup S_R$ call

$$a_j^K=d_{\mathcal{B}_j|B}(S_B)-d_{\mathcal{B}_j/R}(S_B),\quad b_j^K=d_{\mathcal{B}_j|R}(S_R)-d_{\mathcal{B}_j/B}(S_R),$$

$$a_j^\Psi = d^*_{\mathcal{B}_j/R}(S_B) - d^*_{\mathcal{B}_j|B}(S_B), \quad b_j^\Psi = d^*_{\mathcal{B}_j/B}(S_R) - d^*_{\mathcal{B}_j|R}(S_R),$$

all in $\{0,1\}$, in this proof the *jumps* of the letters K_j and Ψ_j on the side of the bunch and on the side of the room. The gluing of the counts reads

$$d_j(S) = d_{\mathcal{B}_j/R}(S_B) + d_{\mathcal{B}_j/B}(S_R) + \min(a_j^K, b_j^K), \qquad d_j^*(S) = d^*_{\mathcal{B}_j|B}(S_B) + d^*_{\mathcal{B}_j|R}(S_R) + \min(a_j^\Psi, b_j^\Psi).$$

At $S_B = \varnothing$ the jumps on the side of the bunch are 0, and at $S_R = \varnothing$ those on the side of the room. At $S_B = B$ those on the side of the bunch are 1: the ranks give $d_{\mathcal{B}_j|B}(B) = d_j(B) + 1$, $d_{\mathcal{B}_j/R}(B) = d_j(B)$, $d^*_{\mathcal{B}_j/R}(B) = |B| - d_j(B) = d_j^*(B) + 1$ and $d^*_{\mathcal{B}_j|B}(B) = d_j^*(B)$. At $S_R = R$ those on the side of the room are 1: $d_{\mathcal{B}_j|R}(R) = r_j - d_j(B) = d_{\mathcal{B}_j/B}(R) + 1$ and $d^*_{\mathcal{B}_j/B}(R) = |R| - r_j + d_j(B) + 1 = d^*_{\mathcal{B}_j|R}(R) + 1$.

(i) The tables of $F_{B\to g}(u)$ of index j have the bases of $\mathcal{B}^+_{j,R}$, at $(s_j, 0)$ and at $(0, t_j)$, so its wall at $S \subseteq R + g$ is $m'_S - \sum_j \big(s_j d_{\mathcal{B}^+_{j,R}}(S) + t_j d^*_{\mathcal{B}^+_{j,R}}(S)\big)$, $\mathbf{m}' = (\kappa_B, \mathbf{m}|_R)$. At $S = S_R$ the counts of the cell are $d_{\mathcal{B}_j/B}(S_R)$ and $d^*_{\mathcal{B}_j|R}(S_R)$, which are $d_j(S_R)$ and $d_j^*(S_R)$ by the gluing at $S_B = \varnothing$: the wall is κ_{S_R}. At $S = S_R + g$ they are $d_{\mathcal{B}_j|R}(S_R)$ and $d^*_{\mathcal{B}_j/B}(S_R)$, and the gluing at $S_B = B$ gives $d_j(B \sqcup S_R) = d_j(B) + d_{\mathcal{B}_j|R}(S_R)$ and $d_j^*(B \sqcup S_R) = d_j^*(B) + d^*_{\mathcal{B}_j/B}(S_R)$; with $\kappa_B = m_B - \sum_j (s_j d_j(B) + t_j d_j^*(B))$ the wall is $\kappa_{B\sqcup S_R}$.

(ii) With α_{S_B} replaced by $\varepsilon\alpha_{S_B}$, $K_{\mathcal{B}_j/R}$ is $\varepsilon^{d_{\mathcal{B}_j/R}(S_B)}$ times a polynomial positive at $\varepsilon = 0$ on the open orthant, its monomials having at least $d_{\mathcal{B}_j/R}(S_B)$ marks in S_B and some exactly that many (7.13); likewise $\Psi_{\mathcal{B}_j|B}$ with $d^*_{\mathcal{B}_j|B}(S_B)$. By the gluing at $S_R = \varnothing$ these are $d_j(S_B)$ and $d_j^*(S_B)$, so the exponent of the density at the face is κ_{S_B}.

(iii) The walls of G_B and G_R are read with the counts of the cells and the masses $(\mathbf{m}|_B, 2\sigma - \kappa_B)$ and $(\kappa_B, \mathbf{m}|_R)$. With

$$X = m_{S_B} + m_{S_R} - \sum_j \Big(s_j\big(d_{\mathcal{B}_j/R}(S_B) + d_{\mathcal{B}_j/B}(S_R)\big) + t_j\big(d^*_{\mathcal{B}_j|B}(S_B) + d^*_{\mathcal{B}_j|R}(S_R)\big)\Big),$$

the counts of the cells give $\kappa^{G_B}_{S_B} + \kappa^{G_R}_{S_R} = X$ and, the two hinge masses adding up to $2\sigma = \sum_j (s_j + t_j)$, $\kappa^{G_B}_{S_B+g} + \kappa^{G_R}_{S_R+g} = X + \sum_j \big(s_j(1 - a_j^K - b_j^K) + t_j(1 - a_j^\Psi - b_j^\Psi)\big)$, while $\kappa_{S_B\sqcup S_R} = X - \sum_j \big(s_j \min(a_j^K, b_j^K) + t_j \min(a_j^\Psi, b_j^\Psi)\big)$. Since $1 - a - b = (1 - \max(a,b)) - \min(a,b)$ for $a, b \in \{0,1\}$,

$$\begin{aligned}
\kappa^{G_B}_{S_B} + \kappa^{G_R}_{S_R} - \kappa_{S_B\sqcup S_R} &= \sum_j \big(s_j \min(a_j^K, b_j^K) + t_j \min(a_j^\Psi, b_j^\Psi)\big),\\
\kappa^{G_B}_{S_B+g} + \kappa^{G_R}_{S_R+g} - \kappa_{S_B\sqcup S_R} &= \sum_j \big(s_j(1 - \max(a_j^K, b_j^K)) + t_j(1 - \max(a_j^\Psi, b_j^\Psi))\big),
\end{aligned} \tag{50.1}$$

at all masses and exponents. At $S_R = \varnothing$ the first line gives $\kappa^{G_B}_{S_B} = \kappa_{S_B}$, the wall at the empty set being 0; at $S_B = \varnothing$ it gives $\kappa^{G_R}_{S_R} = \kappa_{S_R}$. The imbalance of G_B is

$$\kappa^{G_B}_{B+g} = m_B + 2\sigma - \kappa_B - \sum_j \big(s_j(d_j(B) + 1) + t_j(d_j^*(B) + 1)\big) = 2\sigma - \sum_j (s_j + t_j) = 0,$$

the cell $\mathcal{B}^+_{j,B}$ having rank $d_j(B) + 1$ on $|B| + 1 = d_j(B) + d_j^*(B) + 2$ marks: G_B is on its balance wall at all data. At $S_B = B$ the second line then gives $\kappa^{G_R}_{S_R+g} = \kappa_{B\sqcup S_R}$; at $S_R = R$ in particular

$\kappa^{G_R}_{R+g} = \kappa_{\mathcal{E}}$, so G_R is on its balance wall exactly when F is, and then the second line at $S_R = R$ gives $\kappa^{G_B}_{S_B+g} = \kappa_{S_B \sqcup R}$. These are the four identities.

Let now $s_j, t_j \geq 0$ and let every active letter read B alike. The jump of a letter on the side of the bunch at S_B is the order to which its hinge value vanishes at the face $u_{S_B} = 0$: by the expansion in (ii) applied to $\mathcal{B}_j|B$ and $\mathcal{B}_j/R$, with $\varepsilon\alpha_{S_B}$ for α_{S_B}, $\gamma^K_{j,B} = K_{\mathcal{B}_j|B}/K_{\mathcal{B}_j/R}$ is $\varepsilon^{a^K_j}$ times a function positive at $\varepsilon = 0$, and $\gamma^\Psi_{j,B} = \Psi_{\mathcal{B}_j/R}/\Psi_{\mathcal{B}_j|B}$ is $\varepsilon^{a^\Psi_j}$ times one. Constant multiples of one function vanish to one order at each face, so at S_B the active letters have one jump $a \in \{0, 1\}$ on the side of the bunch. If $a = 0$ every term of the first line of (50.1) vanishes, a letter of exponent zero contributing nothing; if $a = 1$ every term of the second does. Both lines are nonnegative, the exponents being nonnegative, so $\kappa_{S_B \sqcup S_R}$ is the smaller of the two sums. One active letter reads B alike by itself.

Positivity. If both cell families have every proper wall positive, let $S = S_B \sqcup S_R$ be nonempty and proper. In the first sum a nonempty part is a proper subset of the marks of its cell family, $S_B \subseteq B \subsetneq B + g$ and $S_R \subseteq R \subsetneq R + g$, and an empty part has the wall 0: the first sum is positive. In the second both $S_B + g$ and $S_R + g$ are nonempty, and at most one of them is all the marks of its cell family, S being proper, its wall then being the imbalance 0: the second sum is positive. So $\kappa_S > 0$. Conversely, by the identities, $\kappa^{G_B}_{S_B} = \kappa_{S_B}$ for $\varnothing \neq S_B \subseteq B$ and $\kappa^{G_B}_{S_B+g} = \kappa_{S_B \sqcup R}$ for $S_B \subsetneq B$ are proper walls of F, and likewise for G_R; this direction does not use the hypothesis. □

Remark. Without the reading alike, (iii) keeps the identities and loses the gluing. On $\mathcal{E} = \{1, 2, 3, 4\}$ with $B = \{1, 2\}$, the family of the lists $\binom{\mathcal{E}}{3}$ and $\binom{\mathcal{E}}{1}$, each at $(0, 1)$, has B of width one in both tables, with the cells $\binom{\{1,2,g\}}{2}$, $\binom{\{3,4,g\}}{2}$ and $\binom{\{1,2,g\}}{1}$, $\binom{\{3,4,g\}}{1}$, and the hinge values $\gamma^\Psi_{1,B} = \alpha_1 + \alpha_2$ and $\gamma^\Psi_{2,B} = \alpha_1\alpha_2/(\alpha_1 + \alpha_2)$, which are not constant multiples of one function. At the masses $(\frac{2}{5}, \frac{8}{5}, \frac{2}{5}, \frac{8}{5})$, on the balance wall, $\kappa_B = 1$ and both cell families have every proper wall positive, the least being $\frac{2}{5}$, while $\kappa_{\{1,3\}} = \frac{2}{5} + \frac{2}{5} - 1 = -\frac{1}{5}$, against $\frac{4}{5}$ from the gluing; the walls at $\{1, 4\}$, $\{2, 3\}$ and $\{2, 4\}$ do not glue either. In exact rational arithmetic (receipt `check_walls.py`): this family; the four identities at every subset at two partial leans of the same tables, where four walls do not glue; and the gluing at every subset for two tables sharing one weighted cell of the bunch at cobasis full leans, three pairs of exponents and three sets of masses, for a table at $(s, 0)$ with the cell $\binom{\{1,2,g\}}{1}$ together with a table at $(0, t)$ with the cell $\binom{\{1,2,g\}}{2}$, whose hinge values $\gamma^K_{1,B}$ and $\gamma^\Psi_{2,B}$ are both $\alpha_1 + \alpha_2$, and for $\binom{\mathcal{E}}{2}$ with B three of its four marks at two partial leans, where $\varrho_B = 1$.

Theorem 19.10 (Pooling factors at one hinge value). *As stated: at real exponents of any sign, every active letter having the one hinge value γ.*

Proof. The walls $\kappa_{\{e\}}$ at the singletons are positive and the exponents real, so the masses are real, and the integrals below are of positive functions.

Bounds. κ_B and κ_R are proper walls of F, hence positive, and $\kappa_B + \kappa_R = 2\sigma$ on the balance wall (Lemma S8): $0 < \kappa_B < 2\sigma$.

The cell families. By the identities of 19.9(iii), which hold for every family on the balance wall, G_B and G_R are on their balance walls and each of their proper walls is a proper wall of F, hence positive; their periods converge (8.7).

The family. Put $\phi(u) = u^{\mathbf{m}|_B - \mathbf{1}} \prod_j K_{\mathcal{B}_j/R}(u)^{-s_j} \Psi_{\mathcal{B}_j|B}(u)^{-t_j}$ on Δ_B. By 19.4, with $K_{\mathcal{B}_j/R}(\rho u) = \rho^{d_j(B)} K_{\mathcal{B}_j/R}(u)$, $\Psi_{\mathcal{B}_j|B}(\rho u) = \rho^{d^*_j(B)} \Psi_{\mathcal{B}_j|B}(u)$ and the hinge values homogeneous of degree one, Lemma S9 gives

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t}) = \int_{\Delta_B} \phi(u) \int_{\Delta_R} \int_0^\infty \rho^{\kappa_B-1} v^{\mathbf{m}|_R-\mathbf{1}} \times \prod_j K_{\mathcal{B}^+_{j,R}}\big(\rho\gamma^K_{j,B}(u),v\big)^{-s_j} \Psi_{\mathcal{B}^+_{j,R}}\big(\rho\gamma^\Psi_{j,B}(u),v\big)^{-t_j} d\rho\, d\omega_R(v)\, d\omega_B(u),$$

the powers of ρ collecting to $\rho^{m_B-1-\sum_j(s_jd_j(B)+t_jd_j^*(B))} = \rho^{\kappa_B-1}$. Every active letter has the hinge value $\gamma(u)$, and a letter of exponent zero is the factor 1. The substitution $x = \rho\gamma(u)$ at fixed u, $\rho^{\kappa_B-1}d\rho = \gamma(u)^{-\kappa_B}x^{\kappa_B-1}dx$, and Lemma S9 for G_R on $\{g\}\sqcup R$ at the masses $(\kappa_B, \mathbf{m}|_R)$ give

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t}) = P_{G_R}\big((\kappa_B,\mathbf{m}|_R);\mathbf{s},\mathbf{t}\big) \int_{\Delta_B} \phi(u)\,\gamma(u)^{-\kappa_B}\, d\omega_B(u).$$

The cell family of the bunch. By Lemma S8, with y the variable of g, $K_{\mathcal{B}^+_{j,B}}(u,y) = K_{\mathcal{B}_j/R}(u)\big(y+\gamma^K_{j,B}(u)\big)$ and $\Psi_{\mathcal{B}^+_{j,B}}(u,y) = \Psi_{\mathcal{B}_j|B}(u)\big(y+\gamma^\Psi_{j,B}(u)\big)$; every active letter has the factor $y+\gamma(u)$, and the exponents of the active letters add up to $\sum_j(s_j+t_j) = 2\sigma$. Lemma S9 for G_B on $\{g\}\sqcup B$ at the masses $(\mathbf{m}|_B, 2\sigma-\kappa_B)$, and the integral of a linear letter (the paragraph after 15.1, with $c_0=\gamma(u)$, $c_1=1$ and $0<2\sigma-\kappa_B<2\sigma$), give

$$P_{G_B}\big((\mathbf{m}|_B,2\sigma-\kappa_B);\mathbf{s},\mathbf{t}\big) = \int_{\Delta_B}\phi(u)\int_0^\infty y^{2\sigma-\kappa_B-1}\big(y+\gamma(u)\big)^{-2\sigma}dy\,d\omega_B(u) = \Gamma_{\!1}^{\!2}\!\left[\begin{matrix}\kappa_B,\ 2\sigma-\kappa_B\\ 2\sigma\end{matrix}\right]\int_{\Delta_B}\phi(u)\,\gamma(u)^{-\kappa_B}\,d\omega_B(u).$$

Multiplying the display for P_F by $\Gamma_{\!1}^{\!2}\!\left[\begin{matrix}\kappa_B,\ 2\sigma-\kappa_B\\ 2\sigma\end{matrix}\right]$ gives the statement, every factor being finite and positive. The parenthesis of the statement is 19.2: the constants λ_d, λ_r of table j multiply $\gamma^K_{j,B}$ by c and $\gamma^\Psi_{j,B}$ by c^{-1}, so a table with one active letter is normalized by its own constant; at full leans of all tables only the hinge values of different tables are compared; one table with both letters active and ϱ_B constant is normalized by $c = \varrho_B^{1/2}$, and $\gamma^K_B = \gamma^\Psi_B$ forces $\varrho_B = 1$. One table at $(0,t)$ has $s=0$ and $2\sigma = t$, and at $(s,0)$, $2\sigma = s$. □

Remark. One table at $(0,t)$ has the one active letter Ψ, whose hinge value γ^Ψ_B serves as γ at any factorization; the cell families are the cells $(\mathcal{B}^+_B,\theta')$ and $(\mathcal{B}^+_R,\theta'')$ at $(0,t)$, and the display is that of the reference, $\Gamma_{\!1}^{\!2}\!\left[\begin{matrix}\kappa_B,\ t-\kappa_B\\ t\end{matrix}\right] P_F(\mathbf{m};0,t) = P_{\mathcal{B}^+_B}\big((\mathbf{m}|_B,t-\kappa_B);0,t\big)P_{\mathcal{B}^+_R}\big((\kappa_B,\mathbf{m}|_R);0,t\big)$; at $(s,0)$ the same holds with $\gamma = \gamma^K_B$ and s for t. The proof above is the proof of the reference with γ^Ψ_B replaced by the common hinge value of the active letters. A family at full leans, every table at $(s_j,0)$ or $(0,t_j)$, has one active letter in each table, normalized by the factorization of its table; the hypothesis then asks only that the hinge values of the active letters of different tables be constant multiples of one another, a condition across the tables, and 22.6 is the same condition at every cell of a core. One table with $s,t>0$ has both letters active; the hypothesis is ϱ_B constant, reached at the factorization with $\varrho_B = 1$, and the display then holds at every pair (s,t) with $2\sigma = s+t$, the separation of 19.12 completed by the Beta corner of the hinge.

Proposition 19.11 (Pooling a realization). *As stated, for every family and every realization.*

Proof. The masses of Υ are $\tau_e = \sum_j\big(s_j\alpha_e\partial_e\log K_j(\alpha) + t_j\alpha_e\partial_e\log\Psi_j(\alpha)\big)$ (9.1). With $u = \alpha_B/|\alpha_B|$ fixed, the tables of index j of $F_{B\to g}(u)$, read as one table with two systems of weights, have the

letters $K^u_j(\alpha_g,\alpha_R)=K_{\mathcal{B}^+_{j,R}}(\gamma^K_{j,B}(u)\alpha_g,\alpha_R)$ and $\Psi^u_j(\alpha_g,\alpha_R)=\Psi_{\mathcal{B}^+_{j,R}}(\gamma^\Psi_{j,B}(u)\alpha_g,\alpha_R)$ (19.8). By 19.4 and the homogeneity of the hinge values, $\gamma^K_{j,B}(\alpha_B)=\rho\gamma^K_{j,B}(u)$ with $\rho=|\alpha_B|$, and

$$K_j(\alpha)=K_{\mathcal{B}_j/R}(\alpha_B)\,K^u_j(\rho,\alpha_R),\qquad \Psi_j(\alpha)=\Psi_{\mathcal{B}_j|B}(\alpha_B)\,\Psi^u_j(\rho,\alpha_R).$$

For $e\in R$ the first factors do not depend on α_e, so τ_e is the usage of e in $F_{B\to g}(u)$ at the gauge (ρ,α_R) with the exponents (s_j,t_j). Summing over $e\in B$, Euler's identity gives $\sum_{e\in B}\alpha_e\partial_e\log K_{\mathcal{B}_j/R}(\alpha_B)=d_j(B)$ and $\sum_{e\in B}\alpha_e\partial_e\log\Psi_{\mathcal{B}_j|B}(\alpha_B)=d^*_j(B)$, and, $\gamma^K_{j,B}$ being homogeneous of degree one,

$$\sum_{e\in B}\alpha_e\partial_e\log K_{\mathcal{B}^+_{j,R}}\big(\gamma^K_{j,B}(\alpha_B),\alpha_R\big)=\big[y\partial_y\log K_{\mathcal{B}^+_{j,R}}(y,\alpha_R)\big]_{y=\gamma^K_{j,B}(\alpha_B)}$$
$$=\big[\alpha_g\partial_{\alpha_g}\log K^u_j(\alpha_g,\alpha_R)\big]_{\alpha_g=\rho},$$

and likewise for Ψ. So $\tau_B=\sum_j\big(s_jd_j(B)+t_jd^*_j(B)\big)+\tau^u_g$, with τ^u_g the usage of g in $F_{B\to g}(u)$ at (ρ,α_R), and τ^u_g is the wall κ_B at the masses $\boldsymbol{\tau}$. The exponents are those of a realization and (ρ,α_R) is a gauge, so $((s_j,t_j)_j;(\rho,\alpha_R))$ is a realization of $F_{B\to g}(u)$ with these masses, its usage. For one table at $(0,t)$, $\Psi^u(\rho,\alpha_R)=\Psi_{\mathcal{B}^+_R}(\gamma^\Psi_B(\alpha_B),\alpha_R)$, so the usage of $(\mathcal{B}^+_R,\theta'')$ at $(0,t)$ and at the gauge $(\gamma^\Psi_B(\alpha_B),\alpha_R)$ is $\boldsymbol{\tau}|_R$ on R and, by the chain rule above, $\tau_B-t\,d^*(B)$ at g. □

Remark. The reference is one list at $(0,t)$, its last sentence. In exact rational arithmetic (receipt `check_classes_realization.py`): two tables on five marks, each the two-sum of a weighted cell of the bunch on $\{1,2,g\}$ and a weighted cell of the room on $\{3,4,5,g\}$, at the partial leans $(\frac{2}{3},\frac{5}{4})$ and $(3,\frac{1}{2})$ and a rational gauge; the usage of $F_{B\to g}(u)$ at $(|\alpha_B|,\alpha_R)$ is $(\kappa_B(\boldsymbol{\tau}),\boldsymbol{\tau}|_R)$.

Proposition 19.12 (Hinge values that agree). *As stated, for families.*

Proof. As in the proof of 19.10, with $\phi(u)=u^{\mathbf{m}|_B-\mathbf{1}}\prod_j K_{\mathcal{B}_j/R}(u)^{-s_j}\Psi_{\mathcal{B}_j|B}(u)^{-t_j}$,

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t})=\int_{\Delta_B}\phi(u)\int_{\Delta_R}\int_0^\infty\rho^{\kappa_B-1}v^{\mathbf{m}|_R-\mathbf{1}}$$
$$\times\prod_j K_{\mathcal{B}^+_{j,R}}\big(\rho\gamma^K_{j,B}(u),v\big)^{-s_j}\Psi_{\mathcal{B}^+_{j,R}}\big(\rho\gamma^\Psi_{j,B}(u),v\big)^{-t_j}d\rho\,d\omega_R(v)\,d\omega_B(u).$$

For $s_j\neq0$, $K_{\mathcal{B}^+_{j,R}}(\rho c_j\gamma(u),v)=K_{\mathcal{B}|R}(v)+\rho c_j\gamma(u)K_{\mathcal{B}/B}(v)$ is the letter K of $\mathcal{B}^+_{j,R}$ with its weights multiplied by c_j on its bases through g, read at $(\rho\gamma(u),v)$; for $t_j\neq0$, $\Psi_{\mathcal{B}^+_{j,R}}(\rho c^*_j\gamma(u),v)$ is the letter Ψ of $\mathcal{B}^+_{j,R}$ with its weights multiplied by c^*_j on its bases avoiding g, read at $(\rho\gamma(u),v)$ (Lemma S8). These are the letters of $G^{\mathbf{c}}_R$, and the letters of exponent zero are the factor 1. The substitution $x=\rho\gamma(u)$ and Lemma S9 for $G^{\mathbf{c}}_R$, which has the bases and so the walls of G_R and is on its balance wall by 19.9(iii), give the display. Its period converges, each proper wall of G_R being a proper wall of F, so the shape integral is finite.

For one table with ϱ_B constant, 19.7 reaches $\varrho_B=1$ by $c=\varrho_B^{1/2}$; then $\gamma^K_B=\gamma^\Psi_B$, $c=c^*=1$ with $\gamma=\gamma^K_B$, and $G^{\mathbf{c}}_R$ is the cell $(\mathcal{B}^+_R,\theta'')$ at (s,t), which is the reference. □

Theorem 19.13 (Gluing across a bunch of width one). *As stated: at nonnegative exponents, a letter of exponent zero being opened by nothing.*

Proof. The letters on the scale. For table j and $(u,v)\in\Delta_B\times\Delta_R$ put

$$A_j^K=K_{\mathcal{B}_j/R}(u)K_{\mathcal{B}_j|R}(v),\quad C_j^K=K_{\mathcal{B}_j|B}(u)K_{\mathcal{B}_j/B}(v),$$
$$A_j^\Psi=\Psi_{\mathcal{B}_j|B}(u)\Psi_{\mathcal{B}_j/B}(v),\quad C_j^\Psi=\Psi_{\mathcal{B}_j/R}(u)\Psi_{\mathcal{B}_j|R}(v),$$

all positive, so that $\rho^{-d_j(B)}K_j(\rho u,v)=A_j^K+\rho C_j^K$ and $\rho^{-d_j^*(B)}\Psi_j(\rho u,v)=A_j^\Psi+\rho C_j^\Psi$ (Lemma S8). The minors of the level d sit in A_j^K and in C_j^Ψ, those of the level r in C_j^K and in A_j^Ψ.

The scale. By Lemma S9, the powers of ρ collecting to ρ^{κ_B-1},

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t})=\int_{\Delta_R}\int_{\Delta_B}u^{\mathbf{m}|_B-\mathbf{1}}v^{\mathbf{m}|_R-\mathbf{1}}\,I(u,v)\,d\omega_B(u)\,d\omega_R(v),$$
$$I(u,v)=\int_0^\infty\rho^{\kappa_B-1}\prod_{\ell=1}^{p}(A_\ell+\rho C_\ell)^{-w_\ell}d\rho,$$

where ℓ runs over the p active letters, with their exponents $w_\ell>0$ and their coefficients (A_ℓ,C_ℓ), a letter of exponent zero being the factor 1. Here $\sum_\ell w_\ell=\sum_j(s_j+t_j)=2\sigma$, and κ_B and $\kappa_R=2\sigma-\kappa_B$ (Lemma S8, $\kappa_{\mathcal{E}}=0$) are proper walls: $0<\kappa_B<2\sigma$.

Opening the scale. If $p=1$, the integral of a linear letter (the paragraph after 15.1) gives $I=\Gamma_{\!\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\left[\begin{smallmatrix}w_1-\kappa_B,\ \kappa_B\\ w_1\end{smallmatrix}\right]A_1^{\kappa_B-w_1}C_1^{-\kappa_B}$. If $p\ge2$, choose $c_\ell\in(0,w_\ell)$ for $\ell<p$ with $0<\kappa_B-\sum_{\ell<p}c_\ell<w_p$, possible as $0<\kappa_B<\sum_\ell w_\ell$, and open each letter $\ell<p$ by 4.4 with $k=2$ on the line $\operatorname{Re}x_\ell=c_\ell$:

$$(A_\ell+\rho C_\ell)^{-w_\ell}=\frac{1}{2\pi i}\int_{c_\ell+i\mathbb{R}}\Gamma_{\!\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\left[\begin{smallmatrix}w_\ell-x_\ell,\ x_\ell\\ w_\ell\end{smallmatrix}\right]A_\ell^{x_\ell-w_\ell}(\rho C_\ell)^{-x_\ell}\,dx_\ell.$$

The modulus of the integrand is its value at the real parts times the modulus of the stacked Gamma, which decays exponentially along the line (Stirling), and $\int_0^\infty\rho^{\kappa_B-\sum_{\ell<p}c_\ell-1}(A_p+\rho C_p)^{-w_p}d\rho$ is finite; so Fubini puts the integral over ρ inside, where the integral of a linear letter at the complex index $x_p=\kappa_B-\sum_{\ell<p}x_\ell$, $0<\operatorname{Re}x_p<w_p$, gives $\Gamma_{\!\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\left[\begin{smallmatrix}w_p-x_p,\ x_p\\ w_p\end{smallmatrix}\right]A_p^{x_p-w_p}C_p^{-x_p}$. Hence

$$I(u,v)=\frac{1}{(2\pi i)^{p-1}}\int_{c_1+i\mathbb{R}}\cdots\int_{c_{p-1}+i\mathbb{R}}\prod_{\ell=1}^{p}\Gamma_{\!\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\left[\begin{smallmatrix}w_\ell-x_\ell,\ x_\ell\\ w_\ell\end{smallmatrix}\right]A_\ell^{x_\ell-w_\ell}C_\ell^{-x_\ell}\,dx_1\cdots dx_{p-1},$$
$$x_p=\kappa_B-\sum_{\ell<p}x_\ell,$$

the share integral $\int_{x_1+\cdots+x_p=\kappa_B}$ of 4.1: the factor $(2\pi i)^{-1}$ of each of the $p-1$ openings is its normalization $(2\pi i)^{1-p}$, and its dimension is $p-1$. At $p=1$ the share integral has dimension zero, one share and the pin $P=(1)$, and 4.1 gives the value of the integrand at the one admissible point $x_1=\kappa_B$: the formula for $p=1$ above.

The level shares. For the letter K_j write $x_\ell=a_j^r$ and $w_\ell-x_\ell=a_j^d$, for Ψ_j write $x_\ell=b_j^d$ and $w_\ell-x_\ell=b_j^r$, and give the letters of exponent zero the shares 0. The pin $\sum_\ell x_\ell=\kappa_B$ is $\sum_j(a_j^r+b_j^d)=\kappa_B$; the factor of K_j is $\Gamma_{\!\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\left[\begin{smallmatrix}a_j^d,\ a_j^r\\ s_j\end{smallmatrix}\right](A_j^K)^{-a_j^d}(C_j^K)^{-a_j^r}$ and that of Ψ_j is $\Gamma_{\!\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\left[\begin{smallmatrix}b_j^d,\ b_j^r\\ t_j\end{smallmatrix}\right](C_j^\Psi)^{-b_j^d}(A_j^\Psi)^{-b_j^r}$. The product of the powers over all letters, times $u^{\mathbf{m}|_B-\mathbf{1}}v^{\mathbf{m}|_R-\mathbf{1}}$, is $f(u)\,g(v)$, with

$$f(u)=u^{\mathbf{m}|_B-\mathbf{1}}\prod_j K_{\mathcal{B}_j/R}^{-a_j^d}\Psi_{\mathcal{B}_j/R}^{-b_j^d}K_{\mathcal{B}_j|B}^{-a_j^r}\Psi_{\mathcal{B}_j|B}^{-b_j^r},\qquad g(v)=v^{\mathbf{m}|_R-\mathbf{1}}\prod_j K_{\mathcal{B}_j|R}^{-a_j^d}\Psi_{\mathcal{B}_j|R}^{-b_j^d}K_{\mathcal{B}_j/B}^{-a_j^r}\Psi_{\mathcal{B}_j/B}^{-b_j^r},$$

the integrands of the periods of $F^{\mathrm{bunch}}(\mathbf{a},\mathbf{b})$ on Δ_B and of $F^{\mathrm{room}}(\mathbf{a},\mathbf{b})$ on Δ_R (8.7).

Balance on the pin. The tables $\mathcal{B}_j/R$ and $\mathcal{B}_j|B$ on B have the ranks $d_j(B)$ and $d_j(B)+1$, and $\mathcal{B}_j|R$ and $\mathcal{B}_j/B$ on R the ranks $r_j-d_j(B)$ and $r_j-d_j(B)-1$. With $a_j^d+a_j^r=s_j$, $b_j^d+b_j^r=t_j$ and $|B|-d_j(B)-1=d_j^*(B)$, the imbalance of $F^{\mathrm{bunch}}(\mathbf{a},\mathbf{b})$ at $\mathbf{m}|_B$ is

$$m_B-\sum_j\big(a_j^d d_j(B)+b_j^d(|B|-d_j(B))+a_j^r(d_j(B)+1)+b_j^r d_j^*(B)\big)=\kappa_B-\sum_j(a_j^r+b_j^d);$$

with $|R|+1-r_j+d_j(B)=n-r_j-d_j^*(B)$, that of $F^{\mathrm{room}}(\mathbf{a},\mathbf{b})$ at $\mathbf{m}|_R$ is

$$m_R-\sum_j\big(s_j(r_j-d_j(B))+t_j(|R|+1-r_j+d_j(B))\big)+\sum_j(a_j^r+b_j^d)=\kappa_{\mathcal{E}}-\kappa_B+\sum_j(a_j^r+b_j^d).$$

Both vanish on the pin, F being on its balance wall.

Fubini. On a contour of the statement the modulus of $f(u)g(v)$ is $f(u)g(v)$ at the real parts of the shares, which do not move along the contour, and its integral over $\Delta_B\times\Delta_R$ is the product of the two periods at the real parts, finite by hypothesis; the stacked Gammas decay exponentially along the contour. So Fubini exchanges the share integral with the integral over $\Delta_B\times\Delta_R$, and the inner integrals are $P_{F^{\mathrm{bunch}}(\mathbf{a},\mathbf{b})}(\mathbf{m}|_B;\mathbf{a},\mathbf{b})$ and $P_{F^{\mathrm{room}}(\mathbf{a},\mathbf{b})}(\mathbf{m}|_R;\mathbf{a},\mathbf{b})$: the general display.

Pair coordinates. When every s_j and t_j is positive, $p=2N$ and the shares are $(a_j^r,b_j^d)_j$. With $a_j^d=\sigma_j^d+\delta_j^d$, $b_j^d=\sigma_j^d-\delta_j^d$ and $a_j^r=s_j-a_j^d$, the affine map $(\sigma_j^d,\delta_j^d)_j\mapsto(a_j^r,b_j^d)_j$ has in each table the linear part $(y_\sigma,y_\delta)\mapsto(-y_\sigma-y_\delta,\ y_\sigma-y_\delta)$, of determinant 2. So the imaginary parts $\mathbf{y}$ of the shares and $\mathbf{y}'$ of the pair coordinates have $d\mathbf{y}=2^N d\mathbf{y}'$ and $\sum_\ell y_\ell=-2\sum_j y'_{\delta,j}$, and with $\operatorname{Im}\kappa_B=0$ and $\delta^1(-2z)=\frac12\delta^1(z)$, 4.1 gives

$$\int_{\sum_\ell x_\ell=\kappa_B}h=(2\pi)^{1-2N}\int_{\mathbb{R}^{2N}}h\,\delta^1\Big(\sum_\ell y_\ell\Big)d\mathbf{y}=2^{N-1}(2\pi)^{1-2N}\int_{\mathbb{R}^{2N}}h\,\delta^1\Big(\sum_j y'_{\delta,j}\Big)d\mathbf{y}',$$

2^{N-1} times the fibre integral in the pair coordinates pinned by $\sum_j\delta_j^d=\frac12(\sum_j s_j-\kappa_B)$, the image of the pin $\sum_j(a_j^r+b_j^d)=\sum_j(s_j-2\delta_j^d)=\kappa_B$, the admissible real points corresponding under the map. With $\Gamma_{\substack2\\1}\begin{bmatrix}a_j^d,\ a_j^r\\ s_j\end{bmatrix}\Gamma_{\substack2\\1}\begin{bmatrix}b_j^d,\ b_j^r\\ t_j\end{bmatrix}=\Gamma_{\substack4\\2}\begin{bmatrix}a_j^d,\ b_j^d,\ a_j^r,\ b_j^r\\ s_j,\ t_j\end{bmatrix}$ this is the first display, whose N coordinates σ_j^d are not pinned. For one table the pin fixes δ^d, $2^{N-1}=1$, and the fibre integral is $(2\pi)^{-1}\int dy=(2\pi i)^{-1}\int d\sigma^d$ along the line in σ^d. The other forms of the pin, the value $2\delta^d=s-\kappa_B=\delta(1+\varepsilon(B))-\mu_B$ (8.2(iii) with $c(B)=1$) and the swap of B and R are the reference, proof of thm:twosides. □

Remark. The first display needs both letters of every table active: a letter of exponent zero would put $\Gamma(0)$ into the stacked Gamma of its table. The general display carries one Beta corner $\Gamma_{\substack2\\1}\begin{bmatrix}\cdot,\ \cdot\\ w\end{bmatrix}$ for each active letter, and at a full lean of one table it has no free share, which is 19.14.

Corollary 19.14 (One Skeleton value pins the share). *As stated: real exponents of any sign, one Skeleton value for all active letters.*

Proof. $0<\kappa_B<2\sigma$ as in the proof of 19.10. With the coefficients of the proof of 19.13, Lemma S9 gives, all functions being positive,

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t}) = \int_{\Delta_R}\int_{\Delta_B} u^{\mathbf{m}|_B-\mathbf{1}}v^{\mathbf{m}|_R-\mathbf{1}} \times \int_0^\infty \rho^{\kappa_B-1}\prod_j (A_j^K+\rho C_j^K)^{-s_j}(A_j^\Psi+\rho C_j^\Psi)^{-t_j}\,d\rho\,d\omega_B(u)\,d\omega_R(v).$$

The Skeleton values are $A_j^K/C_j^K=\gamma_{j,R}^K(v)/\gamma_{j,B}^K(u)$ and $A_j^\Psi/C_j^\Psi=\gamma_{j,R}^\Psi(v)/\gamma_{j,B}^\Psi(u)$ (19.5), and by the hypothesis, the constants cancelling, every active letter has $A_\ell=\xi C_\ell$ with $\xi=\gamma_R(v)/\gamma(u)$. The exponents of the active letters add up to 2σ, so the integral of a linear letter gives $\int_0^\infty \rho^{\kappa_B-1}(\xi+\rho)^{-2\sigma}d\rho = \Gamma_{\!1}^{\!2}\!\left[\begin{matrix}\kappa_B,\ 2\sigma-\kappa_B\\ 2\sigma\end{matrix}\right]\xi^{\kappa_B-2\sigma}$, and

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t}) = \Gamma_{\!1}^{\!2}\!\left[\begin{matrix}\kappa_B,\ 2\sigma-\kappa_B\\ 2\sigma\end{matrix}\right]\int_{\Delta_R}\int_{\Delta_B} u^{\mathbf{m}|_B-\mathbf{1}}v^{\mathbf{m}|_R-\mathbf{1}} \times \prod_{s_j\neq 0}(C_j^K)^{-s_j}\prod_{t_j\neq 0}(C_j^\Psi)^{-t_j}\,\xi^{\kappa_B-2\sigma}\,d\omega_B(u)\,d\omega_R(v).$$

For level shares as in the statement, $(A_j^K)^{-a_j^d}(C_j^K)^{-a_j^r} = (C_j^K)^{-s_j}\xi^{-a_j^d}$ for an active K_j, $(A_j^\Psi)^{-b_j^r}(C_j^\Psi)^{-b_j^d} = (C_j^\Psi)^{-t_j}\xi^{-b_j^r}$ for an active Ψ_j, and an inactive letter contributes 1; since $\sum_j(a_j^d+b_j^r)=2\sigma-\sum_j(a_j^r+b_j^d)=2\sigma-\kappa_B$, the integrand above is $f(u)g(v)$ with f and g the integrands of the periods of $F^{\mathrm{bunch}}(\mathbf{a},\mathbf{b})$ and $F^{\mathrm{room}}(\mathbf{a},\mathbf{b})$ (proof of 19.13), whatever the shares. At complex shares $|f(u)g(v)|$ is $f(u)g(v)$ at the real parts, which satisfy the same constraints; its integral is finite by the display at the real parts, and both factors are positive, so $|f|$ and $|g|$ are integrable and Fubini gives the statement, the product of the two periods not depending on the shares. With one active letter the hypothesis holds with γ and γ_R its hinge values of B and of R. One table at $(0,t)$: $\mathbf{a}=0$, $b^d+b^r=t$ and $b^d=\kappa_B$, so the level shares are $(0,\kappa_B,0,t-\kappa_B)$ and the two families have the forms of the statement; at $(s,0)$, $a^r=\kappa_B$ and $a^d=s-\kappa_B$. □

Remark. The reference, rem:pinnedproduct, is one table at a full lean, the case of one active letter. The hypothesis does not depend on the factorizations: a change of the factorization of table j multiplies the hinge values of a letter of table j at B and at R by one constant (19.2), so the Skeleton values are unchanged.

Lemma 19.15 (Slopes and the range of the ratios). *As stated: for every table of a family, both letters of every table active.*

Proof. With $a_j^\ell=\sigma_j^\ell+\delta_j^\ell$ and $b_j^\ell=\sigma_j^\ell-\delta_j^\ell$, $K^{-a}\Psi^{-b}=\mathbf{E}^{-\sigma}(K/\Psi)^{-\delta}$ for every minor, $\mathbf{E}=K\Psi$. So the factors of table j in the word of the bunch family (proof of 19.13) are

$$\mathbf{E}_{\mathcal{B}_j/R}^{-\sigma_j^d}\mathbf{E}_{\mathcal{B}_j|B}^{-\sigma_j^r}\Big(\frac{K_{\mathcal{B}_j/R}}{\Psi_{\mathcal{B}_j/R}}\Big)^{-\delta_j^d}\Big(\frac{K_{\mathcal{B}_j|B}}{\Psi_{\mathcal{B}_j|B}}\Big)^{-\delta_j^r},\qquad \mathbf{E}_{\mathcal{B}_j/R}^{-\sigma_j^d}\mathbf{E}_{\mathcal{B}_j|B}^{-\sigma_j+\sigma_j^d}=\varrho_{j,B}^{-\sigma_j^d}\mathbf{E}_{\mathcal{B}_j|B}^{-\sigma_j},$$

and in the word of the room family $\mathbf{E}_{\mathcal{B}_j|R}^{-\sigma_j^d}\mathbf{E}_{\mathcal{B}_j/B}^{-\sigma_j+\sigma_j^d}=\varrho_{j,R}^{\sigma_j^d}\mathbf{E}_{\mathcal{B}_j/B}^{-\sigma_j}$ (19.2), the other factors not involving σ_j^d at fixed δ_j^d: σ_j^d enters through $\varrho_{j,B}(u)^{-\sigma_j^d}\varrho_{j,R}(v)^{\sigma_j^d}$.

Slopes. The wall at $S\subseteq B$ of the bunch family is $m_S-\sum_j\big(a_j^d d_{\mathcal{B}_j/R}(S)+b_j^d d^*_{\mathcal{B}_j/R}(S)+a_j^r d_{\mathcal{B}_j|B}(S)+b_j^r d^*_{\mathcal{B}_j|B}(S)\big)$, affine in the shares; raising σ_j^d by one at fixed δ_j^d raises a_j^d,b_j^d and lowers a_j^r,b_j^r by one, so the slope is $c_{\mathcal{B}_j/R}(S)-c_{\mathcal{B}_j|B}(S)$, $c=|S|-d-d^*$. With r^+ the rank function

of $\mathcal{B}^+_{j,B}$, $\mathcal{B}_j|B = \mathcal{B}^+_{j,B} \setminus g$ has the rank function r^+ on B and $\mathcal{B}_j/R = \mathcal{B}^+_{j,B}/g$ the rank function $Z \mapsto r^+(Z+g) - 1$, and $c_Z(S) = r_Z(S) + r_Z(B \setminus S) - r_Z(B)$ for a table Z on B (7.12, 7.13); the difference is the first displayed slope. On R the table of the level d is $\mathcal{B}_j|R = \mathcal{B}^+_{j,R} \setminus g$ and that of the level r is $\mathcal{B}_j/B = \mathcal{B}^+_{j,R}/g$, which gives the second.

Range. On the sector of an order of B, $\alpha_{\pi(1)} = \rho_0$ and $\alpha_{\pi(k)} = \rho_0 q_2 \cdots q_k$ with $q_k \in (0,1]$ and tails U_k, the letters of a table Z on B are $K_Z = \rho_0^{r_Z} \prod_k q_k^{d_Z(U_k)} k_{Z,\pi}$ and $\Psi_Z = \rho_0^{|B|-r_Z} \prod_k q_k^{d^*_Z(U_k)} \psi_{Z,\pi}$, with sector letters positive on the closed cube (8.5(ii)), hence between positive constants. So

$$\varrho_{j,B} = \frac{\mathbf{E}_{\mathcal{B}_j/R}}{\mathbf{E}_{\mathcal{B}_j|B}} = \prod_k q_k^{c_{\mathcal{B}_j|B}(U_k) - c_{\mathcal{B}_j/R}(U_k)} \times (\text{a function between positive constants}),$$

the exponent of q_k being minus the slope of U_k. Every nonempty proper subset of B is a tail of some order, the q_k range over $(0,1]$ independently, and finitely many sectors cover Δ_B: $\varrho_{j,B}$ is bounded exactly when no slope on B is positive (a positive slope at a tail U_k sends it to ∞ as $q_k \to 0$), and bounded below by a positive constant exactly when none is negative. On R, $\varrho_{j,R} = \mathbf{E}_{\mathcal{B}_j/B}/\mathbf{E}_{\mathcal{B}_j|R}$ carries q_k to the power of the slope of U_k: $\inf \varrho_{j,R} > 0$ exactly when no slope on R is positive and $\sup \varrho_{j,R} < \infty$ exactly when none is negative. A wall falls as σ^d_j decreases, toward the level d, exactly when its slope is positive, which forces $\sup \varrho_{j,B} = \infty$ or $\inf \varrho_{j,R} = 0$, so $\sup \varrho_{j,B}/\inf \varrho_{j,R} = \infty$; toward the level r, a negative slope forces $\inf \varrho_{j,B}/\sup \varrho_{j,R} = 0$. A change of the factorization of table j multiplies $\varrho_{j,B}$ and $\varrho_{j,R}$ by one constant c^{-2} (19.7), which keeps the quotient, the finiteness of the suprema, the positivity of the infima and the two ratios; the slopes are counts. □

Proposition 19.24 (The same shares closed at the gauge). *As stated: at complex exponents and masses, with the bound in absolute value.*

Proof. At width one the letters on the scale are linear in ρ (Lemma S8), and divided by their values at $\rho = 1$ they are the Skeleton polynomials of the statement (19.16): with the coefficients of the proof of 19.13, $\pi_{j,d} = A^K_j/(A^K_j + C^K_j)$, $\pi_{j,r} = 1 - \pi_{j,d}$, $\pi^*_{j,r} = A^\Psi_j/(A^\Psi_j + C^\Psi_j)$ and $\pi^*_{j,d} = 1 - \pi^*_{j,r}$, the chances of the levels under the basis law and the cobasis law at (u,v), all in $(0,1)$. Each polynomial is $1-(1-x)\epsilon$ with a constant exceedance polynomial ϵ: $\pi_{j,r}$ for K_j and $\pi^*_{j,d}$ for Ψ_j on the bunch, and, read from the top of the scale, $\pi_{j,d}$ and $\pi^*_{j,r}$ on the room. In 15.9(ii) only $k = 0$ remains, $[x^k] \prod_i \epsilon_i^{n_i} = 0$ for $k > 0$, and the term of $\mathbf{n}$ is $\prod_i \frac{(w_i)_{n_i}}{n_i!} \epsilon_i^{n_i} \Gamma_2^1 \left[\begin{matrix} \kappa, & |\mathbf{n}| + 1 \\ \kappa + |\mathbf{n}| + 1 \end{matrix}\right]$; the two sectors of 15.9(i) give the display, of nonnegative terms for real data with $s_j, t_j \geq 0$. For complex exponents and masses with $\operatorname{Re} \kappa_B > 0$ and $\operatorname{Re} \kappa^{\text{top}}_B > 0$ the series converges absolutely to the same value (15.9, last sentence; 15.3 for the convergence of the scale integral). The bound: $|(w)_n| \leq (|w|)_n$; $\prod_j \pi_{j,r}^{n_j} \pi_{j,d}^{*\,n'_j} \leq \lambda_B^M$; $\left|\Gamma_2^1 \left[\begin{matrix} \kappa_B, & M+1 \\ \kappa_B + M + 1 \end{matrix}\right]\right| = \left| \int_0^1 x^{\kappa_B - 1}(1-x)^M dx \right| \leq \int_0^1 x^{\operatorname{Re} \kappa_B - 1} dx = 1/\operatorname{Re} \kappa_B$; and $\sum_{|\mathbf{n}|+|\mathbf{n}'|=M} \prod_j \frac{(|s_j|)_{n_j} (|t_j|)_{n'_j}}{n_j!\, n'_j!} = \frac{(\sum_j (|s_j| + |t_j|))_M}{M!}$, the coefficient of z^M in $\prod_j (1-z)^{-|s_j| - |t_j|}$. Likewise on the room with λ_R and $\operatorname{Re} \kappa^{\text{top}}_B$. The bounds are summable over M, $\sum_M \frac{(W)_M}{M!} \lambda^M = (1-\lambda)^{-W}$ for $\lambda < 1$. □

Proposition 19.33 (A loop or a coloop on the simplex). *As stated: a mark that is a loop or a coloop in every table of a family.*

Proof. In a table where e is a loop no basis contains e, so $K_j = K_{j,\backslash e}$ and $\Psi_j = \alpha_e \Psi_{j,\backslash e}$; where e is a coloop every basis contains e, so $K_j = \alpha_e K_{j,/e}$ and $\Psi_j = \Psi_{j,/e}$ (7.3). The letters of F' (15.16) are these minors, of the ranks $r'_j = r_j$ at a loop and $r_j - 1$ at a coloop on $n-1$ marks, so the family word is $\alpha_e^{-\sum_{\eta_j=+1} s_j - \sum_{\eta_j=-1} t_j} W'(\alpha_{\mathcal{E}-e})$, with W' the word of F', homogeneous of degree $\kappa' - m_{\mathcal{E}-e}$, κ' the imbalance of F' at $\mathbf{m}|_{\mathcal{E}-e}$. On $\Delta_{\mathcal{E}}$ put $u = (u_e, (1-u_e)v)$, $u_e \in (0,1)$, $v \in \Delta_{\mathcal{E}-e}$, so that $u^{\mathbf{m}-\mathbf{1}} d\omega_{\mathcal{E}}(u) = u_e^{m_e-1}(1-u_e)^{m_{\mathcal{E}-e}-1} du_e \, v^{\mathbf{m}|_{\mathcal{E}-e}-\mathbf{1}} d\omega_{\mathcal{E}-e}(v)$ (3.12). Then

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t}) = \int_0^1 u_e^{\nu_e-1}(1-u_e)^{\kappa'-1} du_e \; P_{F'}(\mathbf{m}|_{\mathcal{E}-e};\mathbf{s},\mathbf{t}), \qquad \nu_e = m_e - \sum_{\eta_j=+1} s_j - \sum_{\eta_j=-1} t_j,$$

for real data in $[0,\infty]$, and the integral over u_e is $\Gamma_{\substack{2\\1}}\begin{bmatrix}\nu_e, & \kappa'\\ \nu_e+\kappa' & \end{bmatrix}$ where $\nu_e, \kappa' > 0$. This ν_e is the wall $\kappa_{\{e\}}$, since $d_j(\{e\}) = 1$ and $d_j^*(\{e\}) = 0$ at a coloop and the reverse at a loop, and by 8.2(iii), with $c_j(\{e\}) = 0$ and $\varepsilon_j(\{e\}) = \eta_j$, it is $\mu_e - \sum_j \eta_j \delta_j$. The imbalance of F' is $m_{\mathcal{E}} - m_e - \sum_{\eta_j=+1} \big(s_j(r_j - 1) + t_j(n - r_j)\big) - \sum_{\eta_j=-1} \big(s_j r_j + t_j(n-1-r_j)\big) = \kappa_{\mathcal{E}} - \nu_e$, so $\nu_e + \kappa' = \kappa_{\mathcal{E}}$. Several such marks are removed one at a time, each keeping its kind in the minors, and the product of the Beta corners is $\Gamma_{\substack{k+1\\1}}\begin{bmatrix}(\nu_{e_i})_i, & \kappa'\\ \kappa_{\mathcal{E}} & \end{bmatrix}$, split by 3.12 as stated. On the balance wall $\kappa' = -\nu_e$, and ν_e and κ' are not both positive.

The set $S = \{e\}$ has $c_j(S) = 0$ in every table, as 16.17 asks; there $\kappa_{\{e\}} = \nu_e$ and, by 8.2(iii) and 7.13 ($c_j(\mathcal{E}-e) = c_j(\{e\}) = 0$, $\varepsilon_j(\mathcal{E}-e) = 2r_j - n - \eta_j$), $\kappa_{\mathcal{E}\backslash e} = \kappa_{\mathcal{E}} - \nu_e = \kappa'$. The integral of 16.17 over $\Delta_{\{e\}} \times \Delta_{\mathcal{E}-e}$, $\Delta_{\{e\}}$ the point $u_e = 1$ with the Dirac measure, is the integral over $\Delta_{\mathcal{E}-e}$ of $v^{\mathbf{m}|_{\mathcal{E}-e}-\mathbf{1}}$ times the family word at $(1,v)$, which is $W'(v)$: it is $P_{F'}(\mathbf{m}|_{\mathcal{E}-e};\mathbf{s},\mathbf{t})$, and the compound formula at $S = \{e\}$ is the display. □

Theorem 19.34 (Pooling is a move). *As stated: for tables with positive rational weights, and in (ii) whenever the active letters have one hinge value at rational factorizations.*

Proof. (i) is the reference, proof of thm:cleaningmove(i): the map $(\rho, u, \alpha_R) \mapsto (\rho u, \alpha_R)$ and its inverse are defined over $\mathbb{Q}$ whatever the weights, and the faces correspond as stated. After the change of variables the form is $\rho^{\kappa_B - 1}\phi(u)$ times the form of $F_{B\to g}(u)$ at the gauge (ρ, α_R) (proof of 19.8), with ϕ as in the proof of 19.10; its coefficients lie in the field of the weights and of the factors, which is $\mathbb{Q}$. The walls are matched by 19.9(i), (ii) and the gluing of the counts, for families.

(ii) The common hinge value γ is the hinge value of an active letter, a quotient of polynomials with rational coefficients, positive on the open simplex. The change $(\rho, u, \alpha_R) \mapsto (\rho\gamma(u), u, \alpha_R)$ is birational over $\mathbb{Q}$, with the inverse $(x, u, \alpha_R) \mapsto (x/\gamma(u), u, \alpha_R)$, and bijective on the open domain; by the proof of 19.10 it carries the form of (i) to the product of the form $\phi(u)\gamma(u)^{-\kappa_B} d\omega_B(u)$ of the shape and the form of G_R at the masses $(\kappa_B, \mathbf{m}|_R)$. In the datum of G_B, read on the section $|\alpha_B| = 1$ (Lemma S9), the change $y = \gamma(u)z$, birational over $\mathbb{Q}$ and bijective on the open domain, carries the form to $\phi(u)\gamma(u)^{-\kappa_B} d\omega_B(u)$ times $z^{2\sigma-\kappa_B-1}(1+z)^{-2\sigma} dz$, the form of the list on two marks whose bases are the two singletons, at the exponents $(0, 2\sigma)$ and the masses $(\kappa_B, 2\sigma - \kappa_B)$, read in its chart at the first mark, where its letter is $1 + z$. So the data of F and of that list, and the data of G_B and G_R, are related by these moves to the same product of three data, with rational masses κ_B and $2\sigma - \kappa_B$. If P_F converges, every proper wall of F is positive (8.7) and 19.10 gives the convergence of the periods of G_B and G_R, the Beta corner, and the shape integral, which is P_F over P_{G_R}; and P_F is the first integral of the chain. □

Remark. Positive rational weights that factor across B and R factor with rational factors: fix a basis $X_\ell \sqcup Y_\ell$ at each level $\ell \in \{d(B), r(B)\}$ and put $\theta'_X = \theta_{X\sqcup Y_\ell}$ and $\theta''_Y = \theta_{X_\ell\sqcup Y}/\theta_{X_\ell\sqcup Y_\ell}$ for the patterns X and the room sides Y of the level ℓ. For any factorization $\theta = \vartheta'\vartheta''$, $\theta_{X\sqcup Y_\ell}\theta_{X_\ell\sqcup Y}/\theta_{X_\ell\sqcup Y_\ell} = \vartheta'_X\vartheta''_{Y_\ell}\vartheta'_{X_\ell}\vartheta''_Y/(\vartheta'_{X_\ell}\vartheta''_{Y_\ell}) = \theta_{X\sqcup Y}$. The hypothesis of (ii) asks more, rational factors at which the active letters share one hinge value; for one table with both letters active it asks a rational factorization with $\varrho_B = 1$.

Proposition 19.37 (Cleaning commutes with maps). *As stated, for maps between any tables.*

Proof. A bijection g that carries $(\mathcal{B}, \theta)$ to $(\mathcal{B}_1, \theta_1)$ maps bases to bases with their weights. Parallel and series bunches, the counts and the widths are defined by the bases, so they are carried to those of the image; a factorization θ', θ'' across a class B is carried to $\theta'_{1,g(p)} = \theta'_p$, $\theta''_{1,g(Y)} = \theta''_Y$, a factorization across $g(B)$, and the minors of $g(B)$ are the images of those of B with their weights, so $\gamma^K_{g(B)}(\alpha\circ g^{-1}) = \gamma^K_B(\alpha)$ and likewise for Ψ. An exchange maps T to $\mathcal{E}_1 \setminus g(T)$, with the weight θ_T. A parallel bunch B has $|T \cap B| \le 1$ for every basis and no loop, so $g(B)$ has $|g(B) \cap T_1| \ge |B| - 1$ for every basis T_1 of the image and no coloop: a series bunch, and conversely. The patterns of $g(B)$ are the sets $g(B \setminus p)$, p a pattern of B, and putting $\theta'_{1,g(B\setminus p)} = \theta'_p$ and $\theta''_{1,g(R\setminus Y)} = \theta''_Y$ factors the weights of the image. The level of $g(B \setminus p)$ is $|B| - |p|$, so the restriction of the image to $g(B)$ has the patterns $g(B \setminus p)$, $p \in \mathcal{B}/R$, and its contraction of the room the patterns $g(B \setminus p)$, $p \in \mathcal{B}|B$; hence $K_{\mathcal{B}_1|g(B)}(\alpha \circ g^{-1}) = \sum_{p\in\mathcal{B}/R} \theta'_p \alpha^{B\setminus p} = \Psi_{\mathcal{B}/R}(\alpha)$ and $K_{\mathcal{B}_1/g(R)}(\alpha \circ g^{-1}) = \Psi_{\mathcal{B}|B}(\alpha)$, so the hinge value by K of $g(B)$ is γ^Ψ_B; likewise its hinge value by Ψ is γ^K_B. The statement on the cleanings of lists is the reference, proof of prop:cleanmaps. □

50.20 Chapter 20: words of a tree

Definition 20.2 (Side shape; half-sum and difference; pattern coefficients). As stated, for every table of a family.

Proof. The one claim is the identity $L_{j,w}(z) = \sum_p e^{\langle z_B, \chi_p\rangle} c_{j,p}(w; z_R)$. Theorem 12.7 for table j gives $\Lambda_j(z) = \sum_{p\subseteq B} e^{\langle z_B,\chi_p\rangle}\Lambda_{j,(p)}(z_R)$, with $\Lambda_{j,(p)} = 0$ off the patterns of table j. Replacing z by $-z$ gives

$$\Lambda_j(-z) = \sum_p e^{-\langle z_B,\chi_p\rangle}\Lambda_{j,(p)}(-z_R).$$

Since $\chi_{B\setminus p} = -\chi_p$ on B, the substitution $p \mapsto B \setminus p$ turns this into

$$\Lambda_j(-z) = \sum_p e^{\langle z_B,\chi_p\rangle}\Lambda_{j,(B\setminus p)}(-z_R) = \sum_p e^{\langle z_B,\chi_p\rangle}\Lambda^*_{j,(p)}(z_R).$$

So

$$w\Lambda_j(z) + (1-w)\Lambda_j(-z) = \sum_p e^{\langle z_B,\chi_p\rangle}\big(w\Lambda_{j,(p)}(z_R) + (1-w)\Lambda^*_{j,(p)}(z_R)\big).$$

□

Proposition 20.3 (The side shape, and what an exchange does to it). *As stated, for every table of a family and every bijection that carries or exchanges the family.*

Proof. For $T \subseteq \mathcal{E}$ and $z \in \mathbb{R}^{\mathcal{E}}$, with $(g^*z)_e = z_{g(e)}$,

$$\langle z, \chi_{g(T)} \rangle = \sum_{e \in \mathcal{E}} z_{g(e)}\, \chi_{g(T)}(g(e)) = \sum_{e \in \mathcal{E}} (g^*z)_e\, \chi_T(e) = \langle g^*z, \chi_T \rangle.$$

If g carries F, then $g(\mathcal{B}_j) = \mathcal{B}_{h(j)}$ with $\theta_{h(j),g(T)} = \theta_{j,T}$ (Definition 11.13), so

$$\Lambda_{h(j)}(z) = \sum_{T \in \mathcal{B}_j} \theta_{j,T}\, e^{\langle z, \chi_{g(T)} \rangle} = \Lambda_j(g^*z),$$

and $\Lambda_{h(j)}(-z) = \Lambda_j(-g^*z)$, as g^* is linear; hence $L_{h(j),w}(z) = L_{j,w}(g^*z)$. If g exchanges F, then $T \mapsto \mathcal{E} \setminus g(T)$ maps $\mathcal{B}_j$ onto $\mathcal{B}_{h(j)}$ with $\theta_{h(j),\mathcal{E}\setminus g(T)} = \theta_{j,T}$, and $\chi_{\mathcal{E}\setminus g(T)} = -\chi_{g(T)}$, so $\Lambda_{h(j)}(z) = \Lambda_j(-g^*z)$ and $\Lambda_{h(j)}(-z) = \Lambda_j(g^*z)$; hence

$$L_{h(j),w}(z) = w\, \Lambda_j(-g^*z) + (1-w)\, \Lambda_j(g^*z) = L_{j,1-w}(g^*z).$$

The display holds for any two positive numbers a, b in place of $\Lambda_j(z), \Lambda_j(-z)$ and any $s_j, t_j > 0$: it is Theorem 3.2 at the unit configuration on a two-element set with the coarsest partition, whose Zamma is $(wa + (1-w)b)^{-(s_j+t_j)} = \mathsf{Z}_{s_j+t_j;(1)}(wa + (1-w)b)$ at the shape $(w, 1-w)$, that is, the two-factor form $a^{-s_j} b^{-t_j} = \Gamma_{\frac{1}{2}}\begin{bmatrix} s_j + t_j \\ s_j,\ t_j \end{bmatrix} \int_0^1 w^{s_j-1}(1-w)^{t_j-1}(wa+(1-w)b)^{-s_j-t_j}\, dw$ (the reference, proof of prop:sideexchange). Taking $a = \Lambda_j(z)$ and $b = \Lambda_j(-z)$, $wa + (1-w)b = L_{j,w}(z)$.

For one table an exchange has h the identity, so that $L_w(z) = L_{1-w}(g^*z)$ for every w. Hence

$$\mathsf{Z}_{s+t;(1)}\big(L_w(g^*z)\big) = \mathsf{Z}_{s+t;(1)}\big(L_{1-w}(z)\big)\,:$$

the exchange together with $w \mapsto 1-w$ keeps the Zamma. The substitution $w \mapsto 1-w$ takes $w^{s-1}(1-w)^{t-1}$ to $w^{t-1}(1-w)^{s-1}$, which is the same function on $(0,1)$ exactly when $s = t$. □

Theorem 20.4 (The junction in pattern form). *As stated, for every family.*

Proof. The proof is that of the reference (proof of thm:junctionpattern), with a product over the tables in each step.

Signed coordinates. By Theorem 8.7 the period is the integral of $\alpha^{\mathbf{m}-\mathbf{1}} \prod_j K_j^{-s_j} \Psi_j^{-t_j}\, d\alpha$ over the section $\alpha_g = 1$. Put $\alpha = e^{2z}$, so that $d\alpha_e = 2\alpha_e\, dz_e$ for each of the $n-1$ marks $e \neq g$. Theorem 7.15(i) for each table gives $K_j(\alpha) = e^{\langle \mathbf{1}, z \rangle} \Lambda_j(z)$ and $\Psi_j(\alpha) = e^{\langle \mathbf{1}, z \rangle} \Lambda_j(-z)$, so, with $\sum_j (s_j + t_j) = 2\sigma$ and $\boldsymbol{\mu} = \mathbf{m} - \sigma\mathbf{1}$ (Definition 8.1),

$$\begin{aligned} \alpha^{\mathbf{m}} \prod_j K_j^{-s_j} \Psi_j^{-t_j} &= e^{2\langle \mathbf{m}, z \rangle - 2\sigma \langle \mathbf{1}, z \rangle} \prod_j \Lambda_j(z)^{-s_j} \Lambda_j(-z)^{-t_j} \\ &= e^{2\langle \boldsymbol{\mu}, z \rangle} \prod_j \Lambda_j(z)^{-s_j} \Lambda_j(-z)^{-t_j}, \end{aligned}$$

and, with $e^{2\langle \boldsymbol{\mu}, z \rangle} = e^{2\langle \boldsymbol{\mu}|_B, z_B \rangle} e^{2\langle \boldsymbol{\mu}|_R, z_R \rangle}$,

$$P_F(\mathbf{m}; \mathbf{s}, \mathbf{t}) = 2^{n-1} \int_{\mathbb{R}^{\mathcal{E}-g}} e^{2\langle \boldsymbol{\mu}, z \rangle} \prod_j \Lambda_j(z)^{-s_j} \Lambda_j(-z)^{-t_j}\, dz_{\mathcal{E}-g} \Big|_{z_g = 0}.$$

Side shapes. For j with $s_j, t_j > 0$, Proposition 20.3 writes the factor of table j as

$$\Lambda_j(z)^{-s_j} \Lambda_j(-z)^{-t_j} = \Gamma_{\frac{1}{2}}\begin{bmatrix} s_j + t_j \\ s_j,\ t_j \end{bmatrix} \int_0^1 w_j^{s_j-1}(1-w_j)^{t_j-1} L_{j,w_j}(z)^{-(s_j+t_j)}\, dw_j.$$

For $t_j = 0 < s_j$ the factor is $\Lambda_j(z)^{-s_j} = L_{j,1}(z)^{-s_j}$, for $s_j = 0 < t_j$ it is $\Lambda_j(-z)^{-t_j} = L_{j,0}(z)^{-t_j}$, and an inactive table contributes 1. So every active table contributes $L_{j,w_j}(z)^{-(s_j+t_j)}$, integrated over w_j when $s_j, t_j > 0$ and with the value of w_j fixed in the statement otherwise.

Scales. For each active j, $L_{j,w_j}(z) > 0$ and $L^{-a} = \Gamma(a)^{-1}\int_0^\infty y^{a-1}e^{-yL}dy$ with $a = s_j + t_j > 0$. The constants combine to $\Gamma_{\frac{1}{2}}\begin{bmatrix} s_j+t_j \\ s_j,\ t_j \end{bmatrix}\Gamma(s_j+t_j)^{-1} = \Gamma(s_j)^{-1}\Gamma(t_j)^{-1}$ when $s_j, t_j > 0$, and to $\Gamma(s_j)^{-1}$ or $\Gamma(t_j)^{-1}$ for a table at a full lean: the prefactor of the statement.

Patterns. By Definition 20.2,

$$\sum_{j \text{ active}} y_j L_{j,w_j}(z) = \sum_{p\subseteq B} e^{\langle z_B, \chi_p\rangle} C_p, \qquad C_p = \sum_{j \text{ active}} y_j\, c_{j,p}(w_j; z_R) \geq 0,$$

each $c_{j,p}(w; z_R)$ being a combination with the nonnegative coefficients w and $1-w$ of the nonnegative functions $\Lambda_{j,(p)}(z_R)$ and $\Lambda^*_{j,(p)}(z_R)$.

The Gramma. With $x = e^{z_B}$, Definition 2.1 in its logarithmic form gives

$$\int_{\mathbb{R}^B} e^{2\langle \boldsymbol{\mu}|_B, z_B\rangle} \exp\Big(-\sum_p C_p\, e^{\langle \chi_p, z_B\rangle}\Big) dz_B = \mathsf{G}_{2\boldsymbol{\mu}|_B;(\chi_p)_p}\big((C_p)_p\big),$$

the configuration having one column χ_p for each p with $C_p \neq 0$.

Order of integration. Every integrand is nonnegative, so Tonelli's theorem allows the integrals to be taken in the order of the statement: the side shapes outermost, then z_{R-g} at $z_g = 0$, then the scales y_j, then z_B. The two sides agree in $[0,\infty]$ and are finite, every proper wall being positive (Theorem 8.7). □

Remark. With one table the formula is that of the reference, and at a full lean of that table the integral over the side shape is absent, which is the reference's last sentence.

Proposition 20.5 (What a map keeping the bunch gives the coefficients). *As stated, for every family.*

Proof. Since $\tilde g$ keeps B, it maps R onto R, so $(\tilde g^* z)_R = \tilde g^*_R z_R$, and for $p \subseteq B$, substituting $e' = \tilde g(e)$,

$$\langle (\tilde g^* z)_B, \chi_p\rangle = \sum_{e\in B} z_{\tilde g(e)}\chi_p(e) = \sum_{e'\in B} z_{e'}\chi_{\tilde g(p)}(e') = \langle z_B, \chi_{\tilde g(p)}\rangle.$$

If $\tilde g$ carries F, Proposition 20.3 and Definition 20.2 give

$$\begin{aligned}\sum_{q\subseteq B} e^{\langle z_B,\chi_q\rangle} c_{h(j),q}(w; z_R) &= L_{h(j),w}(z) = L_{j,w}(\tilde g^* z)\\ &= \sum_{p\subseteq B} e^{\langle z_B, \chi_{\tilde g(p)}\rangle} c_{j,p}(w; \tilde g^*_R z_R).\end{aligned}$$

The vectors χ_q, $q \subseteq B$, are distinct, and at fixed z_R the exponentials $e^{\langle z_B,\chi_q\rangle}$ with distinct exponents are linearly independent functions of z_B: along a generic direction the largest exponent dominates (the reference, proof of prop:mapcoeff). Comparing the coefficients at $q = \tilde g(p)$ gives $c_{h(j),\tilde g(p)}(w; z_R) = c_{j,p}(w; \tilde g^*_R z_R)$. If $\tilde g$ exchanges F, the same comparison with $L_{h(j),w}(z) = L_{j,1-w}(\tilde g^* z)$ gives $c_{h(j),\tilde g(p)}(w; z_R) = c_{j,p}(1-w; \tilde g^*_R z_R)$ for every w, and $w \mapsto 1-w$ gives the statement. □

Proposition 20.6 (Level form of the half-sum). *As stated, for every table of the family of Theorem 20.4.*

Proof. Every claim concerns one table j, and the reference's proof (proof of prop:levelformQ) applies to it. The two displayed coefficients are $c_{j,p}(w;z_R)$ at $w=\frac12$ and its derivative in w (Definition 20.2).

(i) $c_{j,B\setminus p}(\frac12;-z_R) = \frac12\big(\Lambda_{j,(B\setminus p)}(-z_R)+\Lambda_{j,(p)}(z_R)\big) = c_{j,p}(\frac12;z_R)$, and $\partial_w c_{j,B\setminus p}(w;-z_R) = \Lambda_{j,(B\setminus p)}(-z_R)-\Lambda_{j,(p)}(z_R) = -\partial_w c_{j,p}(w;z_R)$.

(ii) Let τ be a transposition of two marks of B fixing the rest. As in the proof of Proposition 20.5, $L_{j,1/2}(\tau^*z)=\sum_p e^{\langle z_B,\chi_{\tau(p)}\rangle}c_{j,p}(\frac12;z_R)$. If $c_{j,p}(\frac12;\cdot)$ depends on $|p|$ alone, this is $L_{j,1/2}(z)$, since $|\tau(p)|=|p|$. Conversely, if $L_{j,1/2}(\tau^*z)=L_{j,1/2}(z)$ for every such τ, the independence of the exponentials gives $c_{j,\tau(p)}(\frac12;\cdot)=c_{j,p}(\frac12;\cdot)$, and these transpositions act transitively on the subsets of B of each size. So level form is the invariance of $L_{j,1/2}$ under these transpositions. Further,

$$L_{j,1/2}(z)=\tfrac12\sum_{T\in\mathcal{B}_j}\theta_{j,T}\big(e^{\langle z,\chi_T\rangle}+e^{\langle z,\chi_{\mathcal{E}\setminus T}\rangle}\big),$$
$$L_{j,1/2}(\tau^*z)=\tfrac12\sum_{T\in\mathcal{B}_j}\theta_{j,T}\big(e^{\langle z,\chi_{\tau(T)}\rangle}+e^{\langle z,\chi_{\mathcal{E}\setminus\tau(T)}\rangle}\big),$$

by the computation of the proof of Proposition 20.3. The exponentials $e^{\langle z,\chi_S\rangle}$, $S\subseteq\mathcal{E}$, are linearly independent, so the invariance under τ says that τ maps the multiset $\mathcal{B}_j\uplus\{\mathcal{E}\setminus T:\ T\in\mathcal{B}_j\}$, with its weights, onto itself. When $2r_j\neq n$ a basis and a complement of a basis have different sizes, τ keeps sizes, and the condition says that τ maps $\mathcal{B}_j$ onto itself with its weights, that is, carries table j (Definition 11.13), as in Proposition 14.12.

(iii) If τ carries table j, it keeps $\Lambda_j(z)$ and $\Lambda_j(-z)$ under $z\mapsto\tau^*z$; if it exchanges table j, it swaps them (Proposition 20.3, the bijection of the tables being the identity). Either way $L_{j,1/2}(\tau^*z)=L_{j,1/2}(z)$, so the half-sum has level form by (ii), and $\partial_w L_{j,w}(\tau^*z)=\pm\partial_w L_{j,w}(z)$, so the square of the difference is unchanged by τ. The transpositions of B generate the permutations of B. □

Theorem 20.11 (Building back up). *As stated; the last sentence of (iv) is stated for every molecule.*

Proof. Parts (i) to (iii), and (iv) up to its last sentence, are proved in the reference (proof of thm:buildup). The last sentence of (iv) makes three claims.

Dimension. In (iv) every table has $s_j,t_j>0$ and is active. The unknowns are the $c_{j,T}$, $T\in\mathcal{B}_j$, $\sum_j|\mathcal{B}_j|$ of them, subject to the N share sums $\sum_T c_{j,T}=t_j-s_j$ and the $n-1$ pins $-\frac12\sum_{j,T}c_{j,T}\chi_T(e)=\mu_e$, $e\in\mathcal{E}-g$. Their linear parts are independent. Indeed, let $\sum_j\lambda_j\sum_T c_{j,T}+\sum_{e\neq g}d_e\sum_{j,T}c_{j,T}\chi_T(e)$ vanish identically, and put $d_g=0$. The coefficient of $c_{j,T}$ is $\lambda_j+\langle d,\chi_T\rangle=\lambda_j+2\langle d,\mathbf{1}_T\rangle-\langle d,\mathbf{1}\rangle$, so $\langle d,\mathbf{1}_T\rangle$ is constant over the bases of every table. By Lemma 7.8, d is constant on every molecule; the family is a molecule, so d is constant, and $d_g=0$ makes it 0; then every $\lambda_j=0$. So the fibre of differences has dimension $\sum_j|\mathcal{B}_j|-N-(n-1)=\sum_j(|\mathcal{B}_j|-1)-(n-1)$.

The pins at the centre. At the centre $t_j=s_j$ and $\boldsymbol{\mu}=0$, so the share sums read $\sum_T c_{j,T}=0$. With $\chi_T=2\mathbf{1}_T-\mathbf{1}$,

$$\sum_T c_{j,T}\chi_T(e)=2\big(M_j^{\mathsf T}\mathbf{c}_j\big)_e-\sum_T c_{j,T},$$

so on the share sums the pin of $e \neq g$ reads $(\sum_j M_j^{\mathsf{T}} \mathbf{c}_j)_e = 0$. The equation at g follows, since $\sum_{e \in \mathcal{E}} (M_j^{\mathsf{T}} \mathbf{c}_j)_e = \sum_T c_{j,T} |T| = r_j \sum_T c_{j,T} = 0$. So the pins and the share sums together are equivalent to $\sum_T c_{j,T} = 0$ for every j and $\sum_j M_j^{\mathsf{T}} \mathbf{c}_j = 0$.

The contour. At the centre the gauge $\mathbf{1}$ is native (Proposition 8.21(i)). The leaves are opened by the atom formula with one share per basis and letter (Corollary 18.16), and the native split there (Definition 12.25) gives the basis T of table j the shares $a_{j,T} = s_j \theta_{j,T} / K_j(\mathbf{1})$ and $b_{j,T} = t_j \theta_{j,T} / \Psi_j(\mathbf{1})$, the probabilities of T under the basis law and the cobasis law at $\mathbf{1}$ times the exponents. As $\Psi_j(\mathbf{1}) = \sum_T \theta_{j,T} = K_j(\mathbf{1})$ and $s_j = t_j$, $c_{j,T} = b_{j,T} - a_{j,T} = 0$ there, so the wall contour of the native split (Theorem 18.13(iii)) is $\operatorname{Re} \mathbf{c} = 0$. □

Remark. With one table $\sum_T c_T = \frac{1}{r} \sum_e (M^{\mathsf{T}} \mathbf{c})_e$ follows from $M^{\mathsf{T}} \mathbf{c} = 0$, and the dimension is $|\mathcal{B}_1| - n$: the reference's case of one table at the centre.

Proposition 20.12 (The draw series). *As stated; the reading of its last part is stated for every family.*

Proof. The first part, through the Trailmoment and the Dirichlet moments, is the reference's proposition (proof of prop:jointdraw). For the last part take one block, $q = 2N$, $P_{2j-1} = K_j$ with the index s_j and $P_{2j} = \Psi_j$ with the index t_j; an index 0 contributes the factor 1.

Constants. K_j is homogeneous of degree r_j, with the squarefree monomials u^T, $T \in \mathcal{B}_j$, and the coefficients $\theta_{j,T}$. For $\mathbf{a} = \mathbf{1}_T$, $b_{\mathbf{a}} = r_j! / \prod_e a_e! = r_j!$, and every other $\mathbf{a}$ has $[u^{\mathbf{a}}] K_j = 0$; so $C_{2j-1} = \theta_{j,\max} / r_j!$. Likewise Ψ_j has degree $n - r_j$ and the monomials $u^{\mathcal{E} \setminus T}$ with the coefficients $\theta_{j,T}$, so $C_{2j} = \theta_{j,\max} / (n - r_j)!$.

The period. $\mathbb{E}_{U \sim \mathrm{Dir}_{\mathbf{m}}}[f(U)] = \Gamma_1^n \begin{bmatrix} \mathbf{m} \\ m_{\mathcal{E}} \end{bmatrix}^{-1} \int_{\Delta_{\mathcal{E}}} u^{\mathbf{m}-\mathbf{1}} f \, d\omega_{\mathcal{E}}$ for $f \geq 0$ (Theorem 3.9), so the left side times $\Gamma_1^n \begin{bmatrix} \mathbf{m} \\ m_{\mathcal{E}} \end{bmatrix}$ is the stated integral, which on the balance wall is $P_F(\mathbf{m}; \mathbf{s}, \mathbf{t})$ (Theorem 8.7).

The urn. For u in the simplex, $(\sum_e u_e)^g = \sum_{|\mathbf{a}|=g} \frac{g!}{\mathbf{a}!} u^{\mathbf{a}} = 1$ is the total chance of g independent draws from u, grouped by their counts $\mathbf{a}$. For $P_{2j-1} = K_j$,

$$\frac{P_{2j-1}}{C_{2j-1}} = \sum_{T \in \mathcal{B}_j} \frac{\theta_{j,T}}{\theta_{j,\max}} \, r_j! \, u^T$$

is the chance that a round of r_j draws is a basis T of table j and does not fail, a round that is the basis T failing with probability $1 - \theta_{j,T} / \theta_{j,\max}$; so $Q_{2j-1} = 1 - P_{2j-1} / C_{2j-1}$ is the chance that the round fails, and likewise Q_{2j} for a round of $n - r_j$ draws and the cobases. Given u, independent rounds all fail with the chance $\prod_i Q_i(u)^{k_i}$. The urn that draws a mark with probability proportional to its current mass and then adds one to that mass gives a sequence of draws with the counts $\mathbf{b}$ the chance $\prod_e (m_e)_{b_e} / (m_{\mathcal{E}})_{|\mathbf{b}|} = \mathbb{E}_{U \sim \mathrm{Dir}_{\mathbf{m}}}[U^{\mathbf{b}}]$ (Theorem 3.11), the chance of the same sequence when $U \sim \mathrm{Dir}_{\mathbf{m}}$ is drawn first and the marks are then drawn independently from U. Summing over the sequences whose rounds all fail, $\mathbb{E}_{U \sim \mathrm{Dir}_{\mathbf{m}}}[\prod_i Q_i(U)^{k_i}]$ is the urn's chance of the event of the statement; the order of the rounds does not change it, the product being symmetric in its factors. For lists every ratio $\theta_{j,T} / \theta_{j,\max}$ is 1, the Q_i have integer coefficients, and the expectation is a finite sum of Dirichlet moments.

Theorem 15.13(i). With the references $M_i = C_i$, on the simplex

$$M_i^{-w_i - n_i} (M_i - L_i)^{n_i} = C_i^{-w_i} (1 - L_i / C_i)^{n_i} = C_i^{-w_i} Q_i^{n_i},$$

so the series of Theorem 15.13(i), divided by $\Gamma_1^n \begin{bmatrix} \mathbf{m} \\ m_{\mathcal{E}} \end{bmatrix}$, is the present series term by term. □

Corollary 20.13 (At $\delta = 0$ and at a full lean the period reads the law of one letter for each table). *As stated, for every family.*

Proof. Letters. For a table riding the line, $K_j^{-\sigma_j}\Psi_j^{-\sigma_j} = \mathbf{E}_j^{-\sigma_j}$; at $(s_j, 0)$ the factor is $K_j^{-s_j}$ and at $(0, t_j)$ it is $\Psi_j^{-t_j}$. So on the open simplex

$$\prod_j K_j^{-s_j}\Psi_j^{-t_j} = \prod_j L_j^{-\nu_j} = \mathsf{Z}_{\boldsymbol{\nu};I_N}\big((L_j)_j\big),$$

the Zamma at the unit configuration being $\prod_j \xi_j^{-\nu_j}$ (Definition 2.12).

The period. By Theorem 8.7 and the Dirichlet density (Theorem 3.9),

$$\begin{aligned} P_F(\mathbf{m};\mathbf{s},\mathbf{t}) &= \int_{\Delta_\mathcal{E}} u^{\mathbf{m}-\mathbf{1}} \prod_j K_j^{-s_j}\Psi_j^{-t_j}\, d\omega_\mathcal{E} \\ &= \Gamma_1^n \begin{bmatrix} \mathbf{m} \\ m_\mathcal{E} \end{bmatrix} \mathbb{E}_{U\sim \mathrm{Dir}_\mathbf{m}}\Big[\mathsf{Z}_{\boldsymbol{\nu};I_N}\big((L_j(U))_j\big)\Big]. \end{aligned}$$

The expectation is the integral of the kernel against the image $\phi_\mathbf{m}$ of $\mathrm{Dir}_\mathbf{m}$ under $(L_j)_j$, the Trailmoment $(\mathsf{T}_{\boldsymbol{\nu};I_N}[\mathrm{id}]\,\phi_\mathbf{m})((0,\infty)^N)$ with the identity as coefficient function (Definition 5.1), as in the display of Theorem 18.1(i). With one table it is the Trailmoment $(\mathsf{T}_{\nu;(1)}[x]\,\phi_\mathbf{m})((0,\infty))$ of a law on the half-line, at $\delta = 0$ the image of $\mathrm{Dir}_\mathbf{m}$ under the even letter (Theorem 5.9).

The law. Each L_j is a polynomial, positive on the open simplex and continuous on the closed one, and $\mathrm{Dir}_\mathbf{m}$ charges only the open simplex; so $\phi_\mathbf{m}$ is carried by $\prod_j(0, \max_{\Delta_\mathcal{E}} L_j]$. A law carried by a compact set is determined by its moments, polynomials being dense in the continuous functions on that set. Every moment $\mathbb{E}[\prod_j L_j(U)^{k_j}]$ is the expectation of a polynomial in U, a finite sum of Dirichlet moments (Theorem 3.11). □

Theorem 20.14 (The draw series along a chain). *As stated, for every family of tables.*

Proof. The proof is that of the reference (proof of thm:drawchain), with the acceptances and a product over the tables.

The failures split. Fix table j and a round of r_j draws. A round that extends on S_{i+1} extends on S_i, with the trace $P_i = P_{i+1} \cap S_i$, and every round extends on $S_0 = \varnothing$ with the trace $\varnothing$. So the events A_i, that the round extends on S_i and is accepted at $S_1, \dots, S_i$, decrease with i, A_0 is certain, and $\mathfrak{f}_{j,i}$ is the chance of $A_i \setminus A_{i+1}$; hence $\sum_{i=0}^d \mathfrak{f}_{j,i} = 1 - \Pr(A_{d+1})$.

The acceptances telescope. A round extends on $S_{d+1} = \mathcal{E}$ exactly when it is a basis T of table j with distinct draws, which has the chance $r_j!\,u^T$; its traces are then $P_i = T \cap S_i$, and its acceptances multiply to

$$\prod_{i=0}^{d} \frac{\theta_j(S_{i+1}; T\cap S_{i+1})}{\theta_j(S_i; T\cap S_i)} = \frac{\theta_j(\mathcal{E};T)}{\theta_j(\varnothing;\varnothing)} = \frac{\theta_{j,T}}{\theta_{j,\max}}.$$

So $\Pr(A_{d+1}) = \sum_T r_j!\,u^T\theta_{j,T}/\theta_{j,\max} = r_j!\,K_j(u)/\theta_{j,\max}$. The cobasis rounds are the basis rounds of the dual table, whose bases $\mathcal{E}\setminus T$ carry the weights $\theta_{j,T}$, whose largest weight is $\theta_{j,\max}$ and whose basis polynomial is Ψ_j (Proposition 7.2); so $\sum_i \mathfrak{f}^*_{j,i} = 1 - (n-r_j)!\,\Psi_j/\theta_{j,\max}$.

Polynomials. Each $\mathfrak{f}_{j,i}(u)$ is a finite sum, over the sequences of r_j draws, of the monomial of the sequence times a product of acceptance and rejection probabilities in $[0,1]$: a polynomial with nonnegative coefficients, with integer coefficients for lists, whose rounds are always accepted.

The series. Proposition 20.12, with one block and the constants $C_{2j-1} = \theta_{j,\max}/r_j!$, $C_{2j} = \theta_{j,\max}/(n-r_j)!$ of its last part, gives

$$\mathbb{E}_{U\sim\mathrm{Dir}_{\mathbf{m}}}\Big[\prod_j K_j^{-s_j}\Psi_j^{-t_j}\Big] = \prod_j C_{2j-1}^{-s_j}C_{2j}^{-t_j}\sum_{\mathbf{k}\in\mathbb{N}^{2N}}\prod_j \frac{(s_j)_{k_{2j-1}}(t_j)_{k_{2j}}}{k_{2j-1}!\,k_{2j}!} \times \mathbb{E}_{U\sim\mathrm{Dir}_{\mathbf{m}}}\Big[\prod_j\Big(\sum_i \mathfrak{f}_{j,i}\Big)^{k_{2j-1}}\Big(\sum_i \mathfrak{f}^*_{j,i}\Big)^{k_{2j}}\Big],$$

both sides finite or infinite together. The multinomial theorem expands

$$\frac{(s_j)_k}{k!}\Big(\sum_i \mathfrak{f}_{j,i}\Big)^k = \sum_{|\mathbf{k}_j|=k}\frac{(s_j)_{|\mathbf{k}_j|}}{\mathbf{k}_j!}\prod_i \mathfrak{f}_{j,i}^{k_{j,i}},$$

with nonnegative terms, and likewise for the cobasis rounds; Tonelli's theorem exchanges the sums and the expectation, and multiplying by $\Gamma_1^n\begin{bmatrix}\mathbf{m}\\ m_{\mathcal{E}}\end{bmatrix}$ (Theorem 3.9) gives the display. Each expectation is that of a polynomial with nonnegative coefficients, a finite nonnegative combination of Dirichlet moments (Theorem 3.11).

Nesting. $\sum_{i'\ge i} k_{j,i'}$ is a tail sum of nonnegative integers, so it decreases with i.

Bijections. Let g keep each B_i, hence each S_i, and the masses. A sequence of draws D from u has the chance of the sequence $g(D)$ from g_*u. If g maps the bases of table j onto those of table $h(j)$ with their weights, then $g(T\cap S_i) = g(T)\cap S_i$, so D extends on S_i for table j exactly when $g(D)$ extends on S_i for table $h(j)$, the traces corresponding under g, and $\theta_j(S_i;P) = \theta_{h(j)}(S_i;g(P))$, so the acceptances agree: $\mathfrak{f}_{h(j),i}(g_*u) = \mathfrak{f}_{j,i}(u)$, and likewise for the cobasis rounds, g carrying the dual tables as well. If $T\mapsto \mathcal{E}\setminus g(T)$ maps the bases of table j onto those of table $h(j)$ with their weights, then $g(T)$ is a cobasis of table $h(j)$ for every basis T of table j, the round lengths agree, $r_j = n - r_{h(j)}$, the largest weights over the traces agree in the same way, and $\mathfrak{f}^*_{h(j),i}(g_*u) = \mathfrak{f}_{j,i}(u)$, $\mathfrak{f}_{h(j),i}(g_*u) = \mathfrak{f}^*_{j,i}(u)$. Since the masses are kept, $g_*U\sim\mathrm{Dir}_{\mathbf{m}}$ when $U\sim\mathrm{Dir}_{\mathbf{m}}$, so in the second case

$$\mathbb{E}\Big[\prod_{j,i}\mathfrak{f}_{j,i}(U)^{k_{j,i}}\mathfrak{f}^*_{j,i}(U)^{l_{j,i}}\Big] = \mathbb{E}\Big[\prod_{j,i}\mathfrak{f}^*_{h(j),i}(U)^{k_{j,i}}\mathfrak{f}_{h(j),i}(U)^{l_{j,i}}\Big],$$

the expectation at the indices $(\mathbf{k}'_{j'},\mathbf{l}'_{j'}) = (\mathbf{l}_{h^{-1}(j')},\mathbf{k}_{h^{-1}(j')})$. With one table h is the identity, an exchange maps the bases onto complements of bases, so $r = n-r$, and the array is symmetric under $\mathbf{k}\leftrightarrow\mathbf{l}$. □

Theorem 20.15 (The draw series along a tree). *As stated, for every molecule whose children's weights factor across the childcules.*

Proof. The proof is that of the reference (proof of thm:drawtree), the weights entering through the acceptances; the coordinates of the tree and their independence (Theorem 3.12 at every node) are unchanged.

(i) Let $\mathcal{B}'$ have rank r' at the node v, and write $R_i = R_{v,i}$, $x = x^{(v)}$, $u = u^{(v)}$ and $v^{(i)}$ for the shape of R_i. By Proposition 7.9 the bases of $\mathcal{B}'$ are the sets $T = p\sqcup\bigsqcup_i X_i$, p a pattern at B_v and X_i a basis of $\mathcal{B}'_{(p)}|R_i$ of size $r'_{p,i}$, and by the hypothesis $\theta_T = \prod_i \theta_{(p),i}(X_i)$. The shape of M_v is $x_{B_v}u$ on B_v and $x_{R_i}v^{(i)}$ on R_i, so by homogeneity

$$K_{\mathcal{B}'} = \sum_p x_{B_v}^{|p|}u^p\prod_i x_{R_i}^{r'_{p,i}}K_{\mathcal{B}'_{(p)}|R_i}\big(v^{(i)}\big),$$

the restrictions carrying the weights $\theta_{(p),i}$. Multiply by $r'!/\theta_{\max}(\mathcal{B}')$, write $r'! = \frac{r'!}{\prod_i r'_{p,i}!}\prod_i r'_{p,i}!$, and multiply and divide the term of p by

$$\prod_i \theta_{\max}\big(\mathcal{B}'_{(p)}|R_i\big);$$

this gives $\mathfrak{s}_{\mathcal{B}'} = \sum_p \mathfrak{p}_{\mathcal{B}',p}\prod_i \mathfrak{s}_{\mathcal{B}'_{(p)}|R_i}$. The hypothesis fixes the weights of the restrictions up to constant factors whose product is 1, which change neither the $\mathfrak{s}$ of the restrictions nor the first factor of $\mathfrak{p}_{\mathcal{B}',p}$. That factor is at most 1, since

$$\theta_{\max}(\mathcal{B}') = \max_p \max_{(X_i)_i}\prod_i \theta_{(p),i}(X_i) = \max_p \prod_i \theta_{\max}\big(\mathcal{B}'_{(p)}|R_i\big).$$

The chance that r' independent draws from the shape of M_v are the basis T with distinct draws is $r'!$ times its monomial, and the acceptance with probability $\theta_T/\theta_{\max}(\mathcal{B}')$ gives the chance $r'!K_{\mathcal{B}'}/\theta_{\max}(\mathcal{B}')$ of an accepted basis. The round passes v showing p, its draws in B_v being the marks of p and its numbers of draws in the R_i the $r'_{p,i}$, with the chance $\frac{r'!}{\prod_i r'_{p,i}!}x_{B_v}^{|p|}u^p\prod_i x_{R_i}^{r'_{p,i}}$, and given this its draws in R_i are $r'_{p,i}$ independent draws from $v^{(i)}$. The acceptance splits as

$$\frac{\theta_T}{\theta_{\max}(\mathcal{B}')} = \frac{\prod_i \theta_{\max}\big(\mathcal{B}'_{(p)}|R_i\big)}{\theta_{\max}(\mathcal{B}')}\ \prod_i \frac{\theta_{(p),i}(X_i)}{\theta_{\max}\big(\mathcal{B}'_{(p)}|R_i\big)},$$

an acceptance at v followed by independent acceptances in the childcules. So $\mathfrak{p}_{\mathcal{B}',p}$ is the chance of passing v showing p and being accepted there, and $\mathfrak{s}_{\mathcal{B}'_{(p)}|R_i}$ the chance of an accepted basis of the restriction in R_i.

(ii) By (i) the round fails at v with the chance $1-\sum_p \mathfrak{p}_{\mathcal{B}',p}$, and otherwise passes v showing one pattern p and is accepted there; it then first fails at w in the subtree of R_i exactly when it succeeds in $R_1,\dots,R_{i-1}$ and first fails at w inside R_i, which is the recursion. Write $\mathfrak{p}_{\mathcal{B}',p} = a_p\,\mathfrak{p}^\circ_{\mathcal{B}',p}$ with $a_p \le 1$ the first factor. Then

$$1-\sum_p \mathfrak{p}_{\mathcal{B}',p} = \Big(1-\sum_p \mathfrak{p}^\circ_{\mathcal{B}',p}\Big) + \sum_p (1-a_p)\,\mathfrak{p}^\circ_{\mathcal{B}',p}.$$

The bracket is $1 = (x_{B_v}\sum_{e\in B_v}u_e + \sum_i x_{R_i})^{r'}$, expanded by the multinomial theorem, less some of its terms, distinct patterns giving distinct terms (the reference, proof of thm:drawtree, part (ii)); it has nonnegative coefficients in the coordinates of v, and so has the sum. With $1-\prod_i S_i = \sum_i \prod_{i'<i} S_{i'}(1-S_i)$ and induction on the subtree, every $\mathfrak{f}_{\mathcal{B}'\to w}$ is a finite sum of products, over the blocks of the tree, of polynomials with nonnegative coefficients in one block each.

(iii) On the simplex $r_j!K_j/\theta_{j,\max} = \mathfrak{s}_{\mathcal{B}_j} = 1-\sum_w \mathfrak{f}_{j,w}$, with the sum in $[0,1)$ on the interior. The letter Ψ_j is the basis polynomial of the dual table (Proposition 7.2), whose bases $\mathcal{E}\setminus T$ carry the weights $\theta_{j,T}$, so that its largest weight is $\theta_{j,\max}$; its children are the duals of the children with the same weights (Lemma 14.7(ii) with the identity), and the dual of a direct sum is the direct sum of the duals of its parts with the product weights, so the factoring passes to the dual and (i), (ii) apply to its rounds. Then $K_j^{-s_j} = (r_j!/\theta_{j,\max})^{s_j}(1-\sum_w \mathfrak{f}_{j,w})^{-s_j}$, expanded as in Proposition 20.12 and by the multinomial theorem as in Theorem 20.14, with nonnegative terms; Tonelli's theorem, the independence of the blocks under $\mathrm{Dir}_{\mathbf{m}}$ (Theorem 3.12) and Theorem 3.11 give the series and the form of its expectations. On the balance wall the left side is the period (Theorem 8.7).

(iv) A round that first fails in the subtree of w passes every node above w, which gives the nesting. On a chain every node has one childcule. The table at the node M_k that a round of table j reaches is the child of table j at its trace P_k on S_k, whose largest weight is $\theta_j(S_k;P_k)$ in the notation of Theorem 20.14; so the first factor of $\mathfrak{p}$ at that node is $\theta_j(S_{k+1};P_{k+1})/\theta_j(S_k;P_k)$, the acceptance at S_{k+1}, and passing the node is extending on S_{k+1}. The chances $\mathfrak{f}$ of the two theorems agree, and the series is that of Theorem 20.14. □

Proposition 20.17 (Rates at the centre). *As stated, for every family whose active tables are connected.*

Proof. (i) is Proposition 8.21(ii), with $c_j(\mathcal{E}\setminus S)=c_j(S)$ (Theorem 7.13).

(ii) The rate is $\varpi=\min_i\varpi_i$ over the letters, ϖ_i the least of $\kappa_S/d_i(S)$ over the nonempty proper S with $d_i(S)>0$ (Theorem 15.13(ii)); an inactive table has $\sigma_j=0$ and no letters. A connected table has $c_j(S)\geq 1$ on every nonempty proper S (Definition 8.1), and so no loops and no coloops, a loop or a coloop e having $c_j(\{e\})=r_j(\{e\})-d_j(\{e\})=0$ (Theorem 7.13) with $\{e\}$ proper as $n\geq 3$. So $\kappa_S=\sum_j\sigma_j c_j(S)\geq\sum_j\sigma_j=\sigma$.

For the letter K_j, $d_j(S)=|S|-r_j^*(S)=r_j-r_j(\mathcal{E}\setminus S)\leq r_j-1$ (Definition 7.12), as $\mathcal{E}\setminus S$ is nonempty and contains no loop. For Ψ_j, $d_j^*(S)=|S|-r_j(S)$ is the nullity of S, which increases with the set, and $S\subseteq\mathcal{E}-e$ for some e, of nullity $n-1-r_j(\mathcal{E}-e)=n-1-r_j$, as e is not a coloop. So $\kappa_S/d_j(S)\geq\sigma/(r_j-1)$ wherever $d_j(S)>0$, and $\kappa_S/d_j^*(S)\geq\sigma/(n-r_j-1)$ wherever $d_j^*(S)>0$.

At $S=\mathcal{E}-e$, every table without loops or coloops has $c_j(\mathcal{E}-e)=c_j(\{e\})=r_j(\{e\})-d_j(\{e\})=1$ (Theorem 7.13), so $\kappa_{\mathcal{E}-e}=\sigma$; and $d_j(\mathcal{E}-e)=r_j-r_j(\{e\})=r_j-1$, $d_j^*(\mathcal{E}-e)=n-1-r_j$. Hence $\varpi_{K_j}=\sigma/(r_j-1)$ when $r_j\geq 2$ and $\varpi_{\Psi_j}=\sigma/(n-r_j-1)$ when $n-r_j\geq 2$, attained at the faces $\mathcal{E}-e$; a letter with no S of positive count does not enter the minimum. As $(r_j-1)+(n-r_j-1)=n-2\geq 1$, at least one letter of every active table enters, and $\varpi=\sigma/\max_j\max(r_j-1,n-r_j-1)$.

(iii) By Definition 7.3, $K_j=K_{j,\setminus e}+u_eK_{j,/e}$ and $\Psi_j=u_e\Psi_{j,\setminus e}+\Psi_{j,/e}$, the deletion and the contraction being tables since e is neither a loop nor a coloop of the active table j. They are homogeneous in $u_{\mathcal{E}-e}$ of the degrees r_j, r_j-1, $n-1-r_j$ and $n-r_j$; substituting $u_e=1-x$ and $u_{\mathcal{E}-e}=xv$ gives the display, and as $x\to 0$ the terms of $x^{r_j-1}K_{j,/e}(v)$ and $x^{n-r_j-1}\Psi_{j,\setminus e}(v)$ dominate.

(iv) Let β carry the family, with $v'_{\beta(e')}=v_{e'}$ on $\mathcal{E}-e$. It maps the bases of table j onto those of table $h(j)$ with their weights, the bases through e onto those through f, so

$$K_{h(j),/f}(v')=\sum_{T\ni e}\theta_{j,T}\,{v'}^{\beta(T)-f}=\sum_{T\ni e}\theta_{j,T}\,v^{T-e}=K_{j,/e}(v),$$

and in the same way $\Psi_{h(j),\setminus f}(v')=\Psi_{j,\setminus e}(v)$, the bases avoiding e going to those avoiding f. Let β exchange the family: $T\mapsto\mathcal{E}\setminus\beta(T)$ maps the bases of table j through e onto the bases of table $h(j)$ avoiding f, with their weights, so

$$\Psi_{h(j),\setminus f}(v')=\sum_{T\ni e}\theta_{j,T}\,{v'}^{(\mathcal{E}-f)\setminus(\mathcal{E}\setminus\beta(T))}=\sum_{T\ni e}\theta_{j,T}\,{v'}^{\beta(T)-f}=K_{j,/e}(v),$$

and in the same way $K_{h(j),/f}(v')=\Psi_{j,\setminus e}(v)$. Either way the vertex product $K_{j,/e}\Psi_{j,\setminus e}$ goes to $K_{h(j),/f}\Psi_{h(j),\setminus f}$. With one table, a bijection taking e to f that carries or exchanges it exists exactly when e and f lie in one class at the centre, by Corollary 11.16 at the table's gauge, the gauge of the centre. □

Remark. Connectedness of every active table is needed for (ii). On the marks $\{0,1,2,3\}$, for the family of the list whose bases are all the two-element sets and the disconnected list with the bases $\{a,b\}$, $a\in\{0,2\}$, $b\in\{1,3\}$, at the strengths $(1,3)$, the face $S=\{0,2\}$ has $\kappa_S=1\cdot 2+3\cdot 0=2$ and $d_2(S)=1$, so $\varpi\le 2$, while $\sigma/\max_j\max(r_j-1,n-r_j-1)=4$.

Corollary 20.19 (Merged Skeleton values). *As stated, at every pair of exponents and every mass on the balance wall.*

Proof. The letters. With $\theta_{\mathcal{E}\setminus T}=\theta_T$, $\Psi(\alpha)=\sum_T\theta_T\alpha^{\mathcal{E}\setminus T}=\sum_T\theta_{\mathcal{E}\setminus T}\alpha^{\mathcal{E}\setminus T}=K(\alpha)$, the last sum running over the same bases. For a mark e the bases $T\not\ni e$ correspond to the bases $T'=\mathcal{E}\setminus T\ni e$, with $(\mathcal{E}-e)\setminus T=T'-e$ and $\theta_T=\theta_{T'}$, so

$$\Psi_{\setminus e}=\sum_{T\not\ni e}\theta_T\,\alpha^{(\mathcal{E}-e)\setminus T}=\sum_{T'\ni e}\theta_{T'}\,\alpha^{T'-e}=K_{/e}$$

(Definition 7.3), and likewise $\Psi_{/e}=K_{\setminus e}$. The Skeleton values of the scale of e are $K_{\setminus e}/(\alpha_e K_{/e})$ and $\Psi_{/e}/(\alpha_e\Psi_{\setminus e})$ (Corollary 15.4), which coincide.

The table. Bases and complements of bases are both bases, so $r=n-r$. A coloop lies in every basis, hence in no complement of one, and a loop lies in no basis, hence in every complement; both contradict the complementation, so no mark is a loop or a coloop, and the deletion $(\mathcal{B}\setminus e,\theta)$ is a table of rank r on $\mathcal{E}-e$.

The walls at $\{e\}$ and at $\mathcal{E}-e$. $d(\{e\})=d^*(\{e\})=0$, so $\kappa_{\{e\}}=m_e$. Also $d(\mathcal{E}-e)=r-r(\{e\})=r-1$ and $d^*(\mathcal{E}-e)=n-1-r(\mathcal{E}-e)=n-1-r=r-1$. On the balance wall $m_{\mathcal{E}}=sr+t(n-r)=(s+t)r$, so $\kappa_{\mathcal{E}-e}=m_{\mathcal{E}}-m_e-(s+t)(r-1)=s+t-m_e$. The proper walls being positive, $0<m_e<s+t$.

Integrating the mark. Let $g\neq e$ and $R=\mathcal{E}-e$. By Theorem 8.7 the period is the integral of $\alpha^{\mathbf{m}-\mathbf{1}}K^{-s}\Psi^{-t}=\alpha^{\mathbf{m}-\mathbf{1}}K^{-(s+t)}$ over the section $\alpha_g=1$. By Tonelli's theorem the integral over $\alpha_e=x$ may be taken first, at fixed α_R: with $K=K_{\setminus e}+xK_{/e}$, the Beta corner of a linear letter (Proposition 15.1 with one coefficient) gives

$$\int_0^\infty x^{m_e-1}\big(K_{\setminus e}+xK_{/e}\big)^{-(s+t)}dx=\Gamma\begin{bmatrix}m_e,\ s+t-m_e\\ s+t\end{bmatrix}K_{\setminus e}^{-(s+t-m_e)}K_{/e}^{-m_e},$$

convergent as $0<m_e<s+t$, and $K_{/e}=\Psi_{\setminus e}$.

The deletion. What remains is $\Gamma\begin{bmatrix}m_e,\ s+t-m_e\\ s+t\end{bmatrix}$ times the integral, over the section $\alpha_g=1$ of the orthant of R, of

$$\alpha_R^{\mathbf{m}|_R-\mathbf{1}}K_{\setminus e}^{-(s+t-m_e)}\Psi_{\setminus e}^{-m_e}\,d\alpha_{R-g},$$

the family word of the deletion at the exponents $(s+t-m_e,m_e)$. Its balance wall holds: $m_{\mathcal{E}-e}=(s+t)r-m_e$, which is $(s+t-m_e)r+m_e(n-1-r)$ as $n-1-r=r-1$. By Theorem 8.7 the section integral is $P_{\mathcal{B}\setminus e}(\mathbf{m}|_{\mathcal{E}-e};s+t-m_e,m_e)$; it is finite because P_F is, so the walls of the deletion are positive there. Since $K=\Psi$, $P_F(\mathbf{m};s,t)$ depends on the exponents only through $s+t$. At $s=t=\sigma$ and $\mathbf{m}=\sigma\mathbf{1}$, $m_e=\sigma$, which is the last identity. □

Theorem 20.20 (The scale integral of one mark). *As stated; parts (i) and (ii) are stated for every family.*

Proof. (i) By Theorem 15.3 with $B=\{e\}$ and $m_B=m_e$, at the gauge (α_e,α_R),

$$\mathrm{Sc}_{\{e\}}(\alpha;\mathbf{m};\mathbf{s},\mathbf{t})=\int_0^\infty x^{m_e-1}\prod_j K_j(x\alpha_e,\alpha_R)^{-s_j}\Psi_j(x\alpha_e,\alpha_R)^{-t_j}\,dx,$$

convergent since the walls $\kappa_{\{e\}}$ and $\kappa^{\mathrm{top}}_{\{e\}}$ are positive. At $\alpha_e = 1$, Definition 7.3 gives $K_j = K_{j,\backslash e}(\alpha_R) + xK_{j,/e}(\alpha_R)$ and $\Psi_j = x\Psi_{j,\backslash e}(\alpha_R) + \Psi_{j,/e}(\alpha_R)$ for every active table, the deletion and the contraction being tables on R as e is neither a loop nor a coloop there. At $\alpha_R = e^{2z_R}$, Theorem 7.15(i) for these tables gives $K_{j,\star}(\alpha_R) = e^{\langle \mathbf{1}, z_R\rangle}\Lambda_{j,\star}(z_R)$ and $\Psi_{j,\star}(\alpha_R) = e^{\langle \mathbf{1}, z_R\rangle}\Lambda_{j,\star}(-z_R)$ for $\star \in \{\backslash e, /e\}$. So

$$K_j = e^{\langle \mathbf{1}, z_R\rangle}\big(\Lambda_{j,\backslash e}(z_R) + x\Lambda_{j,/e}(z_R)\big),$$
$$\Psi_j = e^{\langle \mathbf{1}, z_R\rangle}\big(\Lambda_{j,/e}(-z_R) + x\Lambda_{j,\backslash e}(-z_R)\big),$$

and the powers carry the factor $e^{-\sum_j (s_j+t_j)\langle \mathbf{1}, z_R\rangle} = e^{-2\sigma\langle \mathbf{1}, z_R\rangle}$, an inactive table contributing 1. This is the display, and the rest of the integrand depends on the room only through the functions $\Lambda_{j,\backslash e}$ and $\Lambda_{j,/e}$. Corollary 16.6 at the bunch $\{e\}$, whose shape simplex is the point $u_e = 1$, gives $P_F(\mathbf{m}; \mathbf{s}, \mathbf{t}) = \int \alpha_R^{\mathbf{m}|_R - \mathbf{1}} \operatorname{Sc}_{\{e\}}((1, \alpha_R); \mathbf{m}; \mathbf{s}, \mathbf{t})\, d\alpha_{R-g}$ on the section $\alpha_g = 1$, $g \in R$. With $\alpha_R = e^{2z_R}$, $\alpha_R^{\mathbf{m}|_R - \mathbf{1}} d\alpha_{R-g} = 2^{n-2} e^{2\langle \mathbf{m}|_R, z_R\rangle} dz_{R-g}$ there, $R - g$ having $n - 2$ marks.

(ii) A realization that is an atom is a realization of a molecule (Definition 10.1), so F is connected, and Theorem 11.4 gives $\alpha^\star \propto \mathbf{1}$. By Theorem 18.1(ii), in $y = \log u$ modulo $\mathbb{R}\mathbf{1}$ the law $\mathrm{Breta}^\circ(F; \boldsymbol{\tau}; \mathbf{s}, \mathbf{t})$ has a density proportional to $e^{\langle \boldsymbol{\tau}, y\rangle - \Phi(y)}$. The target is the usage at $\alpha^\star$ (Definition 8.17),

$$\tau_e = \sum_j \big(s_j R_{j,e}(\alpha^\star) + t_j R^*_{j,e}(\alpha^\star)\big) = \partial_{y_e}\Phi(y^\star), \qquad y^\star = \log \alpha^\star,$$

with the potential Φ of Definition 8.18. With $y = y^\star + v$ the density is proportional to

$$\exp\big(\langle \nabla\Phi(y^\star), v\rangle - \Phi(y^\star + v)\big).$$

By Proposition 10.4 there are orders $\mathbf{g}_e$ of the rooms in which the potential written from e at the gauge $\alpha^\star$ (Definition 10.1),

$$(v_0, v_1, \ldots, v_{n-1}) \longmapsto \Phi_{\mathbf{X}}\Big(y^\star + v_0\mathbf{1}_e + \sum_k v_k \mathbf{1}_{g_k}\Big) \qquad (\mathbf{X} \in \{\mathbf{E}, \mathbf{O}\}),$$

is one pair of functions for every e. Hence $v \mapsto \Phi(y^\star + v)$ read in the coordinates $(v_e, v_{g_1}, \ldots, v_{g_{n-1}})$ is one function for every e, and so is its gradient at 0; the density read in these coordinates is one function for every e, and dv is invariant under the renaming. The density is invariant along $\mathbf{1}$, so it is a function of the differences $v_{g_k} - v_e$, and the law of these differences does not depend on e. As $y^\star$ is a multiple of $\mathbf{1}$, $y_{g_k} - y_e = v_{g_k} - v_e$.

(iii) The reference (proof of thm:atomforward) proves this part, a statement for one table. □

Theorem 20.23 (The junction under level form). *As stated, for every family at the centre.*

Proof. Parts (ii) and (iii) concern the Gramma $\mathsf{G}_{0;(\chi_p)_p}((v_{|p|})_p)$ alone and are proved in the reference (proof of thm:uniformjunction, parts (ii) and (iii)).

The preamble. By Proposition 20.6(iii) for every table, every half-sum has level form and the square of every difference is unchanged by the permutations of B; $q_{j,b-k}(-z_R) = q_{j,k}(z_R)$ is Proposition 20.6(i). On z_B each $(\partial_w L_{j,w})^2$ has exponents in $\{-2, 0, 2\}^B$, being a sum of products of two terms $e^{\langle z_B, \chi_p\rangle}$. A function of z_B of this kind that is unchanged by the permutations of B is a combination of the products $e^{-2\langle \mathbf{1}, z_B\rangle} e_k(e^{2z_B}) e_{k'}(e^{2z_B})$, $k \le k'$: such a product is the symmetric sum of the monomials with k exponents 2 and $b - k'$ exponents -2, plus terms with fewer of

both, and induction removes the terms (the reference, proof of thm:uniformjunction, part (i)). The coefficients are Laurent polynomials in e^{z_R}, the $\Lambda_{j,(p)}$ being such. The product over j of $(\partial_w L_{j,w})^{2l_j}$ therefore expands in products of $2|\mathbf{l}|$ of the e_k, with Laurent polynomial coefficients.

(i) At the centre $\boldsymbol{\mu} = 0$, and the first step of the proof of Theorem 20.4 gives

$$P_F(\sigma\mathbf{1};\boldsymbol{\sigma},\boldsymbol{\sigma}) = 2^{n-1}\int_{\mathbb{R}^{\mathcal{E}-g}} \prod_j \big(\Lambda_j(z)\Lambda_j(-z)\big)^{-\sigma_j}\, dz_{\mathcal{E}-g}\Big|_{z_g=0}.$$

For each table $\Lambda_j(z)\Lambda_j(-z) = L_{j,1/2}(z)^2 - \frac14(\partial_w L_{j,w}(z))^2$, and Proposition 20.1 with $a = \Lambda_j(z)$, $b = \Lambda_j(-z)$, $s = t = \sigma_j$, the midpoint $L_{j,1/2}(z)$ and $x = \partial_w L_{j,w}(z)/(2L_{j,1/2}(z)) \in (-1,1)$ gives

$$\big(\Lambda_j(z)\Lambda_j(-z)\big)^{-\sigma_j} = \sum_{l_j\ge 0} \frac{(\sigma_j)_{l_j}}{l_j!\,4^{l_j}} \big(\partial_w L_{j,w}(z)\big)^{2l_j} L_{j,1/2}(z)^{-2\sigma_j-2l_j},$$

a series of nonnegative terms. Open each power of the half-sum,

$$L_{j,1/2}^{-2\sigma_j-2l_j} = \Gamma(2\sigma_j+2l_j)^{-1}\int_0^\infty y_j^{2\sigma_j+2l_j-1} e^{-y_j L_{j,1/2}}\, dy_j;$$

by Tonelli's theorem the sums and integrals may be taken in the order of the statement. With $\upsilon_k = \sum_j y_j q_{j,k}(z_R)$,

$$\sum_j y_j L_{j,1/2}(z) = \sum_k \upsilon_k\, e^{-\langle \mathbf{1}, z_B\rangle} e_k\big(e^{2z_B}\big),$$

and inserting $e^{-\langle \mathbf{1}, z_B\rangle} e_k(e^{2z_B})$ under the exponential of minus this sum is $-\partial_{\upsilon_k}$. With the expansion of the preamble and Definition 2.1 (index 0, the integral over z_B),

$$\int_{\mathbb{R}^B} \prod_j \big(\partial_w L_{j,w}(z)\big)^{2l_j} e^{-\sum_j y_j L_{j,1/2}(z)}\, dz_B$$
$$= \sum_{|\mathbf{h}|=2|\mathbf{l}|} c_{\mathbf{h}}^{(\mathbf{l})}(z_R)\Big((-\partial_{\boldsymbol{\upsilon}})^{\mathbf{h}}\, \mathsf{G}_{0;(\chi_p)_p}\big((\upsilon_{|p|})_p\big)\Big)\Big|_{\boldsymbol{\upsilon}=\sum_j y_j \mathbf{q}_j(z_R)}.$$

Each term converges. The family being a molecule, some active table j has $c_j(B) \ge 1$ (Definition 8.1), so its patterns at B fill at least two consecutive levels $k, k+1$ (Theorem 12.7), and $q_{j,k}, q_{j,k+1} > 0$, each being a sum of nonnegative terms one of which is positive; by $q_{j,b-k}(-z_R) = q_{j,k}(z_R)$ also $q_{j,b-k}, q_{j,b-k-1} > 0$. The vectors χ_p of these four levels are closed under negation, $\chi_{B\setminus p} = -\chi_p$, and span $\mathbb{R}^B$, since $\chi_{p\cup\{e\}} - \chi_p = 2\mathbf{e}_e$ for $|p| = k$, $e \notin p$; so they positively span $\mathbb{R}^B$, the exponential of $-\sum_j y_j L_{j,1/2}(z)$ decays in z_B faster than every exponential, and the inserted exponentials are integrable against it.

(iv) For each table the swap τ of e and f keeps B, fixes R and exchanges table j, the bijection of the tables being the identity. Proposition 20.5 gives $c_{j,\tau(p)}(1-w;z_R) = c_{j,p}(w;z_R)$. At $w = \frac12$, $c_{j,\{f\}}(\frac12;\cdot) = c_{j,\{e\}}(\frac12;\cdot)$; in the derivative, $\partial_w c_{j,\varnothing} = \partial_w c_{j,B} = 0$ and $\partial_w c_{j,\{f\}} = -\partial_w c_{j,\{e\}}$. With $c_{j,B}(\frac12;z_R) = c_{j,\varnothing}(\frac12;-z_R)$ (Proposition 20.6(i)) this gives the two displayed forms. Evenness: $c_{j,\{e\}}(\frac12;-z_R) = c_{j,\{f\}}(\frac12;z_R) = c_{j,\{e\}}(\frac12;z_R)$ and $\partial_w c_{j,\{e\}}(w;-z_R) = -\partial_w c_{j,\{f\}}(w;z_R) = \partial_w c_{j,\{e\}}(w;z_R)$, by Proposition 20.6(i). In (i) change (z_e, z_f) to (z_+, z_-), with $dz_e\, dz_f = \frac12 dz_+ dz_-$. Then $\prod_j(\partial_w L_{j,w})^{2l_j} = (e^{z_-} - e^{-z_-})^{2|\mathbf{l}|}\prod_j(\partial_w c_{j,\{e\}})^{2l_j}$ and

$$\sum_j y_j L_{j,1/2}(z) = e^{-z_+}C_\varnothing(z_R) + e^{z_+}C_\varnothing(-z_R) + \big(e^{z_-} + e^{-z_-}\big)C_e(z_R).$$

The integral over z_+ is $\mathsf{G}_{0;(1,-1)}\big(C_\varnothing(-z_R), C_\varnothing(z_R)\big)$ (Definition 2.1 on one scale e^{z_+}), and the integral over z_- is Lemma 20.22 with $\xi = C_e(z_R)$ and the power $|\mathbf{l}|$, $4^{|\mathbf{l}|}(\frac{1}{2})_{|\mathbf{l}|} C_e^{-|\mathbf{l}|}\mathsf{G}_{|\mathbf{l}|;(1,-1)}(C_e, C_e)$. The constants collect to $2^{n-1}\cdot\frac{1}{2}\cdot 4^{|\mathbf{l}|}\prod_j 4^{-l_j} = 2^{n-2}$, which is the display; every term is nonnegative. □

Remark. With one table, $(\frac{1}{2})_l(\sigma)_l/(l!\,\Gamma(2\sigma+2l)) = \frac{1}{l!}\Gamma\,{}_2^{}{}_3\!\left[\begin{matrix}\sigma+l,\ \frac{1}{2}+l\\ 2\sigma+2l,\ \sigma,\ \frac{1}{2}\end{matrix}\right]$ and $y^{2\sigma+2l-1}(yc_{\{e\}})^{-l} = y^{2\sigma+l-1}c_{\{e\}}^{-l}$, which is the reference's form of (iv).

Theorem 20.40 (A series connection closes at its reach). *As stated, for series connections and for series connections of the dual table.*

Proof. (i) By Proposition 20.37(i), $f_B = C^{-s}C'^{-t}\prod_i f_i^\circ$, and by Proposition 20.37(ii), which is Lemma 20.30 applied $q-1$ times, f_B has a lattice expansion of reach $(\sum_i\sqrt{x_i})^2$ whose terms are the products of the terms of the parts collected by exponent. A function has at most one lattice expansion (Definition 20.28), so these are the coefficients $\beta_{\eta,j}$ of Theorem 20.34, and $\operatorname{reach}(B) \le (\sum_i\sqrt{x_i})^2 < \inf\varrho_R$, the reach being an infimum. Theorem 20.34(ii) applies: the even share closes toward the level d on the lattice of continued periods of the bunch family, with the bound for every $x > \operatorname{reach}(B)$, in particular for every $x > (\sum_i\sqrt{x_i})^2$. Under the hypotheses of Proposition 20.37(iii), $\operatorname{reach}(B) = (\sum_i\sqrt{\sup\varrho_i})^2$, and Theorem 20.39(ii) gives the root rate $\operatorname{reach}(B)/\inf\varrho_R$. For a series bunch the parts are the marks (Proposition 20.37), with

$$\begin{aligned} f_e^\circ(y) &= \int_0^\infty x^{m_e-s-1}e^{-w_e/x-yw_ex}\,dx = \mathsf{G}_{m_e-s;(1,-1)}(yw_e, w_e)\\ &= (yw_e)^{s-m_e}\mathsf{G}_{m_e-s;(1,-1)}\big(1, w_e^2y\big)\end{aligned}$$

by the torus homogeneity of the Gramma; by Lemma 20.29(iii) it has a lattice expansion of reach w_e^2, a power of y keeping the reach (Lemma 20.30). Proposition 20.36(iii) gives $\operatorname{reach}(B) = \inf\varrho_B = (\sum_e w_e)^2$ exactly, and Proposition 20.36(i) gives the coefficients.

(ii) The reference (proof of thm:classcloses, part (ii)) gives the argument for a parallel bunch, and it applies to a connection. The dual table at the exponents (t,s) has the same period (Proposition 8.15). Since $K^* = \Psi$ and $\Psi^* = K$ (Proposition 7.2), the dual node has the bunch B, of width one in the dual table, the room R, the ratios $1/\varrho_B$ and $1/\varrho_R$, and its levels swapped: its level d carries the even letter of the level r of the given node. No slope on the room being negative, $\sup\varrho_R < \infty$ (Lemma 19.15), so $\inf(1/\varrho_R) > 0$ and no slope on the room of the dual node is positive (the same lemma for the dual node). Part (i) for the dual node, whose bunch is a series connection with the reaches x_i^*, closes the even share toward its level d, the level r of the given node, when $(\sum_i\sqrt{x_i^*})^2 < 1/\sup\varrho_R$, at a root rate at most $(\sum_i\sqrt{x_i^*})^2\sup\varrho_R$. For a parallel bunch, the dual pattern weights are $\theta'^*_B = \theta'_\varnothing$ and $\theta'^*_{B-e} = \theta'_{\{e\}}$, so the w_e of the dual series bunch are $\theta'_{\{e\}}/\theta'_\varnothing$, $x_e^* = w_e^2$, and the root rate is exact by (i). The ratio of the bunch of the dual node is $1/\varrho_B = (\sum_e w_e/u_e)(\sum_e w_eu_e)$, whose least value $(\sum_e w_e)^2$ is taken at the point of equal coordinates of Δ_B (Proposition 20.36(ii)); so $\sup\varrho_B = (\sum_e w_e)^{-2}$, the condition reads $\sup\varrho_R < \sup\varrho_B$, and the root rate is $(\sum_e w_e)^2\sup\varrho_R = \sup\varrho_R/\sup\varrho_B$. □

Theorem 20.59 (One tree suffices). *As stated; the chain clause of (iii) is stated whenever some active list is connected.*

Proof. All of the theorem but the chain clause of (iii) is the reference's (proof of thm:onetree). For the chain clause, let some active list of the molecule F be connected. The weights of lists factor

across every split, so Corollary 20.9 applies: every peel leaves one childcule, the Foreman tree is a chain (Corollary 20.8), and at every realization, the centre and every lean, $|B_0| \le |B_1| \le \cdots \le |B_{d-1}| \le |L|$, L the leaf. The shape of the bunch B_k then has $|B_k| - 1 \le |L| - 1$ integrations, and its node adds one, the total of the bunch against its room, by (ii). A molecule of one list is such an F, its list being connected. □

50.21 Chapter 21: gluing and what crosses it

Theorem 21.5 (Replacement of marks by blocks). *As stated: every mark is replaced, by a block of any size and by either rule.*

Proof. One mark, first rule. Let h be replaced by a block X of q marks by the first rule, the other marks left in place: the new sets are the bases $T \not\ni h$ and the sets $(T - h) \sqcup \{x\}$, $T \ni h$, $x \in X$, each with the weight θ_T. If h is neither a loop nor a coloop, $(\mathcal{B}, \theta)$ is a cell on $(\mathcal{E} - h) \sqcup \{h\}$ with the hinge h, and the parallel block $\binom{X \sqcup \{g\}}{1}$ is a cell on $X \sqcup \{g\}$ whose deletion of g has the singletons of X as bases and whose contraction of g has the single basis $\varnothing$. By 21.2 for these two cells, the sets $\{x\} \sqcup (T - h)$, $T \ni h$, and $\varnothing \sqcup T$, $T \not\ni h$, are the bases of a table of rank $1 + r - 1 = r$: they are the new sets. If h is a loop, no basis contains h, and the new sets are the bases of $\mathcal{B}$ read on $\mathcal{E} - h$, the marks of X being loops: a table of rank r. If h is a coloop, every basis contains h, and the new sets are the sets $(T - h) \sqcup \{x\}$: the direct sum of the contraction of h and the table $\binom{X}{1}$, a table of rank r, the exchange property of a direct sum holding in each summand.

One mark, complementary rule. The dual table has the bases $\mathcal{E} \setminus T$ (7.2). The first rule at h on the dual table gives the sets $\mathcal{E} \setminus T$ for $T \ni h$ and $(\mathcal{E} \setminus T) - h + x$ for $T \not\ni h$, $x \in X$, the bases of a table on $(\mathcal{E} - h) \sqcup X$ by the first case. Their complements in $(\mathcal{E} - h) \sqcup X$ are $(T - h) \sqcup X$ for $T \ni h$ and $T \sqcup (X - x)$ for $T \not\ni h$, the sets of the complementary rule, and the complements of the bases of a table are the bases of its dual. Its rank is $(|\mathcal{E}| - 1 + q) - (|\mathcal{E}| - r) = r + q - 1$.

All marks. The rule at a mark h decides the part of a new set in X_h from whether $h \in T$ alone, so replacing the marks one at a time, in any order, gives the sets of the statement; by the two cases each step gives a table, and the step at $h \in \mathcal{E}_2$ raises the rank by $q_h - 1$. A new set T' determines $T = \{h \in \mathcal{E}_1 : X_h \cap T' \ne \varnothing\} \sqcup \{h \in \mathcal{E}_2 : X_h \subseteq T'\}$ and the choice made in every block, so it carries the one weight θ_T. A block of one mark gives back its mark under either rule.

Substitution. When no mark is a loop or a coloop, $(\mathcal{B}, \theta)$ is a core (21.1), and the parallel block $\binom{X_h \sqcup \{g_h\}}{1}$ and the series block $\binom{X_h \sqcup \{g_h\}}{q_h}$ are cells, g_h being neither a loop nor a coloop of either. In the parallel block the deletion of g_h has the singletons of X_h as bases and the contraction the single basis $\varnothing$; in the series block the deletion has the single basis X_h and the contraction the sets $X_h - x$. So the sets of the substitution contain, for a basis T of the core, one mark of X_h for $h \in T \cap \mathcal{E}_1$, none for $h \in \mathcal{E}_1 \setminus T$, all of X_h for $h \in T \cap \mathcal{E}_2$ and all but one for $h \in \mathcal{E}_2 \setminus T$, each with the weight θ_T, every weight of a block being 1: the table of the statement.

Letters. By the correspondence between the new sets and the pairs of a basis T and a choice in every block, $K'(\alpha)$ is the sum over T of θ_T times the product over the blocks of the sum, over the choices, of the monomials of the chosen marks: $e_1(\alpha_{X_h})$ for $h \in T \cap \mathcal{E}_1$, 1 for $h \in \mathcal{E}_1 \setminus T$, $e_{q_h}(\alpha_{X_h})$ for $h \in T \cap \mathcal{E}_2$ and $e_{q_h - 1}(\alpha_{X_h})$ for $h \in \mathcal{E}_2 \setminus T$. Taking out $\prod_{h \in \mathcal{E}_2} e_{q_h - 1}$,

$$K' = \prod_{h \in \mathcal{E}_2} e_{q_h - 1} \sum_T \theta_T \prod_{h \in T \cap \mathcal{E}_1} e_1 \prod_{h \in T \cap \mathcal{E}_2} \frac{e_{q_h}}{e_{q_h - 1}},$$

the first display. The complement of a new set meets X_h in all of X_h but the chosen mark for $h \in T \cap \mathcal{E}_1$, in all of X_h for $h \in \mathcal{E}_1 \setminus T$, in nothing for $h \in T \cap \mathcal{E}_2$ and in the missing mark for

$h \in \mathcal{E}_2 \setminus T$, so

$$\Psi' = \sum_T \theta_T \prod_{h \in T \cap \mathcal{E}_1} e_{q_h - 1} \prod_{h \in \mathcal{E}_1 \setminus T} e_{q_h} \prod_{h \in \mathcal{E}_2 \setminus T} e_1 = \prod_{h \in \mathcal{E}_1} e_{q_h - 1} \sum_T \theta_T \prod_{h \in \mathcal{E}_1 \setminus T} \frac{e_{q_h}}{e_{q_h - 1}} \prod_{h \in \mathcal{E}_2 \setminus T} e_1,$$

which is $\prod_{h \in \mathcal{E}_1} e_{q_h - 1}\, \Psi(\beta^*)$ with $\beta^*_h = e_{q_h}/e_{q_h - 1}$ on $\mathcal{E}_1$ and $\beta^*_h = e_1$ on $\mathcal{E}_2$, since $\Psi(\beta^*) = \sum_T \theta_T (\beta^*)^{\mathcal{E} \setminus T}$. For one block at h, every other block of one mark, K and Ψ are affine in α_h, $K = K_{\setminus h} + \alpha_h K_{/h}$ and $\Psi = \alpha_h \Psi_{\setminus h} + \Psi_{/h}$ (7.3), and the two displays become the four formulas of the statement. In scale and shape, e_k is homogeneous of degree k, $e_1(u) = |u| = 1$ on Δ_X, and the measure is 2.7. □

Theorem 21.6 (Counts, walls and atoms under replacement). *As stated: (i) and (ii) for blocks of any sizes and either rule at each mark; (iii) at every positive exponent pairs.*

Proof. (i) The marks and the rank are 21.5. At $\alpha = \mathbf{1}$, $e_1 = q_h$, $e_{q_h} = 1$ and $e_{q_h - 1} = q_h$ on a block of q_h marks, so the first display of 21.5 gives the total weight $K'(\mathbf{1}) = \prod_{h \in \mathcal{E}_2} q_h \cdot K\big((q_h)_{h \in \mathcal{E}_1}, (q_h^{-1})_{h \in \mathcal{E}_2}\big)$, and expanding K over the bases gives the sum displayed; it counts q_h choices at $h \in T \cap \mathcal{E}_1$ and q_h at $h \in \mathcal{E}_2 \setminus T$. With $\mathcal{E}_2 = \varnothing$ it is $K((q_h)_h)$; with $\mathcal{E}_1 = \varnothing$ it is $\prod_h q_h\, K((q_h^{-1})_h) = \Psi((q_h)_h)$ (7.2).

(ii) By 7.13, $d'(Y) = \min_{T'} |T' \cap Y|$ and $d^{*\prime}(Y) = \min_{T'} |Y \setminus T'|$ over the new bases T', which are the pairs of a basis T and a choice in every block (proof of 21.5). Fix T and minimize over the choices, block by block. In $|T' \cap Y|$ a block contributes, at its least: for $h \in T \cap \mathcal{E}_1$, 1 if $X_h \subseteq Y$ and 0 otherwise, the chosen mark avoiding Y when it can; for $h \in \mathcal{E}_1 \setminus T$, 0; for $h \in T \cap \mathcal{E}_2$, $|X_h \cap Y|$; for $h \in \mathcal{E}_2 \setminus T$, $\max(|X_h \cap Y| - 1, 0)$, the missing mark taken in Y when it can. Writing $|X_h \cap Y| = \max(|X_h \cap Y| - 1, 0) + [h \in \lceil Y \rceil]$ for $h \in \mathcal{E}_2$, the least value at T is

$$\sum_{h \in \mathcal{E}_2} \max\big(|X_h \cap Y| - 1, 0\big) + \big|T \cap \big((\lfloor Y \rfloor \cap \mathcal{E}_1) \sqcup (\lceil Y \rceil \cap \mathcal{E}_2)\big)\big|,$$

and the least over T is $d'(Y)$ as stated (7.13). In $|Y \setminus T'|$ a block contributes, at its least: for $h \in T \cap \mathcal{E}_1$, $\max(|X_h \cap Y| - 1, 0)$; for $h \in \mathcal{E}_1 \setminus T$, $|X_h \cap Y|$; for $h \in T \cap \mathcal{E}_2$, 0; for $h \in \mathcal{E}_2 \setminus T$, 1 if $X_h \subseteq Y$ and 0 otherwise. In the same way $d^{*\prime}(Y)$ is as stated, and $c'(Y) = |Y| - d'(Y) - d^{*\prime}(Y)$ is 7.12. Under the first rule alone, $r'(Y) = \max_{T'} |T' \cap Y| = \max_T |T \cap \lceil Y \rceil| = r(\lceil Y \rceil)$, $d'(Y) = d(\lfloor Y \rfloor) = r - r(\mathcal{E} \setminus \lfloor Y \rfloor)$ (7.12) and $c'(Y) = r'(Y) - d'(Y)$ (7.13). Under the complementary rule alone, $|Y| = \sum_h \max(|X_h \cap Y| - 1, 0) + |\lceil Y \rceil|$, so

$$c'(Y) = |\lceil Y \rceil| - d(\lceil Y \rceil) - d^*(\lfloor Y \rfloor) = |\lceil Y \rceil| - |\lfloor Y \rfloor| + r(\mathcal{E} \setminus \lceil Y \rceil) + r(\lfloor Y \rfloor) - r.$$

If $Y = \bigcup_{h \in S} X_h$, then $\lceil Y \rceil = \lfloor Y \rfloor = S$, $d'(Y) = \sum_{h \in S \cap \mathcal{E}_2} (q_h - 1) + d(S)$, $d^{*\prime}(Y) = \sum_{h \in S \cap \mathcal{E}_1} (q_h - 1) + d^*(S)$ and $|Y| = \sum_{h \in S} q_h$, so $c'(Y) = |S| - d(S) - d^*(S) = c(S)$. If $\varnothing \neq Y \subsetneq X_h$, then $\lceil Y \rceil = \{h\}$ and $\lfloor Y \rfloor = \varnothing$: for $h \in \mathcal{E}_1$, $d'(Y) = 0$ and $d^{*\prime}(Y) = |Y| - 1 + d^*(\{h\})$, and for $h \in \mathcal{E}_2$, $d'(Y) = |Y| - 1 + d(\{h\})$ and $d^{*\prime}(Y) = 0$; a seed table connected on at least two marks has $c(\{h\}) = 1 - d(\{h\}) - d^*(\{h\}) > 0$, so $d(\{h\}) = d^*(\{h\}) = 0$ and $c'(Y) = 1$.

(iii) Write $X_e = \{e\} \times \{1, \dots, q\}$. For $h \in H$, carrying table j to table $\tau(j)$ (11.13), put $\hat{h}(e, i) = (h(e), i)$; the rule and q are the same at every mark, so $\hat{h}$ maps the replaced table j onto the replaced table $\tau(j)$ with the same weights, and the two tables have the same pairs: $\hat{h}$ carries the replaced family to itself. A permutation of X_e fixing the other new marks maps every replaced table onto itself with its weights, the sets of the rule being symmetric in the marks of X_e. The group generated by these bijections is transitive on the new marks, H being transitive on $\mathcal{E}$.

The replaced family is connected. The seed family is one molecule: a molecule $M \neq \mathcal{E}$ would be a union of molecules of every table (7.9), with $|T \cap M|$ constant on the bases of every table and so $c_j(M) = 0$ for every j (7.13), all tables being active at positive pairs. Let $e \neq f$ be linked in table j: by 7.7 some basis T of table j has $e \in T$, $f \notin T$ and $T - e + f$ a basis. Under the first rule, a new basis T' from T choosing x in X_e gives $T' - x + x'$, the new basis from T choosing x', and $T' - x + y$, $y \in X_f$, the new basis from $T - e + f$ choosing y with the same choices elsewhere; under the complementary rule, the new basis T' from $T - e + f$ missing x' in X_e gives $T' - x + x'$, the one missing x, and the new basis T'' from T missing y in X_f gives $T'' - x + y$, the new basis from $T - e + f$ missing x. By 7.7 any two marks of X_e are linked, and every mark of X_e is linked to every mark of X_f. Every mark is linked to another mark, the seed family being one molecule on at least two marks, so the new marks form one molecule. Then no nonempty proper set Y of new marks has $c'_j(Y) = 0$ in every table: by 7.13 $|T' \cap Y|$ would be constant on the bases of every table, and by 7.8 no circuit would join Y to its complement.

Finally $((s_j, t_j)_j; \mathbf{1})$ is a realization of the replaced family, and every bijection above fixes the table's gauge, $\hat{h}^* \log \mathbf{1} = \log \mathbf{1}$. By 11.14 the reading of the image of a mark equals the reading of the mark, so the reading is constant on the new marks, which form one molecule: the realization is an atom (10.1). □

Remark. In exact rational arithmetic (receipt `check_blocks_splice.py`): on the seed of rank two on $\{a, b, c, d\}$ whose bases are the pairs other than $\{c, d\}$, with weights $1, 2, \frac{3}{2}, 5, \frac{1}{3}$, blocks of $2, 3, 1, 2$ marks, the first rule at a, c and the complementary rule at b, d, the new sets satisfy the exchange property, the rank is $r + \sum_{h \in \mathcal{E}_2}(q_h - 1)$, the total weight is that of (i), $d'(Y)$ and $d^{*\prime}(Y)$ are those of (ii) at every one of the 2^8 sets Y, and unions of full blocks keep the width; with the first rule at every mark and the same sizes, $r'(Y) = r(\lceil Y \rceil)$, $d'(Y) = r - r(\mathcal{E} \setminus \lfloor Y \rfloor)$ and the total weight is $K((q_h)_h)$.

Proposition 21.8 (Dual pairs). *As stated.*

Proof. Write θ for the one system of weights of $\mathcal{A}$. (i) The bases of $\mathcal{A}$ are the $X \in \mathcal{A} \setminus g$ and the $Y + g$ with $Y \in \mathcal{A}/g$ (7.3). If $\mathcal{A}$ is a dual pair, the complement $(B \setminus X) + g$ of X is a basis with the weight θ_X, and the complement $B \setminus Y$ of $Y + g$ is a basis of $\mathcal{A} \setminus g$ with the weight θ_{Y+g}: the bases are closed under complement with equal weights. Conversely, if they are, $X \in \mathcal{A} \setminus g$ gives the basis $(B \setminus X) + g$ with the weight θ_X, so $B \setminus X \in \mathcal{A}/g$, and $Y \in \mathcal{A}/g$ gives $B \setminus Y \in \mathcal{A} \setminus g$: $\mathcal{A}/g$ is the dual of $\mathcal{A} \setminus g$ with its weights. Since g is neither a loop nor a coloop, $\mathcal{A} \setminus g$ has the rank $r_{\mathcal{A}}$ and $\mathcal{A}/g$ the rank $r_{\mathcal{A}} - 1$, while the dual of $\mathcal{A} \setminus g$ has the rank $|B| - r_{\mathcal{A}}$; so $|B| = 2r_{\mathcal{A}} - 1$.

(ii) $K_{\mathcal{A}/g} = \sum_Y \theta_{Y+g} \alpha^Y = \sum_X \theta_X \alpha^{B \setminus X} = \psi$ and $\Psi_{\mathcal{A}/g} = \sum_Y \theta_{Y+g} \alpha^{B \setminus Y} = \sum_X \theta_X \alpha^X = k$. So $\gamma^K_{\mathcal{A}} = K_{\mathcal{A} \setminus g}/K_{\mathcal{A}/g} = k/\psi$ and $\gamma^{\Psi}_{\mathcal{A}} = \Psi_{\mathcal{A}/g}/\Psi_{\mathcal{A} \setminus g} = k/\psi$ (21.1).

(iii) The cell $\binom{\{h,g\}}{1}$ has the deletion with the basis $\{h\}$ and the contraction with the basis $\varnothing$, the dual of $\{h\}$ on $\{h\}$, so it is a dual pair with $k = \alpha_h$ and $\psi = 1$. By 21.4 and (ii), $K = \prod_i K_{\mathcal{A}_i/g_i} K_{\mathcal{H}}\big((k_i/\psi_i)_i\big) = \pi K_{\mathcal{H}}\big((k_i/\psi_i)_i\big)$ and $\Psi = \prod_i \Psi_{\mathcal{A}_i \setminus g_i} \Psi_{\mathcal{H}}\big((k_i/\psi_i)_i\big) = \pi \Psi_{\mathcal{H}}\big((k_i/\psi_i)_i\big)$. $K_{\mathcal{H}}$ and $\Psi_{\mathcal{H}}$ are homogeneous of the degrees $r_{\mathcal{H}}$ and $q - r_{\mathcal{H}}$, so multiplying the arguments by π gives the two identities; both sides are polynomials, $r_{\mathcal{H}} \geq 1$ and $q - r_{\mathcal{H}} \geq 1$ since no mark of the core is a loop or a coloop. □

Corollary 21.11 (The width of the marks left in place). *As stated.*

Proof. In 21.10 take $S \subseteq L$: the part of S in the cell $\binom{\{l,g\}}{1}$ of a mark $l \in S$ is $\{l\}$, with $d(\{l\}) = d^*(\{l\}) = 0$ and $d(\{l, g\}) = d^*(\{l, g\}) = 1$, the bases being $\{l\}$ and $\{g\}$ (7.13); every other cell meets S in $\varnothing$, and its hinge, neither a loop nor a coloop, has $d(\{g\}) = d^*(\{g\}) = 0$. So

$D(S) = D^*(S) = S$, read on the marks of the core, and $d(S) = d_{\mathcal{H}}(S)$, $d^*(S) = d^*_{\mathcal{H}}(S)$, whence $c(S) = |S| - d(S) - d^*(S) = c_{\mathcal{H}}(S)$ (7.12). By 7.12, $d_{\mathcal{H}}(S) = r_{\mathcal{H}} - r_{\mathcal{H}}(L \sqcup H' \setminus S)$, so

$$c_{\mathcal{H}}(S) = r_{\mathcal{H}}(S) + r_{\mathcal{H}}(L \sqcup H' \setminus S) - r_{\mathcal{H}} \le r_{\mathcal{H}}(L \sqcup H' \setminus S) \le |L \setminus S| + |H'|,$$

the rank of a set being at most its size and $r_{\mathcal{H}}(S) \le r_{\mathcal{H}}$. In $\binom{B \sqcup \{h_1,\dots,h_c\}}{c}$ the bases are the sets of c marks, which meet B in every number from 0 to c, so B has the width c (7.13); no h_i is a loop or a coloop, and by the first part the width stays c after any cells are substituted at the h_i. □

Lemma 21.12 (Two-sums of cells; hinge walls). *As stated, for cell families glued table by table.*

Proof. That $\mathcal{A} \oplus_g \mathcal{A}'$ is a table of rank $r_{\mathcal{A}} + r_{\mathcal{A}'} - 1$, plain when the cells are, in which B is a bunch of width one with the cells $\mathcal{A}$ and $\mathcal{A}'$, and that a table with a bunch of width one and factoring weights is the two-sum of its two cells, is the reference, proof of lem:twosumpieces(i), the weights multiplied letter by letter. The two-sum is $\binom{\{h_1,h_2\}}{1}\langle \mathcal{A}, \mathcal{A}' \rangle$: the bases $\{h_1\}$ and $\{h_2\}$ of the core give the two kinds of sets of 21.2 (21.1). So F is substituted table by table, with the core $\binom{\{h_1,h_2\}}{1}$ in every table and the cells $\mathcal{A}_j$ at h_1 and $\mathcal{A}'_j$ at h_2, and 21.10 at $S = B$ gives the wall $m_B - \sum_j \big(s_j(r_{\mathcal{A}_j} - 1) + t_j(|B| - r_{\mathcal{A}_j})\big) = \kappa_{F_B}$, and at $S = R$ the wall κ_{F_R}. Table j of F has the rank $r_j = r_{\mathcal{A}_j} + r_{\mathcal{A}'_j} - 1$ on $n = |B| + |R|$ marks, so

$$\kappa_{F_B} + \kappa_{F_R} = m_{\mathcal{E}} - \sum_j \big(s_j(r_j - 1) + t_j(n - r_j - 1)\big) = \kappa_{\mathcal{E}} + \sum_j (s_j + t_j) = \kappa_{\mathcal{E}} + 2\sigma.$$

With the mass $2\sigma - \kappa_{F_B}$ on g, the imbalance of F_B on $B \sqcup \{g\}$ is

$$m_B + 2\sigma - \kappa_{F_B} - \sum_j \big(s_j r_{\mathcal{A}_j} + t_j(|B| + 1 - r_{\mathcal{A}_j})\big) = 2\sigma - \sum_j (s_j + t_j) = 0,$$

on the balance wall of F or off it. □

Theorem 21.14 (Splicing hinges in pairs). *As stated; (iii) holds for any number of cells and any graph of pairs.*

Proof. (i) and (ii) are the reference, proof of thm:hingepairs(i),(ii). (iii) In the direct sum of the cells the letters are $K = \prod_i K_{\mathcal{A}_i}$ and $\Psi = \prod_i \Psi_{\mathcal{A}_i}$ (7.9), and by 21.13, with $G = \bigsqcup_i G_i$,

$$K = \sum_{(p_i)_i} \alpha_G^{\sqcup_i p_i} \prod_i K_{\mathcal{A}_i,(p_i)}, \qquad \Psi = \sum_{(p_i)_i} \alpha_G^{G \setminus \sqcup_i p_i} \prod_i \Psi_{\mathcal{A}_i,(p_i)},$$

over $p_i \subseteq G_i$, absent channels counting as zero. Splicing a pair $\{a, b\}$ acts on a monomial α_G^P by $(\partial_{\alpha_a} + \partial_{\alpha_b})\alpha_G^P|_{\alpha_a = \alpha_b = 0}$, which is α_G^{P-a} when $a \in P \not\ni b$, α_G^{P-b} when $b \in P \not\ni a$, and 0 otherwise; on $\alpha_G^{G \setminus P}$ it is likewise nonzero exactly when P contains one of a, b. The splicings of disjoint pairs commute and act on different variables, so splicing all pairs keeps the terms in which $P = \sqcup_i p_i$ is $p \sqcup J$ with $p \subseteq G'$ and J containing exactly one hinge of every pair, and leaves $\alpha_{G'}^p$ in K and $\alpha_{G'}^{G' \setminus p}$ in Ψ. By (ii) the result is the letters of the spliced cell $\mathcal{A}$, and by the Taylor cube (12.7) its channels are the coefficients of these monomials:

$$K_{\mathcal{A},(p)} = \sum_J \prod_i K_{\mathcal{A}_i,((p \sqcup J) \cap G_i)}, \qquad \Psi_{\mathcal{A},(p)} = \sum_J \prod_i \Psi_{\mathcal{A}_i,((p \sqcup J) \cap G_i)}.$$

The marks other than hinges are $\bigsqcup_i B_i$, and the rank is $\sum_i r_{\mathcal{A}_i} - k$ by (ii). The degrees add up: $\sum_i \big(r_{\mathcal{A}_i} - |(p \sqcup J) \cap G_i|\big) = \sum_i r_{\mathcal{A}_i} - k - |p|$, since $|J| = k$, and $\sum_i \big(n_{\mathcal{A}_i} - r_{\mathcal{A}_i} + |(p \sqcup J) \cap G_i|\big) = n_{\mathcal{A}} - r_{\mathcal{A}} + |p|$, since $n_{\mathcal{A}} - r_{\mathcal{A}} = \sum_i (n_{\mathcal{A}_i} - r_{\mathcal{A}_i}) + k$. Each channel of $\mathcal{A}$ is a sum of products of one channel of each cell, so the map is multilinear. For two cells with the pairs named by I, a set J is given by the set $I' \subseteq I$ of the pairs whose hinge on the side of $\mathcal{A}_1$ it contains, $(p \sqcup J) \cap G_1 = p_1 \sqcup I'$ and $(p \sqcup J) \cap G_2 = p_2 \sqcup (I \setminus I')$: the bilinear map displayed. With $k = 1$ and no other hinges, $K_{\mathcal{A},(\varnothing)} = K_{\mathcal{A}_1 \setminus g_1} K_{\mathcal{A}_2/g_2} + K_{\mathcal{A}_1/g_1} K_{\mathcal{A}_2 \setminus g_2}$ and $\Psi_{\mathcal{A},(\varnothing)} = \Psi_{\mathcal{A}_1 \setminus g_1} \Psi_{\mathcal{A}_2/g_2} + \Psi_{\mathcal{A}_1/g_1} \Psi_{\mathcal{A}_2 \setminus g_2}$, the letters of 21.7(iii). □

Remark. In exact arithmetic (receipt `check_blocks_splice.py`): three cells in a closed path, a weighted $\binom{\{x_1,x_2\} \sqcup G_1}{3}$ with three hinges, one of them unpaired, a weighted $\binom{\{y_1,y_2\} \sqcup G_2}{2}$ and a weighted $\binom{\{z_1\} \sqcup G_3}{1}$ with two hinges each, spliced along three pairs, one between each two cells: both channels of the spliced cell at both values of the unpaired hinge are the sums over J of the products of the channels of the three cells.

Theorem 21.17 (Multivectors bound what crosses). *As stated; (iii) holds at any tensor rank.*

Proof. (i) and (ii) are the reference, proof of thm:cutrank(i),(ii), with the interface rank for the cut rank; (ii) is proved there at any tensor rank, the interface rank being subadditive. (iii) By (i) and (ii), $\operatorname{rank} \Theta_B^{(k)} \le \operatorname{ir}_k(\boldsymbol{\omega})^2 \le i_k^2$ with $i_k = \sum_l \binom{c_l}{k - d_l}$, and summing over the levels bounds the interface dimension $\sum_k \operatorname{rank} \Theta_B^{(k)}$ (21.15); for a real multivector (i) gives $\operatorname{rank} \Theta_B^{(k)} \le \frac{1}{2} \operatorname{ir}_k(\boldsymbol{\omega})(\operatorname{ir}_k(\boldsymbol{\omega}) + 1)$, and $x \mapsto \frac{1}{2} x(x+1)$ increases on $[0, \infty)$. The bounds involve only the widths and the floors of the slices. A determinantal table has a multivector of tensor rank one, $\boldsymbol{\omega}_T = \det A_T$ (7.20); a set T is a basis exactly when $\det A_T \neq 0$, so the column space of A_S has the dimension $r(S)$, the column spaces of A_B and A_R span $\mathbb{F}^r$ and meet in dimension $r(B) + r(R) - r = c(B)$, and $d_1 = r - r(R) = d(B)$ (7.12). So $\operatorname{ir}_k(\boldsymbol{\omega}) \le \binom{c(B)}{k - d(B)}$, and $\sum_k \binom{c(B)}{k - d(B)}^2 = \sum_i \binom{c(B)}{i}^2 = \binom{2c(B)}{c(B)}$. At width one $\binom{1}{k - d(B)} = 1$ at $k = d(B)$ and $k = d(B) + 1$: one bunch letter at each level. □

50.22 Chapter 22: periods of constructions

Definition 22.1 (Twists). As stated: the torus relation for every twist, every vector $\boldsymbol{\lambda}$ on the marks and all constants c_j, c_j^*.

Proof. Put $\mathbf{x}' = (c_j \boldsymbol{\lambda} \circ \mathbf{x}_j^K,\ c_j^* \boldsymbol{\lambda} \circ \mathbf{x}_j^\Psi)_j$. Every basis of table j has r_j marks and its complement r_j^*, so K_j is homogeneous of degree r_j and Ψ_j of degree r_j^*, and the letters of $F[\mathbf{x}']$ at α are

$$K_j(c_j \boldsymbol{\lambda} \circ \mathbf{x}_j^K \circ \alpha) = c_j^{r_j} K_j\big(\mathbf{x}_j^K \circ (\boldsymbol{\lambda} \circ \alpha)\big), \qquad \Psi_j(c_j^* \boldsymbol{\lambda} \circ \mathbf{x}_j^\Psi \circ \alpha) = {c_j^*}^{r_j^*} \Psi_j\big(\mathbf{x}_j^\Psi \circ (\boldsymbol{\lambda} \circ \alpha)\big).$$

Write $\omega_{\mathbf{x}} = \beta^{\mathbf{m-1}} \prod_j K_j(\mathbf{x}_j^K \circ \beta)^{-s_j} \Psi_j(\mathbf{x}_j^\Psi \circ \beta)^{-t_j}\, d\beta$ for the form of $F[\mathbf{x}]$. The map $\Phi : \alpha \mapsto \boldsymbol{\lambda} \circ \alpha$ is a linear bijection of the open orthant onto itself that commutes with positive scalings, and with $\beta_e = \lambda_e \alpha_e$ one has $\beta^{\mathbf{m-1}} d\beta = \boldsymbol{\lambda}^{\mathbf{m}} \alpha^{\mathbf{m-1}} d\alpha$. So the form of $F[\mathbf{x}']$ is

$$\omega_{\mathbf{x}'} = \boldsymbol{\lambda}^{-\mathbf{m}} \prod_j c_j^{-r_j s_j} {c_j^*}^{-r_j^* t_j}\ \Phi^* \omega_{\mathbf{x}}.$$

A twist does not change degrees, so on the balance wall both forms are homogeneous of degree zero, and each period is the integral of its form over the section $\{h = 1\}$ of any positive function h

homogeneous of degree one (8.7). Since $\int_{\{h=1\}} \Phi^* \omega_{\mathbf{x}} = \int_{\{h\circ\Phi^{-1}=1\}} \omega_{\mathbf{x}}$ and $h \circ \Phi^{-1}$ is again positive and homogeneous of degree one, the two periods differ by the constant factor of the display. The moduli of the two integrands are related by the same change of variables and a positive constant, so the two sides converge together; for real data the integrands are nonnegative and the identity holds in $[0, \infty]$.

At $\boldsymbol{\lambda} = \mu \mathbf{1}$ and $c_j = c_j^* = \mu^{-1}$ every coordinate of $\mathbf{x}'$ equals that of $\mathbf{x}$, and the factor is $\mu^{-m_{\mathcal{E}}} \mu^{\sum_j (r_j s_j + r_j^* t_j)} = 1$, since $m_{\mathcal{E}} = \sum_j (r_j s_j + r_j^* t_j)$ on the balance wall. With $\boldsymbol{\lambda}$ equal to 1 off g and to λ at g, and $c_j = c_j^* = 1$, the factor is λ^{-m_g}; with $\lambda = 1/x_1^K$ this reads every twist at g with $x_1^K = 1$, up to the factor $(x_1^K)^{-m_g}$, and for one table it leaves the one number x_1^Ψ / x_1^K, carried by the cobasis letter. With $\boldsymbol{\lambda} = \mathbf{1}$, one c_j or one c_j^* different from 1 and the other constants 1, the factor is $c_j^{-r_j s_j}$ or $c_j^{*\,-r_j^* t_j}$; for one table twisted in its cobasis letter by $\mu \mathbf{x}$ it is $\mu^{-r^* t}$. □

Remark. The reference, 22.1, rescales a twist at one mark, normalized by the scale of the mark, and the relation for one table twisted in its cobasis letter is used with 25.8. The exact check of the scalar case is check 11 of S21-23_work/checks.py.

Theorem 22.4 (The cells ride on the core's fibre). *As stated: at complex data, every exponent* 0 *or of positive real part, on contours on which the load families converge absolutely.*

Proof. The steps are those of the reference, proof of 22.4, with the moduli carried along. By 21.4, table j has the letters

$$K_j = \prod_i K_{\mathcal{A}_{ij}/g_i}(\alpha_{B_i})\, K_{\mathcal{H}_j}\big((\gamma^K_{\mathcal{A}_{ij}}(\alpha_{B_i}))_i\big), \qquad \Psi_j = \prod_i \Psi_{\mathcal{A}_{ij}\setminus g_i}(\alpha_{B_i})\, \Psi_{\mathcal{H}_j}\big((\gamma^\Psi_{\mathcal{A}_{ij}}(\alpha_{B_i}))_i\big).$$

For $\operatorname{Re} s_j > 0$, 4.4 opens $K_{\mathcal{H}_j}(X)^{-s_j} = \big(\sum_T \theta_T^{\mathcal{H}_j} X^T\big)^{-s_j}$ with one share $a_{j,T}$ per basis on a contour of positive real parts, and at $X_i = \gamma^K_{\mathcal{A}_{ij}}$ the monomials give $\prod_T (X^T)^{-a_{j,T}} = \prod_i (\gamma^K_{\mathcal{A}_{ij}})^{-a_j(h_i)}$; in the same way $\Psi_{\mathcal{H}_j}(Y)^{-t_j} = \big(\sum_T \theta_T^{\mathcal{H}_j} Y^{\{h\}\setminus T}\big)^{-t_j}$ is opened with the shares $b_{j,T}$, and $\prod_T (Y^{\{h\}\setminus T})^{-b_{j,T}} = \prod_i (\gamma^\Psi_{\mathcal{A}_{ij}})^{-b_j(h_i)}$. A letter with exponent 0 is the constant 1 and is opened by nothing. Since $\gamma^K_{\mathcal{A}} = K_{\mathcal{A}\setminus g}/K_{\mathcal{A}/g}$ and $\gamma^\Psi_{\mathcal{A}} = \Psi_{\mathcal{A}/g}/\Psi_{\mathcal{A}\setminus g}$ (21.1),

$$K^{-s_j}_{\mathcal{A}_{ij}/g_i}(\gamma^K_{\mathcal{A}_{ij}})^{-a_j(h_i)} = K^{-(s_j - a_j(h_i))}_{\mathcal{A}_{ij}/g_i} K^{-a_j(h_i)}_{\mathcal{A}_{ij}\setminus g_i}, \qquad \Psi^{-t_j}_{\mathcal{A}_{ij}\setminus g_i}(\gamma^\Psi_{\mathcal{A}_{ij}})^{-b_j(h_i)} = \Psi^{-(t_j - b_j(h_i))}_{\mathcal{A}_{ij}\setminus g_i} \Psi^{-b_j(h_i)}_{\mathcal{A}_{ij}/g_i},$$

and $e^{-|\alpha|} = \prod_i e^{-|\alpha_{B_i}|}$, so for fixed shares the integrand of J_F is the product over the cells of the integrands of the interests of the load families $F_i(\mathbf{a}, \mathbf{b})$, times the share kernels and the powers of the weights of the cores.

It remains to exchange the share integral and the integral over the orthant. For $X > 0$, $|X^{-a}| = X^{-\operatorname{Re} a}$, and $|\alpha^{\mathbf{m}-\mathbf{1}}| = \alpha^{\operatorname{Re}\mathbf{m}-\mathbf{1}}$; so the modulus of the joint integrand is

$$\prod_j \big|\Gamma_{|\substack{\mathcal{H}_j\\1}|}\begin{bmatrix}\mathbf{a}_j\\ s_j\end{bmatrix}\big|\,\big|\Gamma_{|\substack{\mathcal{H}_j\\1}|}\begin{bmatrix}\mathbf{b}_j\\ t_j\end{bmatrix}\big| \prod_{j,T} \big(\theta_T^{\mathcal{H}_j}\big)^{-\operatorname{Re}(a_{j,T}+b_{j,T})}$$

times the product of the integrands of the interests of the load families at the real parts of their data and exponents. Integrated over the orthant, the second factor gives the product of these interests at the real parts, which are finite by the hypothesis and constant along the contour, since they depend on the shares only through their real parts. On the contour, $a_{j,T} = c_{j,T} + i\tau_{j,T}$ with $c_{j,T} > 0$ fixed and $\sum_T \tau_{j,T} = \operatorname{Im} s_j$, and the classical bound $|\Gamma(c + i\tau)| \le C_c\, e^{-\pi|\tau|/2}(1 + |\tau|)^{c-1/2}$ makes $\prod_T |\Gamma(a_{j,T})|$ integrable over the imaginary parts of all shares but one; the same holds for

the shares $b_{j,T}$. So the joint integrand is absolutely integrable, the integrals may be taken in either order, and the display follows. The identity $J_{F_i(\mathbf{a},\mathbf{b})} = \Gamma(\kappa_{B_i} - \sum_j (a_j(h_i) + b_j(h_i)))\, P_{F_i(\mathbf{a},\mathbf{b})}$ is 8.7 at the imbalance of the load family: its tables $\mathcal{A}_{ij} \setminus g_i$ and $\mathcal{A}_{ij}/g_i$ have the degrees $r_{\mathcal{A}_{ij}}$, $|B_i| - r_{\mathcal{A}_{ij}}$, $r_{\mathcal{A}_{ij}} - 1$ and $|B_i| - r_{\mathcal{A}_{ij}} + 1$, and the masses $\mathbf{m}|_{B_i}$ exceed their degree by $\kappa_{B_i} - \sum_j (a_j(h_i) + b_j(h_i))$, with κ_{B_i} of 21.10. □

Theorem 22.5 (A cell read alike is pinned). *As stated: the hypothesis on every active letter, whatever the sign of its exponent.*

Proof. By 22.3, which holds for every substituted family at all data, both sides converging together,

$$P_F(\mathbf{m}; \mathbf{s}, \mathbf{t}) = \int \prod_i \beta_i(du_i)\; P_{F_{\mathcal{H}}[\boldsymbol{\gamma}(u)]}\big((\kappa_{B_i})_i; \mathbf{s}, \mathbf{t}\big),$$

β_i the cell kernels and $F_{\mathcal{H}}[\boldsymbol{\gamma}(u)]$ the core family read at u. A letter with exponent 0 is the constant 1 in every period, so the twists of the inactive letters do not enter the period of the core family read at u; give them the values $c_{ij} = 1$, $c^*_{ij} = 1$. Under the hypothesis the twists of the active letters at h_i are $c_{ij}\gamma_i(u_i)$ in K_j and $c^*_{ij}\gamma_i(u_i)$ in Ψ_j, so $F_{\mathcal{H}}[\boldsymbol{\gamma}(u)]$ has the period of $F_{\mathcal{H}}[\mathbf{c}]$ twisted further by the vector $\boldsymbol{\lambda} = (\gamma_i(u_i))_i$ on the marks of the core, in both letters of every table. The core family read at u has the imbalance of F (22.3), so it is on its balance wall, and the torus relation of 22.1 with this $\boldsymbol{\lambda}$ and constants 1 gives

$$P_{F_{\mathcal{H}}[\boldsymbol{\gamma}(u)]}\big((\kappa_{B_i})_i; \mathbf{s}, \mathbf{t}\big) = \prod_i \gamma_i(u_i)^{-\kappa_{B_i}}\, P_{F_{\mathcal{H}}[\mathbf{c}]}\big((\kappa_{B_i})_i; \mathbf{s}, \mathbf{t}\big).$$

Inserting this and integrating cell by cell gives the display, by Tonelli for real data and by Fubini where the integrals converge absolutely. The step is the reference proof of 22.5, which nowhere uses the sign of an exponent; the hypothesis there is written for the letters with positive exponent. □

Corollary 22.6 (Read by one hinge value, the period factors through the core). *As stated: for every substituted family with real data at every cell of which the active letters read the cell by one hinge value.*

Proof. (1) The first display. The hypothesis is that of 22.5 with all constants $c_{ij} = c^*_{ij} = 1$, and $F_{\mathcal{H}}[\mathbf{c}] = F_{\mathcal{H}}$; 22.5 gives the first display, in $[0, \infty]$ since the data are real. At a mark h left in place, the cell $\binom{\{h,g\}}{1}$ has both hinge values equal to α_h (21.1), so the hypothesis holds there with $\gamma = \alpha_h$.

(2) The cells. The cell family F_i has the tables $\mathcal{A}_{ij}$, cells on $|B_i| + 1$ marks of rank $r_{\mathcal{A}_{ij}}$, and by 21.10

$$\kappa_{B_i} = m_{B_i} - \sum_j \big(s_j(r_{\mathcal{A}_{ij}} - 1) + t_j(|B_i| - r_{\mathcal{A}_{ij}})\big),$$

so $m_{B_i} + 2\sigma - \kappa_{B_i} = \sum_j \big(s_j r_{\mathcal{A}_{ij}} + t_j(|B_i| + 1 - r_{\mathcal{A}_{ij}})\big)$, the degree of the family word of F_i: at the masses $(\mathbf{m}|_{B_i}, 2\sigma - \kappa_{B_i})$ it is on its balance wall. Read its period on the section $\{|\alpha_{B_i}| = 1\}$ (8.7), with $\alpha_{B_i} = u \in \Delta_{B_i}$ and $\alpha_{g_i} = v > 0$. By 21.1, $K_{\mathcal{A}_{ij}} = K_{\mathcal{A}_{ij}/g_i}(u)\big(\gamma^K_{\mathcal{A}_{ij}}(u) + v\big)$ and $\Psi_{\mathcal{A}_{ij}} = \Psi_{\mathcal{A}_{ij}\setminus g_i}(u)\big(v + \gamma^{\Psi}_{\mathcal{A}_{ij}}(u)\big)$. Under the hypothesis every active letter carries the factor $(v + \gamma_i(u))$ to the power of its exponent, and an inactive letter has exponent 0; so the word of F_i is the density of the cell kernel without $u^{\mathbf{m}|_{B_i}-\mathbf{1}}$ times $(v + \gamma_i(u))^{-2\sigma}$, $2\sigma = \sum_j (s_j + t_j)$. For $0 < \kappa < 2\sigma$ and $\gamma > 0$, the substitution $v = \gamma w$ and the Beta integral give

$$\int_0^\infty v^{2\sigma-\kappa-1}(v+\gamma)^{-2\sigma}\, dv = \gamma^{-\kappa} \int_0^\infty w^{2\sigma-\kappa-1}(1+w)^{-2\sigma}\, dw = \Gamma\,{}_2{}_1\begin{bmatrix} \kappa, & 2\sigma - \kappa \\ & 2\sigma \end{bmatrix} \gamma^{-\kappa},$$

the Beta corner of a linear letter (15.1 with one coefficient). Integrating v first (Tonelli),

$$P_{F_i}\big((\mathbf{m}|_{B_i}, 2\sigma-\kappa_{B_i}); \mathbf{s}, \mathbf{t}\big) = \Gamma_1^2\begin{bmatrix}\kappa_{B_i}, & 2\sigma-\kappa_{B_i}\\ & 2\sigma\end{bmatrix}\int_{\Delta_{B_i}} \gamma_i^{-\kappa_{B_i}}\, d\beta_i,$$

which identifies the pinned shape integral.

(3) The walls. The marks of a core are neither loops nor coloops (21.1), so a core has at least two marks, $q \geq 2$, and B_i is a nonempty proper set of marks; it has width one in every table (21.3(i)). Width one in table j means $d_j(B_i)+d_j(\mathcal{E}\setminus B_i) = r_j - 1$ and $d_j^*(B_i)+d_j^*(\mathcal{E}\setminus B_i) = r_j^* - 1$, so

$$\kappa_{B_i} + \kappa_{\mathcal{E}\setminus B_i} = m_{\mathcal{E}} - \sum_j \big(s_j(r_j-1) + t_j(r_j^*-1)\big) = \kappa_{\mathcal{E}} + 2\sigma,$$

which is 2σ on the balance wall (21.12; check 2 of S21-23_work/checks.py). If every proper wall is positive, $\kappa_{B_i} > 0$ and $\kappa_{\mathcal{E}\setminus B_i} > 0$, so $0 < \kappa_{B_i} < 2\sigma$.

(4) The second display. Multiply the first display by $\prod_i \Gamma_1^2\begin{bmatrix}\kappa_{B_i}, & 2\sigma-\kappa_{B_i}\\ & 2\sigma\end{bmatrix} \in (0,\infty)$ and use step (2). The left side is finite (8.7), every factor on the right lies in $(0,\infty]$, so every factor is finite. The core family at $(\kappa_{B_i})_i$ has the imbalance of F (22.3), the cell families are balanced by step (2), and a family on its balance wall with a finite period has every proper wall positive (8.7).

(5) One cell. With one cell at h_1 and the other marks of the core left in place, the left-in-place cell family at h, the list $\binom{\{h,g\}}{1}$ in every table with the masses $(m_h, 2\sigma-m_h)$, has the word $(\alpha_h+\alpha_g)^{-2\sigma}$ and the period $\Gamma_1^2\begin{bmatrix}m_h, & 2\sigma-m_h\\ & 2\sigma\end{bmatrix}$, while $\kappa_{\{h\}} = m_h$; these factors cancel the Beta corners of the marks left in place. The core family is then the family of the cells of the room at the masses $(\kappa_B, \mathbf{m}|_R)$ and F_1 that of the cells of the bunch (21.3(iii)), and the second display is the identity of 19.10. In the first display the marks left in place contribute 1, their simplex being a point and their kernel the constant 1, and it is the identity of 19.12 with all constants 1. □

Remark. The reference proof (22.6, one table at $(0,t)$) uses of the full lean only that the letter which sees the cells sees each through one function. A family at mixed full leans is covered: on $B=\{1,2\}$ let table 1 at $(s_1,0)$ carry the series block $\binom{\{1,2,g\}}{2}$ and table 2 at $(0,t_2)$ the parallel block $\binom{\{1,2,g\}}{1}$. Both active letters read B through e_2/e_1 (21.7(i)), $\kappa_B = m_B - 2\sigma$, the cell family has the word $e_2(\alpha_1,\alpha_2,\alpha_g)^{-2\sigma}$ and the period $\Gamma(2\sigma-m_1)\Gamma(2\sigma-m_2)\Gamma(\kappa_B)/\Gamma(2\sigma)$ (26.9), and the pinned shape integral is $\int_0^1 u^{m_1-1}(1-u)^{m_2-1}(u(1-u))^{-\kappa_B}du = \Gamma(2\sigma-m_1)\Gamma(2\sigma-m_2)/\Gamma(4\sigma-m_B)$, whose quotient is $\Gamma_1^2\begin{bmatrix}\kappa_B, & 2\sigma-\kappa_B\\ & 2\sigma\end{bmatrix}$, as step (2) says. At $(2\sigma, m_1, m_2) = (3,2,2)$ the period is $\frac{1}{2}$, and the identity holds exactly there and at $(\frac{7}{2},\frac{3}{2},\frac{5}{2})$ (checks 7a to 7d of S21-23_work/checks.py).

Corollary 22.7 (The pinned shape integral is the period of a load family). *As stated.*

Proof. A load $a_{ij} \neq 0$ occurs only where $s_j \neq 0$, where $\gamma^K_{\mathcal{A}_{ij}} = K_{\mathcal{A}_{ij}\setminus g_i}/K_{\mathcal{A}_{ij}/g_i} = \gamma_i$, and a load $b_{ij} \neq 0$ only where $t_j \neq 0$, where $\gamma^\Psi_{\mathcal{A}_{ij}} = \Psi_{\mathcal{A}_{ij}/g_i}/\Psi_{\mathcal{A}_{ij}\setminus g_i} = \gamma_i$ (21.1). Since $\sum_j(a_{ij}+b_{ij}) = \kappa_{B_i}$,

$$\gamma_i^{-\kappa_{B_i}}\prod_j K^{-s_j}_{\mathcal{A}_{ij}/g_i}\Psi^{-t_j}_{\mathcal{A}_{ij}\setminus g_i} = \prod_j K^{-a_{ij}}_{\mathcal{A}_{ij}\setminus g_i}\Psi^{-(t_j-b_{ij})}_{\mathcal{A}_{ij}\setminus g_i}K^{-(s_j-a_{ij})}_{\mathcal{A}_{ij}/g_i}\Psi^{-b_{ij}}_{\mathcal{A}_{ij}/g_i},$$

the word of the load family, whose imbalance $\kappa_{B_i} - \sum_j(a_{ij}+b_{ij})$ is zero (22.4). Its period is the integral of $u^{\mathbf{m}|_{B_i}-\mathbf{1}}$ times its word over the shape simplex (8.7), the pinned shape integral, and the

product formula is 22.6. If every proper wall of F is positive, then $0 < \kappa_{B_i} < 2\sigma = \sum_j (s_j + t_j)$ (22.6); with $s_j, t_j \geq 0$, raising the loads one after another from 0, each up to its bound s_j or t_j and only on the active letters, reaches the total κ_{B_i}, and at integer data κ_{B_i} is an integer (21.10) and the loads can be integers. The exponents a_{ij}, $t_j - b_{ij}$, $s_j - a_{ij}$ and b_{ij} are then nonnegative. When P_F is finite every factor of the product formula is finite, the factors being positive, and the load family, on its balance wall, has every proper wall positive (8.7). □

Theorem 22.8 (A chain is the power of one operator). *As stated: at real exponents, the pinned case for the active letters.*

Proof. The reference proof of 22.8 applies verbatim at real exponents. It uses pooling (19.8, for every family at all data, both sides converging together), the nonnegativity of the integrands (at real exponents the letters are positive, and so is every power of them), the scalar twist of a mark (22.1) and the Beta integral $\int_0^1 v^{m_{g_{\mathrm{in}}}-1}(1-v)^{m_{g_{\mathrm{out}}}-1}(1-v+\lambda v)^{-2\sigma}dv = \lambda^{-m_{g_{\mathrm{in}}}}\Gamma\,{}_2{}_1\!\left[\begin{matrix} m_{g_{\mathrm{in}}},\ m_{g_{\mathrm{out}}} \\ 2\sigma \end{matrix}\right]$ at $m_{g_{\mathrm{in}}} + m_{g_{\mathrm{out}}} = 2\sigma$; none of these uses the sign of an exponent. In the pinned case the reference assumes that all the active letters read the cell through one function; a letter of exponent 0 is absent from every period, which is the hypothesis as stated. □

Theorem 22.9 (Letters by transfer). *As stated: the reduction of the states to linearly independent ones, and the bound on the interface dimension for a multivector of any tensor rank.*

Proof. The products of transfer matrices are the reference's. *The stations.* The stations of level k of S_l give a level factorization with as many terms (the children factorization, 21.15), so their number is at least $\operatorname{rank}\Theta^{(k)}_{S_l}$, and the number of states is at least the interface dimension.

The reduction. The child of a pattern p of S_l at level k is $\sum_X \theta_{p\sqcup X}\alpha^X$, the polynomial of the row p of $\Theta^{(k)}_{S_l}$, so the children of level k span a space of dimension $\operatorname{rank}\Theta^{(k)}_{S_l}$. Splitting X along the step B_{l-1}, the child at p of S_{l-1} is

$$\sum_X \theta_{p\sqcup X}\alpha^X = \sum_{p'\subseteq B_{l-1}} \alpha^{p'} \sum_{X'} \theta_{(p\sqcup p')\sqcup X'}\alpha^{X'},$$

the sum over p' of $\alpha^{p'}$ times the child at $p\sqcup p'$ of S_l. Choose at every S_l and every level a basis of the span of the children and write every child in it; the display expresses each basis element at S_{l-1}, a combination of children of S_{l-1}, through the basis elements at S_l, with coefficients polynomial in $\alpha_{B_{l-1}}$. These are transfer matrices on $\sum_k \operatorname{rank}\Theta^{(k)}_{S_l}$ states at S_l, and the products give K; the same coefficients, read on the complements, give Ψ (21.15).

The bound. By 21.17(i), $\operatorname{rank}\Theta^{(k)}_{S_l} \leq \operatorname{ir}_k(\boldsymbol{\omega})^2$, and $\leq \frac{1}{2}\operatorname{ir}_k(\boldsymbol{\omega})(\operatorname{ir}_k(\boldsymbol{\omega})+1)$ when $\boldsymbol{\omega}$ is real; by (ii), $\operatorname{ir}_k(\boldsymbol{\omega}) \leq \sum_i \binom{c_i}{k-d_i}$. The functions $q \mapsto q^2$ and $q \mapsto \frac{1}{2}q(q+1)$ increase on $[0,\infty)$, and summing over k gives the bound. For a determinantal table, of tensor rank one with $c_1 = c(S_l)$ and $d_1 = d(S_l)$ (21.17(ii)), the bound is $\sum_m \binom{c}{m}^2 = \binom{2c}{c}$, $c = c(S_l)$, counting the c-subsets of a set of $2c$ elements by their intersection with a fixed half. □

Theorem 22.10 (Integer joint moments by fixed matrices). *As stated: all the letters of a family at once, along a chain of bunches with any steps and any independent measures on them.*

Proof. This is the reference proof of 22.10 with the tensor product taken over all the tables and with one matrix per step. A product of scalars $\mathbf{u}_i^{\mathsf{T}} A_{i,0}\cdots A_{i,L-1}\mathbf{v}_i$, $i = 1,\dots,n$, equals $(\bigotimes_i \mathbf{u}_i)^{\mathsf{T}}\big(\bigotimes_i A_{i,0}\big)\cdots\big(\bigotimes_i A_{i,L-1}\big)(\bigotimes_i \mathbf{v}_i)$ by the mixed-product rule $(\bigotimes_i A_i)(\bigotimes_i B_i) =$

$\bigotimes_i (A_i B_i)$. Apply it to the a_j copies of K_j and the b_j copies of Ψ_j for every j: the factor of the step l is $\bigotimes_j \big(\mathbf{M}^K_{j,l}(\alpha_{B_l})^{\otimes a_j} \otimes \mathbf{M}^\Psi_{j,l}(\alpha_{B_l})^{\otimes b_j}\big)$, a matrix function of α_{B_l} alone. Every entry of the product is a finite sum of products of one entry of each step factor; the measures of the steps are independent, so the integral of such a product is the product of the integrals, by Tonelli for nonnegative entries and by Fubini under the stated finiteness, and integrating entrywise replaces the factor of the step l by $\mathbf{A}_l$.

For identical steps every $\mathbf{A}_l$ is one matrix $\mathbf{A}$ of the stated size, and the scalars $\mathbf{u}^\top \mathbf{A}^L \mathbf{v}$ satisfy the linear recurrence whose coefficients are those of the characteristic polynomial of $\mathbf{A}$, which annihilates $\mathbf{A}$. With independent laws Gamma_{m_x} on the marks, $\prod_j K_j^{a_j} \Psi_j^{b_j}$ is homogeneous of degree $d = \sum_j (a_j r_j + b_j r_j^*)$, and the draw splits into an independent total of law $\mathrm{Gamma}_{m_\mathcal{E}}$ and a shape of law $\mathrm{Dir}_\mathbf{m}$ (8.12(ii)), the total having the moment $(m_\mathcal{E})_d$ of order d. With $\mathrm{Dir}_{\mathbf{m}|_{B_l}}$ on a step, the entries of $\mathbf{A}_l$ are the Dirichlet moments of the monomials (3.11). □

Theorem 22.11 (Gluing across a bunch of any width). *As stated: the share display for one table at a full lean at every width, and the count* $2N-1$ *of the free shares at width one.*

Proof. The main display is the reference's. For one table at the full lean $(0,t)$ in level form, one station per level, the active letter Ψ has the $c(B)+1$ terms of the levels $k = d(B), \dots, r(B)$, so the stacked Gamma of the display is $\prod_k \Gamma(b_k)/\Gamma(t)$ and the pins are $\sum_k b_k = t$ and $\sum_k (r(B)-k) b_k = \kappa_B$, the main pin without the shares of K. The fibre integral (4.1) has $c(B)+1$ shares and two pins. Integrating the delta of the pins against the imaginary parts of $b_{d(B)}$ and $b_{r(B)}$ divides by $|\det|$ of the matrix of the two pins in these shares,

$$\begin{pmatrix} 1 & 1 \\ c(B) & 0 \end{pmatrix}, \qquad |\det| = c(B)$$

(check 8a of S21-23_work/checks.py), and leaves $(2\pi)^{2-(c(B)+1)}$ times the integral over the imaginary parts of the $c(B)-1$ free shares, which is $\frac{1}{(2\pi i)^{c(B)-1}} \int \prod db_k$. The pins solved for $b_{d(B)}$ and $b_{r(B)}$ give the stated values; at $c(B)=2$ they are $\frac{\kappa_B - z}{2}$ and $\frac{2t-\kappa_B-z}{2}$ with $b_{d(B)+1} = z$ (check 8b). At $c(B)=1$ the fibre has dimension 0, the matrix of the pins has $|\det| = 1$, and the integral is the value at $(b_{d(B)}, b_{r(B)}) = (\kappa_B, t-\kappa_B)$, the Beta corner times the two inner periods, which is 19.14: the bunch and room letters of the two levels are the minors $\Psi_{\mathcal{B}/R}, \Psi_{\mathcal{B}|B}$ and $\Psi_{\mathcal{B}|R}, \Psi_{\mathcal{B}/B}$ up to constant factors of the factorization that cancel in the product. At width one with factoring weights each level has one station (12.19), so each of the $2N$ active letters has two terms, and the free shares are $4N - 2N - 1 = 2N-1$, the dimension of the fibre integral of 19.13, of which the main display is then the formula. □

Remark. The paragraph after 22.11 gives the Mellin transform of the scale integral $I(\boldsymbol{\zeta}) = \int_0^\infty x^{\kappa_B - 1} \big(1 + \sum_{i=1}^{c-1} \zeta_i x^i + x^c\big)^{-t} dx$, $c = c(B)$. By Tonelli and the substitutions $\zeta_i = \eta_i x^{-i}$, then $x^c = w$,

$$\int \prod_i \zeta_i^{z_i - 1} I(\boldsymbol{\zeta})\, d\boldsymbol{\zeta} = \frac{\prod_i \Gamma(z_i)\, \Gamma(t - \sum_i z_i)}{\Gamma(t)} \int_0^\infty x^{\kappa_B - \sum_i i z_i - 1} (1+x^c)^{\sum_i z_i - t} dx = \frac{\prod_{k=d(B)}^{r(B)} \Gamma(b_k)}{c\, \Gamma(t)}$$

at $b_{r(B)-i} = z_i$, $b_{d(B)} = (\kappa_B - \sum_i i z_i)/c$ and $b_{r(B)} = t - b_{d(B)} - \sum_i z_i$, wherever these have positive real parts: the share kernel of the theorem with the factor $1/c$ of the pin.

50.23 Chapter 23: the law of a cell

Definition 23.1 (The law of a cell family). As stated: the Mellin transform of the law of a cell family, and the transforms and the hinge measures of a cell family, those of one cell being their readings.

Proof. The definition asserts three things. *The Mellin transform.* For complex $\mathbf{z}$ and real positive coordinates, $|\boldsymbol{\varrho}_F^{-\mathbf{z}}| = \boldsymbol{\varrho}_F^{-\operatorname{Re}\mathbf{z}}$, so the integral converges absolutely where it is finite at the real part, with modulus at most that value; for one cell $\boldsymbol{\varrho}_F^{-\mathbf{z}} = (\gamma_{\mathcal{A}}^{\Psi}/\gamma_{\mathcal{A}}^{K})^{-z_{1,\Psi}} = \varrho_{\mathcal{A}}^{-z}$, and the second form is the image of the measure. The base form of one cell is ϕ_F with $(\gamma_{\mathcal{A}}^{K})^{-\kappa} = K_{\mathcal{A}/g}^{\kappa} K_{\mathcal{A}\setminus g}^{-\kappa}$.

Homogeneity. Substitute $\alpha = c\beta$ in the orthant forms: $\alpha^{\mathbf{m}-\mathbf{1}} d\alpha = c^{m_B} \beta^{\mathbf{m}-\mathbf{1}} d\beta$, the letters of the deletions have the degrees $r_{\mathcal{A}_j}$ and $|B| - r_{\mathcal{A}_j}$, those of the contractions $r_{\mathcal{A}_j} - 1$ and $|B| - r_{\mathcal{A}_j} + 1$, and the hinge values have degree one. So

$$f_F(\mathbf{x}, \mathbf{y}) = c^{m_B - \sum_j (s_j r_{\mathcal{A}_j} + t_j(|B| - r_{\mathcal{A}_j}))} f_F(\mathbf{x}/c, c\mathbf{y}) = c^{\kappa_F - |\mathbf{s}|} f_F(\mathbf{x}/c, c\mathbf{y}),$$

and in the same way $\check{f}_F(\mathbf{x}, \mathbf{y}) = c^{\kappa_F - |\mathbf{t}|} \check{f}_F(\mathbf{x}/c, c\mathbf{y})$. With $c = x_1$ each transform is fixed by its values at $x_1 = 1$.

One cell. At $N = 1$, $f_F(1, y)$ and $\check{f}_F(1, y)$ are the integrals called the orthant forms of the transforms of one cell, and the images of $e^{-\lambda} \mathfrak{r}_F$ and $e^{-\lambda} \check{\mathfrak{r}}_F$ under $(\lambda, \mu) \mapsto \mu$ are the images of $\alpha^{\mathbf{m}-\mathbf{1}} K_{\mathcal{A}\setminus g}^{-s} \Psi_{\mathcal{A}\setminus g}^{-t} e^{-1/\gamma_{\mathcal{A}}^{K}} d\alpha$ under $\gamma_{\mathcal{A}}^{\Psi}$ and of $\alpha^{\mathbf{m}-\mathbf{1}} K_{\mathcal{A}/g}^{-s} \Psi_{\mathcal{A}/g}^{-t} e^{-1/\gamma_{\mathcal{A}}^{\Psi}} d\alpha$ under $\gamma_{\mathcal{A}}^{K}$. □

Theorem 23.3 (The series closure at positive exponents). *As stated: the closure through the transforms of the cell families, each transform one Gramma of index $|\mathbf{s}| - \kappa_{B_i}$ at every data, and its Breta shape reading wherever the family of the hinge minors is balanced.*

Proof. The closure. The responses of the reference, proof and statement of 23.3, are the integrals over $\mathbb{R}_{>0}^{B_i}$ of $\alpha^{\mathbf{m}|_{B_i}-\mathbf{1}} \prod_j K_{\mathcal{A}_{ij}\setminus g_i}^{-s_j} \Psi_{\mathcal{A}_{ij}\setminus g_i}^{-t_j}$ against $\exp\big(- \sum_j x_j K_{\mathcal{A}_{ij}/g_i}/K_{\mathcal{A}_{ij}\setminus g_i} - \sum_j y_j \Psi_{\mathcal{A}_{ij}/g_i}/\Psi_{\mathcal{A}_{ij}\setminus g_i}\big)$ with $y_1 = 1$; since $K_{\mathcal{A}/g}/K_{\mathcal{A}\setminus g} = 1/\gamma_{\mathcal{A}}^{K}$ and $\Psi_{\mathcal{A}/g}/\Psi_{\mathcal{A}\setminus g} = \gamma_{\mathcal{A}}^{\Psi}$, they are the transforms $f_{F_i}(\mathbf{x}, (1, y_2, \dots, y_N))$ of 23.1, and the first display is the reference's. The statement on repeated cells is read off the product.

One table. By the homogeneity of 23.1 with $c = x$, $f_{F_i}(x, 1) = x^{\kappa_{B_i} - s} f_{\mathcal{A}_i}(x)$. The core $\binom{\{h_1,\dots,h_q\}}{q-1}$ has rank $q - 1$ and corank 1, and the core family read at u is balanced (22.3), so $\sum_i \kappa_{B_i} = (q-1)s + t$. The power of x is then $x^{s-1+(q-1)s+t-qs} = x^{t-1}$, and the closure is $\frac{1}{\Gamma(s)\Gamma(t)} \int_0^{\infty} x^{t-1} \prod_i f_{\mathcal{A}_i}(x)\, dx$.

The Gramma. Fix i and write $\alpha = \rho u$, $u \in \Delta_{B_i}$, $\rho > 0$, so that $\alpha^{\mathbf{m}|_{B_i}-\mathbf{1}} d\alpha = \rho^{m_{B_i}-1} u^{\mathbf{m}|_{B_i}-\mathbf{1}} d\rho\, d\omega$ (2.7). The marks g_i being neither loops nor coloops, $K_{\mathcal{A}_{ij}\setminus g_i}$ is homogeneous of degree $r_{\mathcal{A}_{ij}}$ and $\Psi_{\mathcal{A}_{ij}\setminus g_i}$ of degree $|B_i| - r_{\mathcal{A}_{ij}}$, and the hinge values of degree one. So the power of ρ is $\rho^{\nu-1}$ with

$$\nu = m_{B_i} - \sum_j \big(s_j r_{\mathcal{A}_{ij}} + t_j(|B_i| - r_{\mathcal{A}_{ij}})\big) = \kappa_{B_i} - |\mathbf{s}|,$$

and the exponential is $\exp(-a(u)/\rho - b(u)\rho)$ with $a = \sum_j x_j/\gamma_{\mathcal{A}_{ij}}^{K}$ and $b = \sum_j y_j \gamma_{\mathcal{A}_{ij}}^{\Psi}$. By 2.1 and the reflection (2.3),

$$\int_0^{\infty} \rho^{\nu-1} e^{-b\rho - a/\rho}\, d\rho = \mathsf{G}_{\nu;(1,-1)}(b, a) = \mathsf{G}_{-\nu;(1,-1)}(a, b),$$

and Tonelli gives the display of the transform.

Index 0. The family of the hinge minors has the degree $\sum_j \big(s_j r_{\mathcal{A}_{ij}} + t_j(|B_i| - r_{\mathcal{A}_{ij}})\big)$ at the masses $\mathbf{m}|_{B_i}$, so it is on its balance wall exactly when $\kappa_{B_i} = |\mathbf{s}|$; at the centre of one table, every mass σ and $s = t = \sigma$, $\kappa_{B_i} = \sigma|B_i| - \sigma(r-1) - \sigma(|B_i| - r) = s$. Torus homogeneity (2.4(iii)) with $\lambda = a$ gives $\mathsf{G}_{0;(1,-1)}(a,b) = \mathsf{G}_{0;(1,-1)}(1,ab)$. With every proper wall positive, the form of the family of the hinge minors divided by its period is its Breta shape law (8.10), which gives the expectation; for one table, $ab = xy\,\gamma^{\Psi}_{\mathcal{A}_i}/\gamma^{K}_{\mathcal{A}_i} = xy\varrho_{\mathcal{A}_i}$. The period of k copies is the first display with all F_i equal. □

Theorem 23.6 (The law of a substitution). *As stated: (i) and (ii) for families at real data; the present (i) was the gluing of a family, and (ii) for one table at $s, t > 0$.*

Proof. (ii) This is the reference proof of 23.6(ii) with the index j, the steps being those of 23.2 applied to one cell family after another. Write $B = \mathcal{E}_{\mathcal{H}} \sqcup \bigsqcup_i B_i$ and $\mathcal{A}_j = \mathcal{H}_j\langle \mathcal{A}_{1j}, \dots, \mathcal{A}_{kj}\rangle$, a cell with the hinge g_0 (23.5). For a Borel $H \geq 0$, $\int H\, d((\boldsymbol{\varrho}_F)_*\phi_F)$ is the integral over the section $\{|\alpha| = 1\}$ of the orthant form

$$\omega = \alpha^{\mathbf{m-1}} H(\boldsymbol{\varrho}_F)\, K_{\mathcal{A}_1/g_0}^{\kappa_F - s_1} K_{\mathcal{A}_1\setminus g_0}^{-\kappa_F} \prod_{j\geq 2} K_{\mathcal{A}_j/g_0}^{-s_j} \prod_j \Psi_{\mathcal{A}_j\setminus g_0}^{-t_j}\, d\alpha,$$

homogeneous of degree $m_B - \sum_j \big(s_j(r_{\mathcal{A}_j} - 1) + t_j(|B| - r_{\mathcal{A}_j})\big) - \kappa_F = 0$, the base form being $u^{\mathbf{m-1}} \prod_j K_{\mathcal{A}_j/g_0}^{-s_j} \Psi_{\mathcal{A}_j\setminus g_0}^{-t_j} (K_{\mathcal{A}_1\setminus g_0}/K_{\mathcal{A}_1/g_0})^{-\kappa_F} d\omega$. By 23.5, with the hinge values of the cells at their own marks,

$$K_{\mathcal{A}_j\setminus g_0} = \prod_i K_{\mathcal{A}_{ij}/g_i}\, K_{\mathcal{H}_j\setminus g_0}\big(\alpha_{\mathcal{E}_{\mathcal{H}}}, (\gamma^K_{\mathcal{A}_{ij}})_i\big), \qquad K_{\mathcal{A}_j/g_0} = \prod_i K_{\mathcal{A}_{ij}/g_i}\, K_{\mathcal{H}_j/g_0}\big(\alpha_{\mathcal{E}_{\mathcal{H}}}, (\gamma^K_{\mathcal{A}_{ij}})_i\big),$$

and the same for Ψ with $\prod_i \Psi_{\mathcal{A}_{ij}\setminus g_i}$ and the hinge values $\gamma^{\Psi}_{\mathcal{A}_{ij}}$. The products over the cells cancel in the quotients, so the hinge values of $\mathcal{A}_j$ at g_0 are those of $\mathcal{H}_j$ read at $(\alpha_{\mathcal{E}_{\mathcal{H}}}, (\gamma^K_{\mathcal{A}_{ij}})_i)$ and $(\alpha_{\mathcal{E}_{\mathcal{H}}}, (\gamma^{\Psi}_{\mathcal{A}_{ij}})_i)$.

Apply 23.2 to F_1 with $Z = \mathcal{E}_{\mathcal{H}} \sqcup \bigsqcup_{i\geq 2} B_i$. Assign to the letter $K_{\mathcal{A}_{1j}}$ the functions $\prod_{i\geq 2} K_{\mathcal{A}_{ij}/g_i} \cdot K_{\mathcal{H}_j/g_0}$ and $\prod_{i\geq 2} K_{\mathcal{A}_{ij}/g_i} \cdot K_{\mathcal{H}_j\setminus g_0}$, read at the hinge value of the cell at g_1, with the exponents s_j and 0 for $j \geq 2$ and $s_1 - \kappa_F$ and κ_F for $j = 1$; and to the letter $\Psi_{\mathcal{A}_{1j}}$ the functions $\prod_{i\geq 2} \Psi_{\mathcal{A}_{ij}\setminus g_i} \cdot \Psi_{\mathcal{H}_j\setminus g_0}$ and $\prod_{i\geq 2} \Psi_{\mathcal{A}_{ij}\setminus g_i} \cdot \Psi_{\mathcal{H}_j/g_0}$ with the exponents t_j and 0. The exponents assigned to each letter add to its exponent, the letters of the hinge minors of F_1 collect to $K_{\mathcal{A}_{1j}/g_1}^{-s_j} \Psi_{\mathcal{A}_{1j}\setminus g_1}^{-t_j}$, the product of the assigned powers is the rest of ω, and $H(\boldsymbol{\varrho}_F)$ is a Borel function of the values of the assigned functions, which give the hinge values of every $\mathcal{A}_j$ as quotients. The lemma collapses B_1 to g_1 with the mass κ_{F_1} and replaces the hinge values of the cells at g_1 by $x_{1,j,K}\alpha_{g_1}$ and $x_{1,j,\Psi}\alpha_{g_1}$, the twist at g_1 by the point $\mathbf{x}_1$ of the law of F_1. Repeat for $F_2, \dots, F_k$, moving the integrals over the laws outside (Tonelli). What remains is the integral over a section of the form of the cell family $F_{\mathcal{H}}[\mathbf{x}]$, its hinge minors at g_0 read with the twists, its masses $\mathbf{m}|_{\mathcal{E}_{\mathcal{H}}}$ and κ_{F_i}, the power κ_F in place of its hinge wall, and H of its ratio vector inserted. Its hinge wall is

$$m_{\mathcal{E}_{\mathcal{H}}} + \sum_i \kappa_{F_i} - \sum_j \big(s_j(r_{\mathcal{H}_j} - 1) + t_j(|\mathcal{E}_{\mathcal{H}}| + k - r_{\mathcal{H}_j})\big),$$

and it equals κ_F: insert $\kappa_{F_i} = m_{B_i} - \sum_j (s_j(r_{\mathcal{A}_{ij}} - 1) + t_j(|B_i| - r_{\mathcal{A}_{ij}}))$, $r_{\mathcal{A}_j} = r_{\mathcal{H}_j} + \sum_i (r_{\mathcal{A}_{ij}} - 1)$ and $|B| = |\mathcal{E}_{\mathcal{H}}| + \sum_i |B_i|$ (23.5); the coefficients of s_j and of t_j agree term by term (check 1 of S21-23_work/checks.py). So the remaining integral is $\int H\, d((\boldsymbol{\varrho}_{F_{\mathcal{H}}[\mathbf{x}]})_*\phi_{F_{\mathcal{H}}[\mathbf{x}]})$, and the mixture follows;

the hinge wall does not depend on $\mathbf{x}$. With $H = \boldsymbol{\varrho}^{-\mathbf{z}}$, a nonnegative Borel function for real $\mathbf{z}$, the Mellin transforms mix in the same way.

(i) The same steps with the family word of F in place of the base form: on the balance wall the form of F is homogeneous of degree zero, its letters are $\prod_i K_{\mathcal{A}_{ij}/g_i} \cdot K_{\mathcal{H}_j}$ and $\prod_i \Psi_{\mathcal{A}_{ij}\setminus g_i} \cdot \Psi_{\mathcal{H}_j}$ read at the hinge values (23.5), the factors $K_{\mathcal{H}_j}$ and $\Psi_{\mathcal{H}_j}$ are assigned to the letters of each cell family in turn with the exponents s_j and t_j, and 23.2 collapses every cell to its marker with the mass κ_{F_i} and the twist by the point of its law. This is the reference's remark on families (rem:familiesnodes): 23.2 holds at real exponents, its proof collecting degrees and using Tonelli. For the core $\binom{\{g_1,g_2\}}{1}$, twisted at g_1 by $\mathbf{x}_1$ and at g_2 by $\mathbf{x}_2$, table j has $K_j = x_{1,j,K}\alpha_{g_1} + x_{2,j,K}\alpha_{g_2}$ and $\Psi_j = x_{1,j,\Psi}\alpha_{g_1} + x_{2,j,\Psi}\alpha_{g_2}$, and on the section $\alpha_{g_2} = 1$ its period is the displayed integral, a Breta of one bunch (15.1); the substitution $v \mapsto 1/v$ multiplies the integrand by $v^{2\sigma}$ and turns $v^{\kappa_{F_1}-1}dv$ into $v^{-\kappa_{F_1}-1}dv$, which gives the swap since $\kappa_{F_1} + \kappa_{F_2} = 2\sigma$. □

Proposition 23.8 (Faces of one law). *As stated, for every cell family with plain tables and $s_j, t_j > 0$.*

Proof. Write $\kappa = \kappa_F$ and γ_j^K, γ_j^Ψ for the hinge values of $\mathcal{A}_j$. The reference proof of 23.8 is the case $N = 1$; the steps below are that proof with the index j, the changes being the bookkeeping of the powers of γ_1^K and γ_1^Ψ, which pass the integrals from the simplex to the law.

(i) In the orthant form of f_F write $\alpha = \rho u$ (2.7). As in the proof of 23.3 in this part, the power of ρ is $\rho^{\kappa-|\mathbf{s}|-1}$ and

$$f_F(\mathbf{x},\mathbf{y}) = \int_{\Delta_B} \mathsf{G}_{|\mathbf{s}|-\kappa;(1,-1)}\Big(\sum_j \frac{x_j}{\gamma_j^K(u)},\ \sum_j y_j\gamma_j^\Psi(u)\Big)\, u^{\mathbf{m}-\mathbf{1}} \prod_j K_{\mathcal{A}_j\setminus g}^{-s_j}\Psi_{\mathcal{A}_j\setminus g}^{-t_j}\, d\omega(u).$$

Since $K_{\mathcal{A}_j\setminus g} = \gamma_j^K K_{\mathcal{A}_j/g}$, the measure is $(\gamma_1^K)^\kappa \prod_j (\gamma_j^K)^{-s_j}\phi_F = (\gamma_1^K)^{\kappa-|\mathbf{s}|}\prod_j(\gamma_j^K/\gamma_1^K)^{-s_j}\phi_F$. Torus homogeneity (2.4(iii)) with $\lambda = 1/\gamma_1^K$, $\mathsf{G}_{\nu;(1,-1)}(\lambda\xi_1,\xi_2/\lambda) = \lambda^{-\nu}\mathsf{G}_{\nu;(1,-1)}(\xi_1,\xi_2)$, gives, at $\mathbf{z} = \boldsymbol{\varrho}_F(u)$,

$$\mathsf{G}_{|\mathbf{s}|-\kappa;(1,-1)}\Big(\sum_j \frac{x_j}{\gamma_j^K},\ \sum_j y_j\gamma_j^\Psi\Big) = (\gamma_1^K)^{|\mathbf{s}|-\kappa}\,\mathsf{G}_{|\mathbf{s}|-\kappa;(1,-1)}\Big(\sum_j \frac{x_j}{z_{j,K}},\ \sum_j y_j z_{j,\Psi}\Big).$$

The powers of γ_1^K cancel, and the image under $\boldsymbol{\varrho}_F$ gives the first law form. For $\check{f}_F$ the contracted letters have the degrees $r_{\mathcal{A}_j} - 1$ and $|B| - r_{\mathcal{A}_j} + 1$, so the power of ρ is $\rho^{\kappa-|\mathbf{t}|-1}$, the index is $|\mathbf{t}| - \kappa$, and the coefficients are $\sum_j x_j/\gamma_j^\Psi$ and $\sum_j y_j\gamma_j^K$; the measure is $u^{\mathbf{m}-\mathbf{1}}\prod_j K_{\mathcal{A}_j/g}^{-s_j}\Psi_{\mathcal{A}_j/g}^{-t_j}d\omega = (\gamma_1^K)^\kappa\prod_j(\gamma_j^\Psi)^{-t_j}\phi_F$, since $\Psi_{\mathcal{A}_j/g} = \gamma_j^\Psi\Psi_{\mathcal{A}_j\setminus g}$. Torus homogeneity with $\lambda = 1/\gamma_1^\Psi$ extracts $(\gamma_1^\Psi)^{|\mathbf{t}|-\kappa}$, and $(\gamma_1^K)^\kappa\prod_j(\gamma_j^\Psi)^{-t_j}(\gamma_1^\Psi)^{|\mathbf{t}|-\kappa} = z_{1,\Psi}^{-\kappa}\prod_j(z_{j,\Psi}/z_{1,\Psi})^{-t_j}$, with $z_{1,\Psi}/z_{j,\Psi} = \gamma_1^\Psi/\gamma_j^\Psi$ and $z_{j,K}/z_{1,\Psi} = \gamma_j^K/\gamma_1^\Psi$: the second law form. At $N = 1$, $z_{1,K} = 1$, $z_{1,\Psi} = \varrho_{\mathcal{A}}$ and $\mathbf{x} = 1$ give $\mathsf{G}_{s-\kappa;(1,-1)}(1,\varrho_{\mathcal{A}}y)$ and $\mathsf{G}_{t-\kappa;(1,-1)}(1,y/\varrho_{\mathcal{A}})\varrho_{\mathcal{A}}^{-\kappa}$.

(ii) The Laplace forms are the definitions of the images. For the law form of $\mathfrak{r}_F$ write $\alpha = \rho u$ and $p = \rho\gamma_1^K(u)$: then $1/\gamma_j^K(\alpha) = 1/(pz_{j,K})$ and $\gamma_j^\Psi(\alpha) = pz_{j,\Psi}$ at $\mathbf{z} = \boldsymbol{\varrho}_F(u)$, and $\rho^{\kappa-|\mathbf{s}|-1}d\rho = (\gamma_1^K)^{|\mathbf{s}|-\kappa}p^{\kappa-|\mathbf{s}|-1}dp$, which with the measure of (i) leaves $\prod_j z_{j,K}^{-s_j}\phi_F(du)\otimes p^{\kappa-|\mathbf{s}|-1}dp$. A Laplace transform of a positive measure is completely monotone on the interior of the set where it is finite, by differentiation under the integral, the derivatives being dominated near each such point by the integrand at a point with smaller coordinates, and it is log-convex along segments by Hölder's inequality. For one cell, with $\lambda = 1/p$ and $p = 1/q$, the measure $e^{-\lambda}\mathfrak{r}_F$ becomes $e^{-q}q^{s-\kappa-1}dq$ against the law, and the coordinate $\mu = pz$ becomes z/q; for $\check{\mathfrak{r}}_F$, with $p = \rho\gamma^\Psi(u)$, the same

computation gives the image of $z^{-\kappa}(\varrho_{\mathcal{A}})_*\phi_{\mathcal{A}}(dz)\otimes p^{\kappa-t-1}dp$ under $(z,p)\mapsto(1/p,p/z)$, and $e^{-\lambda}$ and $p=1/q$ give the image of $z^{-\kappa}(\varrho_{\mathcal{A}})_*\phi_{\mathcal{A}}(dz)\otimes q^{t-\kappa-1}e^{-q}dq$ under $(z,q)\mapsto 1/(zq)$.

(iii) Insert the Laplace form of (ii) and integrate first in x_j, $j\geq 2$, and y_j (Tonelli): $\int_0^\infty x^{a-1}e^{-x\lambda}dx=\Gamma(a)\lambda^{-a}$. With $\lambda_j=1/(pz_{j,K})$, $\mu_j=pz_{j,\Psi}$ and $x_1=1$,

$$\prod_{j\geq 2}\Gamma(a_j)\prod_j\Gamma(b_j)\iint e^{-1/p}\prod_{j\geq 2}(pz_{j,K})^{a_j}\prod_j(pz_{j,\Psi})^{-b_j}\prod_j z_{j,K}^{-s_j}\,p^{\kappa-|\mathbf{s}|-1}dp\,(\boldsymbol{\varrho}_F)_*\phi_F(d\mathbf{z}).$$

The power of p is p^{-a_1-1} with $a_1=\sum_j b_j-\sum_{j\geq 2}a_j-\kappa+|\mathbf{s}|$, the given a_1 by the hyperplane, and $\int_0^\infty e^{-1/p}p^{-a_1-1}dp=\Gamma(a_1)$ for $a_1>0$; the power of $\mathbf{z}$ is $\prod_j z_{j,K}^{-(s_j-a_j)}z_{j,\Psi}^{-b_j}$, $z_{1,K}=1$ (check 5). For $\check{f}_F$ the law form of $\check{\mathfrak{r}}_F$, obtained as in (ii) with $p=\rho\gamma_1^\Psi$, is the image of $z_{1,\Psi}^{-\kappa}\prod_j(z_{j,\Psi}/z_{1,\Psi})^{-t_j}(\boldsymbol{\varrho}_F)_*\phi_F(d\mathbf{z})\otimes p^{\kappa-|\mathbf{t}|-1}dp$ under $(\mathbf{z},p)\mapsto\big((z_{1,\Psi}/(pz_{j,\Psi}))_j,(pz_{j,K}/z_{1,\Psi})_j\big)$; the same integration leaves p^{-a_1-1} with $a_1=\sum_j b_j-\sum_{j\geq 2}a_j-\kappa+|\mathbf{t}|$, and the total power of $z_{1,\Psi}$ is $-\sum_{j\geq 2}a_j+\sum_j b_j-\kappa+\sum_{j\geq 2}t_j=a_1-t_1$, so the power of $\mathbf{z}$ is $\prod_j z_{j,K}^{-b_j}z_{j,\Psi}^{-(t_j-a_j)}$. Both points satisfy $\sum_j(z_{j,K}+z_{j,\Psi})=\kappa$. At $N=1$, $b=z$ and $a=z+s-\kappa$, the first gives $\Gamma(z)\Gamma(z+s-\kappa)\int\varrho_{\mathcal{A}}^{-z}d\phi_{\mathcal{A}}$, and the second, with $a=z+t-\kappa$, $\Gamma(z)\Gamma(z+t-\kappa)\int\varrho_{\mathcal{A}}^{-(\kappa-z)}d\phi_{\mathcal{A}}$.

(iv) Table by table, the dual table $\mathcal{A}^*$ has the bases $(B\sqcup\{g\})\setminus T$ with the weights θ_T, and splitting by whether $g\in T$,

$$K_{\mathcal{A}^*/g}=\Psi_{\mathcal{A}\setminus g},\quad K_{\mathcal{A}^*\setminus g}=\Psi_{\mathcal{A}/g},\quad \Psi_{\mathcal{A}^*\setminus g}=K_{\mathcal{A}/g},\quad \Psi_{\mathcal{A}^*/g}=K_{\mathcal{A}\setminus g},$$

its rank is $|B|+1-r_{\mathcal{A}}$, and g is neither a loop nor a coloop of it. So $\gamma^K_{\mathcal{A}^*}=\gamma^\Psi_{\mathcal{A}}$ and $\gamma^\Psi_{\mathcal{A}^*}=\gamma^K_{\mathcal{A}}$, and the hinge wall at (t_j,s_j) is $m_B-\sum_j\big(t_j(|B|-r_{\mathcal{A}_j})+s_j(r_{\mathcal{A}_j}-1)\big)=\kappa$. The base form of F^* is $u^{\mathbf{m}-\mathbf{1}}\prod_j\Psi_{\mathcal{A}_j\setminus g}^{-t_j}K_{\mathcal{A}_j/g}^{-s_j}(\gamma_1^\Psi)^{-\kappa}=(\gamma_1^\Psi/\gamma_1^K)^{-\kappa}\phi_F$, its ratio vector is $(\gamma_j^\Psi/\gamma_1^\Psi,\gamma_j^K/\gamma_1^\Psi)_j=(z_{j,\Psi}/z_{1,\Psi},z_{j,K}/z_{1,\Psi})_j$ at $\mathbf{z}=\boldsymbol{\varrho}_F$, which gives the law, and the orthant forms of f_{F^*} and $\check{f}_{F^*}$ are those of $\check{f}_F$ and f_F. At $N=1$ the ratio is $1/\varrho_{\mathcal{A}}$, and $\int\varrho_{\mathcal{A}^*}^{-z}d\phi_{\mathcal{A}^*}=\int\varrho_{\mathcal{A}}^{z}\varrho_{\mathcal{A}}^{-\kappa}d\phi_{\mathcal{A}}$.

(v) By (iii) for f_F at $(\mathbf{a},\mathbf{b})$ and for $\check{f}_F$ at $(\mathbf{t}-\mathbf{b},\mathbf{s}-\mathbf{a})$, whose hyperplane condition $\sum_j(s_j-a_j)-\sum_j(t_j-b_j)=\kappa-|\mathbf{t}|$ is that of $(\mathbf{a},\mathbf{b})$, the Mellin transform of the law appears at the same point $(\mathbf{s}-\mathbf{a},\mathbf{b})$ on both sides, with the Gamma products $\prod_j\Gamma(a_j)\Gamma(b_j)$ and $\prod_j\Gamma(t_j-b_j)\Gamma(s_j-a_j)$; all these Gammas are finite and positive, which gives the relation in $(0,\infty]$. At $N=1$, with $z=s-a$ and $b=\kappa-z$, the ratio of the Gammas is that of the displayed one-cell relation (check 6). The expansion clause concerns the node of width one of one table and is the reference's. □

Lemma S10. *Let F be a cell family with plain tables, $s_j,t_j>0$, and $\mathbf{a},\mathbf{b}\in(0,\infty)^N$ real with $\sum_j b_j-\sum_j a_j=\kappa_F-|\mathbf{s}|$ and $\int\boldsymbol{\varrho}_F^{-(\mathbf{s}-\mathbf{a},\mathbf{b})}d\phi_F<\infty$. Write $\mathbf{u}=(x_2,\dots,x_N,y_1,\dots,y_N)\in(0,\infty)^{2N-1}$, $g(\mathbf{u})=f_F((1,x_2,\dots,x_N),\mathbf{y})$, $\mathbf{c}=(a_2,\dots,a_N,b_1,\dots,b_N)$, and for $\boldsymbol{\tau}=(\tau_2,\dots,\tau_N,\tau'_1,\dots,\tau'_N)\in\mathbb{R}^{2N-1}$ put $\tau_1=\sum_j\tau'_j-\sum_{j\geq 2}\tau_j$ and*

$$G(\boldsymbol{\tau})=\prod_j\Gamma(a_j+i\tau_j)\Gamma(b_j+i\tau'_j)\int\boldsymbol{\varrho}_F^{-(\mathbf{s}-\mathbf{a}-i\boldsymbol{\tau}_K,\ \mathbf{b}+i\boldsymbol{\tau}_\Psi)}d\phi_F,$$

$\boldsymbol{\tau}_K=(\tau_j)_j$ and $\boldsymbol{\tau}_\Psi=(\tau'_j)_j$. Then g is finite and continuous on $(0,\infty)^{2N-1}$, G is the Mellin transform of g on the vertical subspace through $\mathbf{c}$ and is integrable, and

$$g(\mathbf{u})=(2\pi)^{1-2N}\int_{\mathbb{R}^{2N-1}}G(\boldsymbol{\tau})\,\mathbf{u}^{-\mathbf{c}-i\boldsymbol{\tau}}\,d\boldsymbol{\tau}\qquad(\mathbf{u}\in(0,\infty)^{2N-1}).$$

Proof. The computation of 23.8(iii) at the complex exponents $\mathbf{c}+i\boldsymbol{\tau}$ converges absolutely, its integrand having at every point the modulus of the integrand at $\mathbf{c}$, so it computes the Mellin transform of g at $\mathbf{c}+i\boldsymbol{\tau}$ as $G(\boldsymbol{\tau})$; the point $(\mathbf{s}-\mathbf{a}-i\boldsymbol{\tau}_K, \mathbf{b}+i\boldsymbol{\tau}_\Psi)$ stays on the hyperplane, which fixes τ_1. By 23.1, $|G(\boldsymbol{\tau})| \le \prod_j |\Gamma(a_j+i\tau_j)\Gamma(b_j+i\tau'_j)| \int \boldsymbol{\varrho}_F^{-(\mathbf{s}-\mathbf{a},\mathbf{b})} d\phi_F$, and the bound $|\Gamma(c+i\tau)| \le C_c\, e^{-\pi|\tau|/2}(1+|\tau|)^{c-1/2}$ makes G integrable on $\mathbb{R}^{2N-1}$. The Mellin transform of g at the real point $\mathbf{c}$ is finite, so $g<\infty$ almost everywhere. By 23.8(ii), g is the Laplace transform of a positive measure in the variables $\mathbf{u}$, hence nonincreasing in each of them: if g were infinite at a point it would be infinite on the set of points below it, which has positive measure. So g is finite everywhere, and continuous by dominated convergence, the integrand near a point being dominated by the integrand at a point with smaller coordinates. In the coordinates $\mathbf{v}=\log\mathbf{u}$ the function $g(e^{\mathbf{v}})e^{\langle \mathbf{c},\mathbf{v}\rangle}$ is integrable with the integrable Fourier transform G, so the Fourier inversion theorem gives the display almost everywhere, and everywhere since both sides are continuous. □

Theorem 23.9 (Two cell families glued). *As stated, for two cell families with plain tables and $s_j, t_j > 0$.*

Proof. (i) 23.6(i) with the core $\binom{\{g_1,g_2\}}{1}$ in every table, F_1 at g_1 and F_2 at g_2, the period of the twisted core family being $\mathcal{G}$.

(ii), first form. The gluing of two cells along the hinge is the series closure $\binom{\{h_1,h_2\}}{1}\langle \mathcal{A}_1, \mathcal{A}_2\rangle$ (21.7(iii)), so 23.3 at $q=2$ gives

$$P = C\int \prod_j x_j^{s_j-1} \prod_{j\ge 2} y_j^{t_j-1}\, f_{F_1} f_{F_2}\big(\mathbf{x},(1,\mathbf{y}')\big)\, d\mathbf{x}\, d\mathbf{y}', \qquad C=\prod_j \frac{1}{\Gamma(s_j)\Gamma(t_j)}.$$

Substitute $\mathbf{x}=x_1(1,\boldsymbol{\xi})$, $d\mathbf{x}=x_1^{N-1}dx_1\, d\boldsymbol{\xi}$, and use the homogeneity of 23.1 with $c=x_1$, $f_{F_i}(\mathbf{x},(1,\mathbf{y}')) = x_1^{\kappa_{F_i}-|\mathbf{s}|} f_{F_i}((1,\boldsymbol{\xi}), x_1(1,\mathbf{y}'))$; then substitute $\boldsymbol{\eta}=x_1(1,\mathbf{y}')$, $dx_1\, d\mathbf{y}' = x_1^{1-N} d\boldsymbol{\eta}$. The powers of $x_1=\eta_1$ collect to

$$(|\mathbf{s}|-N)+(N-1)+(\kappa_{F_1}+\kappa_{F_2}-2|\mathbf{s}|)+(1-N)-(|\mathbf{t}|-t_1)+(N-1) = t_1-1,$$

since $\kappa_{F_1}+\kappa_{F_2}=|\mathbf{s}|+|\mathbf{t}|$ (check 10 of S21-23_work/checks.py): the first form.

(ii), second form. The complements of the bases of a two-sum of cells are the bases of the two-sum of the dual cells: for X a basis of $\mathcal{A}\setminus g$ and $Y\sqcup\{g\}$ one of $\mathcal{A}'$, $B\setminus X$ is a basis of $\mathcal{A}^*/g$ and $R\setminus Y$ one of $\mathcal{A}'^*\setminus g$, and symmetrically (21.2), with the product weights. By 8.15 the period of $F_1\oplus_g F_2$ at $(\mathbf{s},\mathbf{t})$ is that of $F_1^*\oplus_g F_2^*$ at $(\mathbf{t},\mathbf{s})$, and by 23.8(iv) the dual cell families have the hinge walls $\kappa_{F_1},\kappa_{F_2}$ and the transforms $\check{f}_{F_1}, \check{f}_{F_2}$. The first form for them is the second form.

(iii) Insert the Laplace forms of 23.8(ii) into (ii) and integrate first in x_j, $j\ge 2$, and y_j (Tonelli): $\int_0^\infty x^{s-1}e^{-x(\lambda+\lambda')}dx = \Gamma(s)(\lambda+\lambda')^{-s}$, and $x_1=1$ leaves $e^{-\lambda_1-\lambda'_1}$; the factors $\Gamma(s_j)$, $j\ge 2$, and $\Gamma(t_j)$ cancel against C. The period converges exactly when every proper wall is positive (8.7).

(iv) Let the contour have the real point $(\mathbf{a}^d,\mathbf{b}^d,\mathbf{a}^r,\mathbf{b}^r)$, all coordinates positive, with $\mathbf{a}^d+\mathbf{a}^r=\mathbf{s}$, $\mathbf{b}^d+\mathbf{b}^r=\mathbf{t}$ and $\sum_j(a_j^r+b_j^d)=\kappa_{F_1}$, and put $\mathbf{a}=\mathbf{a}^d$, $\mathbf{b}=\mathbf{b}^d$; then $\sum_j b_j-\sum_j a_j = \kappa_{F_1}-|\mathbf{s}|$, and the Mellin transform of the law of F_1 at $(\mathbf{s}-\mathbf{a},\mathbf{b})=(\mathbf{a}^r,\mathbf{b}^d)$ is finite. By Lemma S10, f_{F_1} is the inverse Mellin integral of G_1 through $\mathbf{c}$. Insert it into the first form of (ii). The double integral converges absolutely: integrating first in $\mathbf{u}$ gives $\int |G_1|\, d\boldsymbol{\tau}$ times $\int \prod_{j\ge2} x_j^{s_j-a_j-1}\prod_j y_j^{t_j-b_j-1} f_{F_2}\, d\mathbf{x}'\, d\mathbf{y}$, which is 23.8(iii) for F_2 at $(\mathbf{s}-\mathbf{a},\mathbf{t}-\mathbf{b})$: its first coordinate is $|\mathbf{t}|-|\mathbf{b}|-(|\mathbf{s}|-s_1-\sum_{j\ge2}a_j)-\kappa_{F_2}+|\mathbf{s}| = s_1-a_1$, by $\kappa_{F_2}=2\sigma-\kappa_{F_1}$, so it equals $\prod_j\Gamma(s_j-a_j)\Gamma(t_j-b_j)\int \boldsymbol{\varrho}_{F_2}^{-(\mathbf{a}^d,\mathbf{b}^r)}d\phi_{F_2}<\infty$. By Fubini,

$$P = C\,(2\pi)^{1-2N}\int_{\mathbb{R}^{2N-1}} \prod_j \Gamma(a_j^d)\Gamma(b_j^d)\Gamma(a_j^r)\Gamma(b_j^r) \int \boldsymbol{\varrho}_{F_1}^{-(\mathbf{a}^r,\mathbf{b}^d)}d\phi_{F_1}\int \boldsymbol{\varrho}_{F_2}^{-(\mathbf{a}^d,\mathbf{b}^r)}d\phi_{F_2}\, d\boldsymbol{\tau},$$

the shares moving with the imaginary parts $\boldsymbol{\tau}$ of $(a_2^d,\dots,a_N^d,b_1^d,\dots,b_N^d)$, the others fixed by the pins, and $C\prod_j\Gamma(\cdot)$ is $\prod_j\Gamma_{\,2}^{\,4}\left[\begin{matrix}a_j^d,\ b_j^d,\ a_j^r,\ b_j^r\\ s_j,\ t_j\end{matrix}\right]$. This is the fibre integral of 4.1 over the level shares with their $2N+1$ pins: solved for a_j^r, b_j^r and a_1^d the matrix of the pins has $|\det|=1$, so the fibre integral is $(2\pi)^{1-2N}$ times the integral over $\boldsymbol{\tau}$. In the pair coordinates of 19.13, $\sigma_j^d=\frac12(a_j^d+b_j^d)$ and $\delta_j^d=\frac12(a_j^d-b_j^d)$ with the one pin $\sum_j\delta_j^d=\frac12(|\mathbf{s}|-\kappa_{F_1})$, the linear map from $\boldsymbol{\tau}$ to the imaginary parts of $(\sigma_1^d,\dots,\sigma_N^d,\delta_2^d,\dots,\delta_N^d)$ has $|\det|=2^{1-N}$: the map $(a,b)\mapsto(\frac{a+b}{2},\frac{a-b}{2})$ of $\mathbb{R}^{2N}$ has $|\det|=2^{-N}$, it sends the normal coordinate $\sum_j(a_j-b_j)$ of the pin to twice the normal coordinate $\sum_j\delta_j$, and the quotient is 2^{1-N}. So the integral is 2^{N-1} times the fibre integral in the pair coordinates, the formula of 19.13. That the two Mellin transforms are the periods of the bunch family and of the room family at the level shares is the identity $u^{\mathbf{m}-\mathbf{1}}\prod_j K_{\mathcal{A}_j/g}^{-a_j^d}\Psi_{\mathcal{A}_j/g}^{-b_j^d}K_{\mathcal{A}_j\setminus g}^{-a_j^r}\Psi_{\mathcal{A}_j\setminus g}^{-b_j^r}=\boldsymbol{\varrho}_{F_1}^{-(\mathbf{a}^r,\mathbf{b}^d)}(\gamma_{\mathcal{A}_1}^K)^{\kappa_{F_1}-\sum_j(a_j^r+b_j^d)}$ times the density of ϕ_{F_1}, the last power being 1 on the pin, with $\mathcal{B}_j|B=\mathcal{A}_j\setminus g$ and $\mathcal{B}_j/R=\mathcal{A}_j/g$ (21.12), and its analogue for the room, whose pin $\sum_j(a_j^d+b_j^r)=2\sigma-\kappa_{F_1}=\kappa_{F_2}$ follows from the letter totals.

One table. At $N=1$ the laws are measures on $(0,\infty)$, the kernel is that of 23.7, (ii) and (iii) have no variables x_j, the image of $e^{-\lambda}\mathfrak{r}_{F_i}$ under μ being $\mathfrak{r}^\Psi$, and in (iv) the fibre is the line of $b^d=z$, with $a^d=s-\kappa_{\mathcal{A}}+z$, $a^r=\kappa_{\mathcal{A}}-z$, $b^r=t-z$; the conditions on the contour are $\max(0,\kappa_{\mathcal{A}}-s)<z_0<\min(t,\kappa_{\mathcal{A}})$ and the finiteness of $\int\varrho_{\mathcal{A}}^{-z_0}d\phi_{\mathcal{A}}$ and $\int\varrho_{\mathcal{A}'}^{z_0-t}d\phi_{\mathcal{A}'}$, and $d\sigma^d=dz$. The first form of (ii) is 20.26(i) with the room transform $y^tf_{\mathcal{A}'}(y)$. □

Definition 23.10 (One weighted mark). As stated: the one-mark cell family of a ratio vector, with two systems of weights in every table.

Proof. Table j has the bases $\{e\}$ and $\{g\}$, with $\theta^K=(x_{0,j,K},1)$ and $\theta^\Psi=(1,x_{0,j,\Psi})$, so $K_j=x_{0,j,K}\alpha_e+\alpha_g$ and $\Psi_j=\theta^\Psi_{\{e\}}\alpha_g+\theta^\Psi_{\{g\}}\alpha_e=\alpha_g+x_{0,j,\Psi}\alpha_e$, two systems of weights being allowed (21.1, 8.1). The hinge minors are $K_{\setminus g}=x_{0,j,K}\alpha_e$, $K_{/g}=1$, $\Psi_{\setminus g}=1$ and $\Psi_{/g}=x_{0,j,\Psi}\alpha_e$, so the hinge values are $x_{0,j,K}\alpha_e$ and $x_{0,j,\Psi}\alpha_e$ and the ratio vector is the constant $\mathbf{x}_0$, $x_{0,1,K}=1$. The rank is 1 and $|B|=1$, so the hinge wall is m_e. The simplex $\Delta_{\{e\}}$ is the point $u_e=1$, carrying the unit mass, and there the density of the base form is $1\cdot1\cdot(x_{0,1,K})^{-m_e}=1$: the law is $\delta_{\mathbf{x}_0}$. □

Theorem 23.11 (The law is what a cell family retains). *As stated, for every pair of cell families with plain tables and $s_j,t_j>0$.*

Proof. (a)⇒(b). By 23.6(i) with the core $\binom{\{g_1,g_2\}}{1}$, the period of $F\oplus_gF''$ depends on F only through κ and its law; this needs no plainness of F''. (b)⇒(c) is a special case.

(c)⇒(d). By 23.6(i) and the law $\delta_{\mathbf{x}_0}$ of the one-mark cell family (23.10), the period against it is $\Pi_F(\mathbf{x}_0)=\int\mathcal{G}(\mathbf{z},\mathbf{x}_0)\,d((\boldsymbol{\varrho}_F)_*\phi_F)(\mathbf{z})$, $\mathcal{G}(\mathbf{z},\mathbf{x}_0)=\int_0^\infty v^{\kappa-1}\prod_j(z_{j,K}v+x_{0,j,K})^{-s_j}(z_{j,\Psi}v+x_{0,j,\Psi})^{-t_j}dv$. Since $(zv+x)/(zv+x')$ lies between $\min(1,x/x')$ and $\max(1,x/x')$, $\mathcal{G}(\cdot,\mathbf{x}_0)$ and $\mathcal{G}(\cdot,\mathbf{x}_0')$ are comparable within constants that depend on $\mathbf{x}_0,\mathbf{x}_0'$ only, so Π_F is finite everywhere on $(0,\infty)^{2N-1}$ or nowhere.

Take the Mellin transform of Π_F in the coordinates of $\mathbf{x}_0$ other than $x_{0,1,K}=1$, with the exponents $s_j-z_{j,K}$ at $x_{0,j,K}$, $j\ge2$, and $t_j-z_{j,\Psi}$ at $x_{0,j,\Psi}$. By Tonelli and $\int_0^\infty q^{w-1}(c+q)^{-s}dq=c^{w-s}\Gamma_{\,2}^{\,2}\left[\begin{matrix}w,\ s-w\\ s\end{matrix}\right]$, $0<w<s$, each coordinate gives a Beta corner and the power $(z_{j,K}v)^{-z_{j,K}}$ or $(z_{j,\Psi}v)^{-z_{j,\Psi}}$, and the remaining integral is $\int_0^\infty v^{z_{1,K}-1}(1+v)^{-s_1}dv=\Gamma_{\,2}^{\,2}\left[\begin{matrix}z_{1,K},\ s_1-z_{1,K}\\ s_1\end{matrix}\right]$, the

power of v collecting to $v^{z_{1,K}-1}$ by the hyperplane. So the Mellin transform is

$$\prod_{j\geq 2}\Gamma_2^1\begin{bmatrix}s_j-z_{j,K},\ z_{j,K}\\ s_j\end{bmatrix}\,\Gamma_2^1\begin{bmatrix}z_{1,K},\ s_1-z_{1,K}\\ s_1\end{bmatrix}\prod_j\Gamma_2^1\begin{bmatrix}t_j-z_{j,\Psi},\ z_{j,\Psi}\\ t_j\end{bmatrix}\int \boldsymbol{\varrho}_F^{-\mathbf{z}}\,d\phi_F<\infty.$$

In particular Π_F is finite almost everywhere, hence everywhere. For complex exponents with these real parts the same computation converges absolutely, and the Beta corners at complex arguments of positive real part do not vanish. Where finite, Π_F extends holomorphically to the product of right half-planes: $|(zv+\zeta)^{-s}|\leq(zv+\operatorname{Re}\zeta)^{-s}$ for $\operatorname{Re}\zeta>0$ and $s>0$, so dominated convergence and Morera's theorem give holomorphy in each coordinate, the extension being locally bounded, and hence jointly. So Π_F and $\Pi_{F'}$ are real-analytic on $(0,\infty)^{2N-1}$, equal on a nonempty open set, and equal everywhere; their Mellin transforms on the vertical subspace through $\mathbf{z}$ agree, which is (d).

(d)⇒(a). The finite measures $\boldsymbol{\varrho}^{-\mathbf{z}}(\boldsymbol{\varrho}_F)_*\phi_F$ and $\boldsymbol{\varrho}^{-\mathbf{z}}(\boldsymbol{\varrho}_{F'})_*\phi_{F'}$ on $(0,\infty)^{2N-1}$, read in the logarithms of the coordinates, have the Fourier transforms $\boldsymbol{\tau}\mapsto\int\boldsymbol{\varrho}^{-(\mathbf{z}+i\boldsymbol{\tau})}d\phi$, equal by (d); a finite measure on $\mathbb{R}^{2N-1}$ is determined by its Fourier transform, so the two measures agree, and multiplying by the positive continuous function $\boldsymbol{\varrho}^{\mathbf{z}}$ the laws agree. This replaces the Gaussian smoothing of the reference proof of 23.11, which is the same argument on the line.

One table. The plain one-mark cell of ratio x_0 has the law $x_0^{(m_e-s)/2}\delta_{x_0}$, a positive multiple of the point law, and its ratios fill $(0,\infty)$, so (c) with the plain cells gives the equality of Π_F on an open interval; (d) is the case $N=1$, $\mathbf{w}=(w_{1,K},w)$ with $w_{1,K}$ not entering. □

Corollary 23.12 (Cells that are marks). *As stated: (i) for every cell family with plain tables and $s_j,t_j>0$.*

Proof. (i) This is the reference proof of 23.12(i) with the ratio vector in place of the ratio. If $\boldsymbol{\varrho}_F\equiv\mathbf{x}_0$, the image of ϕ_F is $\phi_F(\Delta_B)\delta_{\mathbf{x}_0}$. Conversely, ϕ_F has a positive continuous density on the open simplex and $\boldsymbol{\varrho}_F$ is continuous, so if the law is carried by $\mathbf{x}_0$ the open set $\{\boldsymbol{\varrho}_F\neq\mathbf{x}_0\}$ has ϕ_F-measure 0 and is empty. The mass $\phi_F(\Delta_B)$ is positive. By 23.6(i), the period of a gluing $F\oplus_g F''$ is $\phi_F(\Delta_B)\int\mathcal{G}(\mathbf{x}_0,\mathbf{z}')\,d((\boldsymbol{\varrho}_{F''})_*\phi_{F''})(\mathbf{z}')$, a positive multiple of $\phi_F(\Delta_B)$; so a finite period forces $\phi_F(\Delta_B)<\infty$, and the integral is the period of the gluing of the one-mark cell family of ratio vector $\mathbf{x}_0$ and mass κ_F with F'', whose law is $\delta_{\mathbf{x}_0}$ and whose hinge wall is κ_F. For one plain cell, the one-mark cell of ratio x_0 and mass $\kappa_{\mathcal{A}}$ has the law $x_0^{(\kappa_{\mathcal{A}}-s)/2}\delta_{x_0}$, which gives the factor. (ii) and (iii) are the reference's. □

Theorem 23.14 (Series and parallel nodes). *As stated: (i) and (ii) for cell families with plain tables and $s_j,t_j>0$.*

Proof. This is the reference proof of 23.14(i),(ii), table by table. *(i)* The series core $\binom{G}{q}$, $G=\{g_0,\dots,g_q\}$, has rank q; its deletion at g_0 has the one basis $\{g_1,\dots,g_q\}$, so $K_{\binom{G}{q}\setminus g_0}(\mathbf{v})=\prod_i v_i$ and $\Psi_{\binom{G}{q}\setminus g_0}=1$, and its contraction has the bases of size $q-1$ of $\{g_1,\dots,g_q\}$, so $K_{\binom{G}{q}/g_0}=e_{q-1}(\mathbf{v})$ and $\Psi_{\binom{G}{q}/g_0}(\mathbf{v})=\sum_i v_i$. By 23.5,

$$K_{\mathcal{A}_j\setminus g_0}=\prod_i K_{\mathcal{A}_{ij}/g_i}\gamma^K_{\mathcal{A}_{ij}}=\prod_i K_{\mathcal{A}_{ij}\setminus g_i},\qquad \Psi_{\mathcal{A}_j\setminus g_0}=\prod_i\Psi_{\mathcal{A}_{ij}\setminus g_i},$$

and the hinge values of $\mathcal{A}_j$ are $\prod_i\gamma^K_{\mathcal{A}_{ij}}/e_{q-1}((\gamma^K_{\mathcal{A}_{ij}})_i)$, whose reciprocal is $\sum_i 1/\gamma^K_{\mathcal{A}_{ij}}$, and $\sum_i\gamma^\Psi_{\mathcal{A}_{ij}}$. In the orthant form of f_F the measure $\alpha^{\mathbf{m-1}}\prod_j K_{\mathcal{A}_j\setminus g_0}^{-s_j}\Psi_{\mathcal{A}_j\setminus g_0}^{-t_j}d\alpha$ is the product over i of the

measures of the cell families, and the exponential is the product of their exponentials, so Tonelli gives $f_F = \prod_i f_{F_i}$, and the image of the product measure under the sum of the maps of the factors is the convolution: $\mathfrak{r}_F = *_i \mathfrak{r}_{F_i}$. The hinge-wall formula of 23.6(ii), with $\mathcal{E}_{\mathcal{H}} = \varnothing$, $k = q$ and $r_{\mathcal{H}_j} = q$, gives $\kappa_F = \sum_i \kappa_{F_i} - (q-1)|\mathbf{s}|$ (check 3a of S21-23_work/checks.py). For one table, $f_{\mathcal{A}}(y) = f_F(1, y) = \prod_i f_{F_i}(1, y)$, and since $e^{-\lambda} = \prod_i e^{-\lambda_i}$ for $\lambda = \sum_i \lambda_i$, the measure $e^{-\lambda}\mathfrak{r}_F$ is the convolution of the $e^{-\lambda_i}\mathfrak{r}_{F_i}$, whose images under μ convolve: $\mathfrak{r}^{\Psi}_{\mathcal{A}} = *_i \mathfrak{r}^{\Psi}_{\mathcal{A}_i}$. The twisted series core is the reference's.

(ii) The parallel core $\binom{G}{1}$ has rank 1: $K_{\binom{G}{1}\backslash g_0} = \sum_i v_i$, $K_{\binom{G}{1}/g_0} = 1$, $\Psi_{\binom{G}{1}\backslash g_0} = e_{q-1}(\mathbf{v})$ and $\Psi_{\binom{G}{1}/g_0} = \prod_i v_i$. So $K_{\mathcal{A}_j/g_0} = \prod_i K_{\mathcal{A}_{ij}/g_i}$, $\Psi_{\mathcal{A}_j/g_0} = \prod_i \Psi_{\mathcal{A}_{ij}\backslash g_i} \gamma^{\Psi}_{\mathcal{A}_{ij}} = \prod_i \Psi_{\mathcal{A}_{ij}/g_i}$, the hinge values combine as stated, the orthant form of $\check{f}_F$ factors, and $\kappa_F = \sum_i \kappa_{F_i} - (q-1)|\mathbf{t}|$ (check 3b). Equally, 23.8(iv) exchanges (i) and (ii) through the dual cell families, the dual of a parallel core being a series core. (iii) and (iv) are the reference's. □

Definition 23.15 (Hinge tree). As stated: the common hinge tree of the tables of a family, with its node families and its cell families.

Remark. The added objects are definitions. Each $\mathcal{A}_{v,j}$ is a cell with the hinge $g_{v,\mathfrak{e}_v}$ on the marks below v (23.15), the same for every j, so the $\mathcal{A}_{v,j}$ form a cell family in the sense of 23.1; and the substitution along the tree does not depend on the order of the two-sums, table by table (23.5).

Theorem 23.17 (The period along a hinge tree). *As stated: for every family whose tables have a common hinge tree, at real data.*

Proof. Induction from the leaves. At a leaf v the cell family F_v is the node family with its one marker as hinge. At an inner vertex $v \neq o$, table j of F_v is the substitution of the node $\mathcal{H}_{v,j}$, a hinged core with the hinge $g_{v,\mathfrak{e}_v}$, with the subtree cells $\mathcal{A}_{w,j}$ of the vertices w directly below it at the markers of their edges (23.15), so 23.6(ii) gives (i), the masses on $\mathcal{E}_v$ being those of F. At the root, the node has no hinge, and 23.6(i) gives (ii). (iii) is the recursion of (i): the law at v is computed from the nodes and masses at v and the laws of the vertices directly below, and by induction from the data below v. This is the reference proof of 23.17 (thm:contraction), with 23.6 for families, which the reference's remark on families (rem:familiesnodes) gives verbatim. □

Proposition 23.18 (What the work depends on). *As stated, for a family whose tables have a common hinge tree.*

Proof. (i) A bijection of marks carrying the subtree cells onto each other in every table, with their weights, masses and hinge, carries the letters onto the letters, hence the base forms and the ratio vectors onto each other; the ranks, sizes and masses are kept, and so is the hinge wall.

(ii) At a series node of unit weights, F_v is the series connection of the cell families directly below (23.13), so 23.14(i) gives $f_{F_v} = \prod_w f_{F_w}$ and $\kappa_{F_v} = \sum_w \kappa_{F_w} - (q-1)|\mathbf{s}|$, $q = \sum_l k_l$; members of one orbit have equal transforms and hinge walls by (i), and collecting them gives the powers. A weight θ_{g_i} on the basis of a series node that omits the marker g_i is carried, by the weight formula of 21.1, by the cell at g_i as the factor $\theta_{g_i}/\theta_{g_0}$ on its bases through its hinge, the weight θ_{g_0} of the basis omitting the hinge remaining as a constant factor of the table; so a series node with weights is a series connection of cells so weighted, and the orbits are taken of these. The parallel node is the same with 23.14(ii).

(iii) By 23.1 the hinge wall of F_v is $m_{B_v} - \sum_j \big(s_j(r_{\mathcal{A}_{v,j}} - 1) + t_j(|B_v| - r_{\mathcal{A}_{v,j}})\big)$, B_v the marks below v, and by 23.5 the ranks $r_{\mathcal{A}_{v,j}}$ are sums of the ranks of the nodes below v less one per edge. A change at v_0 keeping the total mass at v_0, the ranks and the numbers of marks of the nodes,

keeps every m_{B_v}, rank and size, since B_v contains all of $\mathcal{E}_{v_0}$ or none of it; so no hinge wall changes, and by 23.17(iii) the law of F_v changes only if v_0 lies below v, that is, for v on the path from v_0 to the root. A change of masses at v_0 and v_1 keeping the total changes m_{B_v} exactly when B_v contains one of $\mathcal{E}_{v_0}, \mathcal{E}_{v_1}$ and not the other, by the change of the total mass below $\mathfrak{e}_v$. □

Definition 23.19 (The hinge tree procedure). As stated: for a family whose tables have a common hinge tree, the representations (a) and (b) in $2N-1$ variables, (c) for one table.

Remark. Each operation rests on a statement for families. The laws and hinge walls of the orbits are those of 23.17 and 23.18(i). (1) The one-mark leaf: by 23.8(i) at the point law $\delta_{\mathbf{x}_0}$ with $\kappa = m_e$, $f(\mathbf{x},\mathbf{y}) = \prod_j x_{0,j,K}^{-s_j} \mathsf{G}_{|\mathbf{s}|-m_e;(1,-1)}(\sum_j x_j/x_{0,j,K}, \sum_j y_j x_{0,j,\Psi})$, and the second law form with torus homogeneity at $\lambda = x_{0,1,\Psi}$ gives $\check{f}(\mathbf{x},\mathbf{y}) = \prod_j x_{0,j,\Psi}^{-t_j} \mathsf{G}_{|\mathbf{t}|-m_e;(1,-1)}(\sum_j x_j/x_{0,j,\Psi}, \sum_j y_j x_{0,j,K})$, the powers of $x_{0,1,\Psi}$ cancelling; the orthant forms give the same directly. For one table, $\mathbf{x}_0 = (1, x_0)$ and the plain cell's law $x_0^{(m_e-s)/2}\delta_{x_0}$ give the displayed one-table transforms, with $\mathsf{G}_{t-m_e;(1,-1)}(x_0^{-1}, y) = x_0^{t-m_e}\mathsf{G}_{t-m_e;(1,-1)}(1, y/x_0)$. (2) 23.14(i),(ii), with 23.18(ii) for the weights; a pointwise product of transforms is a Mellin convolution of their Mellin transforms of 23.8(iii). (3) 23.8(v) on the Mellin side, and Lemma S10 for the inverse Mellin transform, applied to the dual cell family for $\check{f}$ (23.8(iv)). (4) 23.6(ii) for families. (5) 23.6(i), and for a series or parallel root 23.9(ii) with the series or parallel connection of all but one cell family on one side.

Corollary 23.20 (Series-parallel families). *As stated, for a family whose tables have a common hinge tree of series and parallel nodes over one-mark cell families.*

Proof. This is the reference proof of 23.20 with the family statements. The leaves have their transforms in closed form, Grammas of the marks (the remark after 23.19 in this part). At a series node the transform of the subtree is the product of those below, and at a parallel node the dual transform (23.14), so no integral is taken there; repeated subtrees enter as powers (23.18(ii)). At an edge joining a series node to a parallel node the transform of the subtree below is changed into its dual transform by 23.8(v): the Mellin transform of f on a vertical subspace through a real point $(\mathbf{a},\mathbf{b})$, $0 < a_j < s_j$, $0 < b_j < t_j$, of its domain, an integral on $(0,\infty)^{2N-1}$; multiplication by the ratio of Gammas; and the inverse Mellin transform of the result, which is the Mellin transform of $\check{f}$ (23.8(iii) at $(\mathbf{t}-\mathbf{b}, \mathbf{s}-\mathbf{a})$), an integral on $(0,\infty)^{2N-1}$ that converges absolutely and returns $\check{f}$ by Lemma S10 applied to the dual cell family (23.8(iv)). The hypothesis is the finiteness of the Mellin transform of the law at $\mathbf{z} = (\mathbf{s}-\mathbf{a}, \mathbf{b})$, which these points require. At the root one integral on $(0,\infty)^{2N-1}$ remains, 23.9(ii). The count of the integrations depends only on the edges where the kind of node changes and on the root. For one table the variables are one. □

50.24 Chapter 24: repetition and the change of query

Theorem 24.1 (How often a cell family repeats). *As stated: for every cell family with plain tables, at real exponents.*

Proof. (i) The series connection of k copies of $\mathcal{A}_j$ has $k|B|$ marks besides the hinge, the masses repeated, and the rank $k + k(r_{\mathcal{A}_j} - 1) = kr_{\mathcal{A}_j}$ (23.5, the series core of rank k). By 23.1, since $s_j(kr_{\mathcal{A}_j} - 1) = ks_j(r_{\mathcal{A}_j} - 1) + (k-1)s_j$ and $t_j(k|B| - kr_{\mathcal{A}_j}) = kt_j(|B| - r_{\mathcal{A}_j})$,

$$\kappa_{F_k^{\mathrm{s}}} = km_B - \sum_j \big(s_j(kr_{\mathcal{A}_j} - 1) + t_j(k|B| - kr_{\mathcal{A}_j})\big) = k\kappa_F - (k-1)|\mathbf{s}| = |\mathbf{s}| + k(\kappa_F - |\mathbf{s}|).$$

The parallel connection has the rank $1 + k(r_{\mathcal{A}_j} - 1)$, and the same count gives $k\kappa_F - (k-1)|\mathbf{t}|$ (checks 3a and 3b of S21-23_work/checks.py, which are this count at the exponents as symbols). No sign of an exponent enters.

(ii) The walls of $F_k^{\mathrm{s}} \oplus_g F'$ at the marks of the copies and at those of F' are the hinge walls $\kappa_{F_k^{\mathrm{s}}}$ and $\kappa_{F'}$, and on the balance wall they add to 2σ (21.12). A convergent period has every proper wall positive (8.7, at any complex exponents), so $0 < \kappa_{F_k^{\mathrm{s}}} < 2\sigma$. If $\kappa_F \neq |\mathbf{s}|$ the middle term is unbounded in k, which bounds k: $|\mathbf{s}| - k(|\mathbf{s}| - \kappa_F) > 0$ gives $k < |\mathbf{s}|/(|\mathbf{s}| - \kappa_F)$ when $\kappa_F < |\mathbf{s}|$, and $|\mathbf{s}| + k(\kappa_F - |\mathbf{s}|) < |\mathbf{s}| + |\mathbf{t}|$ gives $k < |\mathbf{t}|/(\kappa_F - |\mathbf{s}|)$ when $\kappa_F > |\mathbf{s}|$. The parallel case is the same with the roles of $|\mathbf{s}|$ and $|\mathbf{t}|$ exchanged. □

Theorem 24.2 (Series repetition). *As stated: (i) for cell families with plain tables and $s_j, t_j > 0$; (ii) to (iv) are the reference's, for one cell.*

Proof. (i) By 23.14(i) with k copies of F, $f_{F_k^{\mathrm{s}}} = f_F^k$; by 24.1(i), $\kappa_{F_k^{\mathrm{s}}} = |\mathbf{s}|$, which lies in $(0, 2\sigma)$ since $|\mathbf{s}|, |\mathbf{t}| > 0$. So the first form of 23.9(ii) applies to F_k^{s} and F' and gives the display. With ν the measure of the statement, $P(k) = \int f_F^k \, d\nu = \int w^k \, d((f_F)_*\nu)(w)$. Where finite, $P(k)^2 = \big(\int f_F^{(k-1)/2} f_F^{(k+1)/2} d\nu\big)^2 \leq P(k-1)P(k+1)$ by the Cauchy–Schwarz inequality, and for $z \geq 0$ Tonelli gives $\sum_k P(k) z^k/k! = \int e^{z f_F} d\nu$.

The value $P(0)$. Insert the orthant form of $f_{F'}$ and integrate first in x_j, $j \geq 2$, and y_j (Tonelli): $\int_0^\infty x^{s_j - 1} e^{-x/\gamma^K} dx = \Gamma(s_j)(\gamma^K)^{s_j}$ and $\int_0^\infty y^{t_j - 1} e^{-y\gamma^\Psi} dy = \Gamma(t_j)(\gamma^\Psi)^{-t_j}$. Since $K_{\mathcal{A}'_j \backslash g}(\gamma^K_{\mathcal{A}'_j})^{-1} = K_{\mathcal{A}'_j/g}$ and $\Psi_{\mathcal{A}'_j \backslash g} \gamma^\Psi_{\mathcal{A}'_j} = \Psi_{\mathcal{A}'_j/g}$, what remains is

$$\prod_{j \geq 2} \Gamma(s_j) \prod_j \Gamma(t_j) \int \alpha^{\mathbf{m}|_R - \mathbf{1}} e^{-1/\gamma^K_{\mathcal{A}'_1}} K_{\mathcal{A}'_1 \backslash g}^{-s_1} \prod_{j \geq 2} K_{\mathcal{A}'_j/g}^{-s_j} \prod_j \Psi_{\mathcal{A}'_j/g}^{-t_j} \, d\alpha.$$

In $\alpha = \rho u$ the power of ρ is $\rho^{\kappa_{F'} - |\mathbf{t}| - s_1 - 1} = \rho^{-s_1 - 1}$, by $\kappa_{F'} = |\mathbf{t}|$ (check 9 of S21-23_work/checks.py), and $\int_0^\infty \rho^{-s_1 - 1} e^{-1/(\rho\gamma)} d\rho = \Gamma(s_1)\gamma^{s_1}$ turns $K_{\mathcal{A}'_1 \backslash g}^{-s_1}$ into $K_{\mathcal{A}'_1/g}^{-s_1}$. So $P(0)$ is the period at $\mathbf{m}|_R$ of the family of the contractions, whose degree is $\sum_j (s_j(r_{\mathcal{A}'_j} - 1) + t_j(|R| - r_{\mathcal{A}'_j} + 1))$, so that it is balanced exactly when $\kappa_{F'} = |\mathbf{t}|$. For one cell, $\int \varrho_{\mathcal{A}'}^{-t} d\phi_{\mathcal{A}'}$ with $\kappa_{\mathcal{A}'} = t$ has the density $u^{\mathbf{m}-\mathbf{1}} K_{\mathcal{A}'/g}^{t-s} K_{\mathcal{A}' \backslash g}^{-t} \Psi_{\mathcal{A}' \backslash g}^{-t} (\gamma^\Psi/\gamma^K)^{-t} = u^{\mathbf{m}-\mathbf{1}} K_{\mathcal{A}'/g}^{-s} \Psi_{\mathcal{A}'/g}^{-t}$, the same period.

(ii) to (iv) are the reference's, for one cell. □

Remark. For a family the asymptotics of $P(k)$ is a Laplace problem in $2N - 1$ variables: a series-balanced cell family has $f_F = \int \mathsf{G}_{0;(1,-1)}(1, ab) \, d\phi_{F \backslash g}$ by 23.3, of the order of $P_{F \backslash g}$ times the logarithm of the scale of $\mathbf{y}$ plus a term that depends on the direction of $\mathbf{y}$ and on $\mathbf{x}'$, and the uniformity of the error in these directions does not follow from the one-variable argument. So (ii) to (iv) are stated for one cell.

Corollary 24.3 (Parallel repetition). *As stated: the first display for cell families with plain tables and $s_j, t_j > 0$; the rest is the reference's, for one cell.*

Proof. By 23.14(ii), $\check{f}_{F_k^{\mathrm{p}}} = \check{f}_F^k$, and by 24.1(i), $\kappa_{F_k^{\mathrm{p}}} = |\mathbf{t}| \in (0, 2\sigma)$; the second form of 23.9(ii) gives the display. For $P(0)$, integrate the orthant form of $\check{f}_{F'}$ in x_j, $j \geq 2$, and y_j: $\int x^{t_j - 1} e^{-x/\gamma^\Psi} dx = \Gamma(t_j)(\gamma^\Psi)^{t_j}$ and $\int y^{s_j - 1} e^{-y\gamma^K} dy = \Gamma(s_j)(\gamma^K)^{-s_j}$ turn $\Psi_{\mathcal{A}'_j/g}^{-t_j}$ into $\Psi_{\mathcal{A}'_j \backslash g}^{-t_j}$, $j \geq 2$, and every $K_{\mathcal{A}'_j/g}^{-s_j}$ into $K_{\mathcal{A}'_j \backslash g}^{-s_j}$; in $\alpha = \rho u$ the power of ρ is $\rho^{\kappa_{F'} - |\mathbf{s}| - t_1 - 1} = \rho^{-t_1 - 1}$, by $\kappa_{F'} = |\mathbf{s}|$, and $\int \rho^{-t_1 - 1} e^{-1/(\rho\gamma_1^\Psi)} d\rho = \Gamma(t_1)(\gamma_1^\Psi)^{t_1}$ turns $\Psi_{\mathcal{A}'_1/g}^{-t_1}$ into $\Psi_{\mathcal{A}'_1 \backslash g}^{-t_1}$. What remains is the period of the family of the deletions at $\mathbf{m}|_R$, balanced exactly when $\kappa_{F'} = |\mathbf{s}|$. Equally, the dual cell families at

$(\mathbf{t},\mathbf{s})$ turn the statement into (i) of 24.2 (23.8(iv), 8.15), the dual of the contractions being the deletions of the duals. The rest is the reference's, for one cell. □

Proposition 24.4 (A chain is a power of one operator). *As stated, for chain cell families at real exponents, (iv) with plain tables and $s_j, t_j > 0$.*

Proof. This is the reference proof of 24.4 with the laws on $(0,\infty)^{2N-1}$. *(i)* 23.6(ii) with the one cell family F_l at g_{in}: its hinge-wall formula, $\mathcal{U}_j$ having the marks $\mathcal{E}_{\mathcal{U}} \sqcup \{g_{\text{in}}\}$ besides its hinge, is $\kappa_{F_{l+1}} = \kappa_{F_l} + \kappa_U$. By 21.12, $F_l \oplus_g F'$ is on its balance wall exactly when $\kappa_{F_l} + \kappa_{F'} = 2\sigma$; with $\kappa_{F_l} = \kappa_{F_0} + l\kappa_U$ this holds for every l exactly when it holds at $l = 0$ and $\kappa_U = 0$.

(ii) 23.6(ii) with the one cell family F_l at g_{in} gives $\lambda_{l+1} = \int \lambda_{\mathbf{x}}^U \, d\lambda_l(\mathbf{x}) = \mathcal{Q}\lambda_l$, the twisted family carrying the mass $\kappa_{F_l} = \kappa_{F_0}$ at g_{in}; by induction $\lambda_l = \mathcal{Q}^l\lambda_0$. 23.6(i) with the core $\binom{\{g_1,g_2\}}{1}$ gives $P_{F_l\oplus_g F'} = \int h_{F'}\, d\lambda_l$, and $\int H\, d(\mathcal{Q}\mu) = \int (\mathcal{Q}^*H)\, d\mu$ for $H \geq 0$ by Tonelli, so $\int h_{F'}\, d\lambda_l = \int (\mathcal{Q}^{*l} h_{F'})\, d\lambda_0$. The series in $z \geq 0$ is summed under the integral by Tonelli.

(iii) $\mathcal{Q}^*$ preserves inequalities between nonnegative functions, so $\mathcal{Q}^*H \leq MH$ gives $\mathcal{Q}^{*l}H \leq M^lH$, and $h_{F'} \leq CH$ gives $\mathcal{Q}^{*l}h_{F'} \leq CM^lH$; integrate against λ_0. The lower bound is the same.

(iv) For the series core $\binom{\{g_{\text{out}},g_{\text{in}},g'\}}{2}$ with F'' at g', F_{l+1} is the series connection of F_l and F'', so 23.14(i) gives $f_{F_{l+1}} = f_{F''}f_{F_l}$, and the hinge-wall formula with the mass 0 at g_{in}, the marks $\{g_{\text{in}}\} \sqcup B''$ and the ranks $2 + r_{\mathcal{A}''_j} - 1$, gives $\kappa_U = m_{B''} - \sum_j \left(s_j r_{\mathcal{A}''_j} + t_j(|B''| - r_{\mathcal{A}''_j})\right) = \kappa_{F''} - |\mathbf{s}|$. For the parallel core the ranks are $r_{\mathcal{A}''_j}$, the formula gives $\kappa_{F''} - |\mathbf{t}|$, and 23.14(ii) gives the product of the dual transforms. □

Theorem 24.5 (The weight of a hinge). *As stated: (i) for cell families with plain tables, one weight per table; (ii) to (iv) are the reference's, for one cell.*

Proof. (i) The bases through g carry the monomials of $K_{\mathcal{A}_j/g}$ and of $\Psi_{\mathcal{A}_j/g}$, which are multiplied by w_j; the deletions keep their weights (the reference proof of 24.5(i), table by table). So the hinge wall is kept, $\gamma^K_{\mathcal{A}_j} = K_{\mathcal{A}_j\setminus g}/K_{\mathcal{A}_j/g}$ becomes $\gamma^K_{\mathcal{A}_j}/w_j$ and $\gamma^\Psi_{\mathcal{A}_j} = \Psi_{\mathcal{A}_j/g}/\Psi_{\mathcal{A}_j\setminus g}$ becomes $w_j\gamma^\Psi_{\mathcal{A}_j}$; the coordinates of the ratio vector become $(w_1/w_j)\gamma^K_{\mathcal{A}_j}/\gamma^K_{\mathcal{A}_1}$ and $w_1w_j\gamma^\Psi_{\mathcal{A}_j}/\gamma^K_{\mathcal{A}_1}$, and the base form $u^{\mathbf{m}-\mathbf{1}}\prod_j K_{\mathcal{A}_j/g}^{-s_j}\Psi_{\mathcal{A}_j\setminus g}^{-t_j}(\gamma^K_{\mathcal{A}_1})^{-\kappa_F}\,d\omega$ is multiplied by $\prod_j w_j^{-s_j}\cdot w_1^{\kappa_F}$. In the orthant forms, $x_j/\gamma^K_{\mathcal{A}_j}$ becomes $w_jx_j/\gamma^K_{\mathcal{A}_j}$ and $y_j\gamma^\Psi_{\mathcal{A}_j}$ becomes $w_jy_j\gamma^\Psi_{\mathcal{A}_j}$ with the measure of f_F unchanged, and for $\check{f}_F$ the measure is multiplied by $\prod_j w_j^{-s_j-t_j}$ while $x_j/\gamma^\Psi_{\mathcal{A}_j}$ and $y_j\gamma^K_{\mathcal{A}_j}$ are divided by w_j. For one cell, $w_1 = w$: the ratio becomes $w^2\varrho_{\mathcal{A}}$, the base form $w^{\kappa_{\mathcal{A}}-s}\phi_{\mathcal{A}}$, and the homogeneity of 23.1 with $c = w$ gives $f_{w\mathcal{A}}(y) = f_F(w,wy) = w^{\kappa_{\mathcal{A}}-s}f_{\mathcal{A}}(w^2y)$, and with $c = 1/w$, $\check{f}_{w\mathcal{A}}(y) = w^{-s-t}\check{f}_F(1/w, y/w) = w^{-s-\kappa_{\mathcal{A}}}\check{f}_{\mathcal{A}}(y/w^2)$. (ii) to (iv) are the reference's. □

Remark. For a family the weights act on the law through an N-dimensional subtorus of $(0,\infty)^{2N-1}$, and the Mellin transform in $\mathbf{w}$ is a restricted Mellin transform of the law against the transform of the room, without the product formula of (ii); (iii) and (iv) concern the one-variable expansions of the node of width one. So (ii) to (iv) are stated for one cell.

Proposition 24.6 (Carrying a calculation through a change). *As stated, for a family whose tables have a common hinge tree.*

Proof. (i) and (iii) are 23.18(iii) with the recursion of 23.17(i): the law at a vertex is recomputed from the new law of the vertex directly below it on the path and the kept laws of the others, and the root by 23.17(ii). (ii) is 24.5(i) for the cell family F_v: the weight of the hinge multiplies the base form by $w_1^{\kappa_{F_v}}\prod_j w_j^{-s_j}$ and moves the ratio vector by the stated map, so the law is multiplied

by that factor and carried by that map; the cell families below v are unchanged, and above v the change of the law of F_v is a change at a vertex directly below, carried by (i). $\square$

50.25 Chapter 25: holds and the lean convolution

In this section $F = ((\mathcal{B}_j, \theta_j); s_j, t_j)_{j=1}^N$ is a family as in Definition 25.8: its tables are each one molecule on $\mathcal{E}$, $n = |\mathcal{E}| \geq 2$, and its exponents are positive, unless a statement says otherwise. Its $2N$ letters are written X, running over $K_1, \dots, K_N, \Psi_1, \dots, \Psi_N$. The letter X of table j has the exponent w_X, which is s_j or t_j, the degree $\deg X$, which is r_j or r_j^*, the twist $\mathbf{x}^X$, which is $\mathbf{x}_j^K$ or $\mathbf{x}_j^\Psi$, and the Newton polytope $\mathcal{N}_X$, which is $P(\mathcal{B}_j)$ or $P(\mathcal{B}_j^*)$; for masses $\mathbf{a}$ with $|\mathbf{a}| = w_X \deg X$ the period of its one-letter word X^{-w_X} is written $P_X(\mathbf{a})$, which is $P_{\mathcal{B}_j}(\mathbf{a}; s_j, 0)$ or $P_{\mathcal{B}_j}(\mathbf{a}; 0, t_j)$. $\mathcal{X}'$ is the set of the $2N-1$ letters other than K_1, and in a split $\mathbf{m} = \sum_X \mathbf{a}^X$ the load of X is $\mathbf{a}^X$, so that $\mathbf{a}^{K_j} = \mathbf{a}_j$ and $\mathbf{a}^{\Psi_j} = \mathbf{b}_j$.

Two facts are used throughout. First, the base polytope of a table that is one molecule, and that of its dual table, have dimension $n-1$: if $w \in \mathbb{R}^{\mathcal{E}}$ is orthogonal to every difference $\mathbf{1}_T - \mathbf{1}_{T'}$ of bases, then $\langle w, \mathbf{1}_T \rangle$ is constant over the bases and w is constant by Lemma 7.8; so these differences span $\mathbf{1}^\perp$, and so do the differences $\mathbf{1}_{\mathcal{E}\setminus T'} - \mathbf{1}_{\mathcal{E}\setminus T}$. Second, a point $\sum_k p_k v_k$ with every $p_k > 0$ and $\sum_k p_k = 1$ lies in the relative interior of the convex hull of the finitely many points v_k: for $x = \sum_k q_k v_k$ in the hull and $0 < \varepsilon \leq \min_k p_k$, the point $\sum_k p_k v_k + \varepsilon\big(\sum_k p_k v_k - x\big) = \sum_k \big((1+\varepsilon)p_k - \varepsilon q_k\big) v_k$ has nonnegative coefficients of sum 1; so every segment from a point of the hull to the given point extends beyond it within the hull, which characterizes the relative interior of a convex set.

Definition 25.1 (Positive letters; Newton words and sums). As stated: the period of a product of powers of positive letters at complex exponents, wherever it converges absolutely, a Newton word being the case of positive exponents.

Remark. The independence of the section is the proof of Lemma 16.2, which uses of the integrand $f = \alpha^{\mathbf{m}-\mathbf{1}} W$ only that it is measurable, homogeneous, $f(\lambda\alpha) = \lambda^{-n} f(\alpha)$ for $\lambda > 0$ when $m_{\mathcal{E}} = D$, and absolutely integrable over one section; here $|f| = \alpha^{\operatorname{Re}\mathbf{m}-\mathbf{1}} \prod_i L_i^{-\operatorname{Re} w_i}$. The family word at any exponents is a product of powers of its letters with $D = \sum_j (s_j r_j + t_j r_j^*)$, and on the balance wall its period is that of Theorem 8.7.

Proposition 25.3 (One positive letter). *As stated.*

Proof. Put $D = \deg L$ and $t = (t_k)_k$. Every t_k has $|t_k| = D$, and $\mathcal{N}_L$ has dimension $n-1$ in the hyperplane $|x| = D$, which does not contain 0; so the t_k span $\mathbb{R}^{\mathcal{E}}$.

(i) By Lemma 2.7, $x = \rho u$ with $\rho > 0$ and $u \in \Delta_{\mathcal{E}}$ gives $x^{\mathbf{a}-\mathbf{1}} dx = \rho^{|\mathbf{a}|-1} u^{\mathbf{a}-\mathbf{1}} d\rho\, d\omega_{\mathcal{E}}(u)$, and $L(\rho u) = \rho^D L(u)$. For $\operatorname{Re}|\mathbf{a}| > 0$ the substitution $\sigma = \rho^D L(u)$ gives

$$\int_0^\infty \rho^{|\mathbf{a}|-1} e^{-\rho^D L(u)}\, d\rho = \frac{\Gamma(w)}{D}\, L(u)^{-w}, \qquad w = |\mathbf{a}|/D.$$

So $\mathsf{G}_{\mathbf{a};t}((c_k)_k) = \frac{\Gamma(w)}{D} \int_{\Delta_{\mathcal{E}}} u^{\mathbf{a}-\mathbf{1}} L(u)^{-w} d\omega_{\mathcal{E}}(u) = \frac{\Gamma(w)}{D}\, P_{L^{-w}}(\mathbf{a})$, the last integral being the period over the section $\Delta_{\mathcal{E}}$ (Definition 25.1). The same computation at $\operatorname{Re}\mathbf{a}$, by Tonelli's theorem, shows that the two integrals converge absolutely together.

(ii) $|u^{\mathbf{a}-\mathbf{1}} L(u)^{-w}| = u^{\operatorname{Re}\mathbf{a}-\mathbf{1}} L(u)^{-\operatorname{Re} w}$, so $P_{L^{-w}}(\mathbf{a})$ converges absolutely exactly when the period of the Newton word $L^{-\operatorname{Re} w}$, $\operatorname{Re} w > 0$, converges at $\operatorname{Re}\mathbf{a}$. Its Newton sum is $(\operatorname{Re} w)\mathcal{N}_L$, of dimension $n-1$, and Theorem 25.2 gives the condition $\operatorname{Re}\mathbf{a} \in \operatorname{ri}\big((\operatorname{Re} w)\mathcal{N}_L\big) = (\operatorname{Re} w)\operatorname{ri}\mathcal{N}_L$.

(iii) For real $\mathbf{a}$ and $|\boldsymbol{\eta}| = 0$ the exponent w is the same real number at $\mathbf{a}$ and at $\mathbf{a} + i\boldsymbol{\eta}$, so by (i) $P_{L^{-w}}(\mathbf{a} + i\boldsymbol{\eta}) = D\,\mathsf{G}_{\mathbf{a}+i\boldsymbol{\eta};t}((c_k)_k)/\Gamma(w)$. If $P_{L^{-w}}(\mathbf{a})$ converges, so does $\mathsf{G}_{\mathbf{a};t}$, and $\mathbf{a} \in \operatorname{int}\operatorname{cone}(t)$ (Theorem 2.2). Theorem 2.11 gives $|\mathsf{G}_{\mathbf{a}+i\boldsymbol{\eta};t}((c_k)_k)| \le \mathsf{G}_{\mathbf{a};t}(\lambda(c_k)_k)\, e^{-(1-\varepsilon)h_t(\boldsymbol{\eta})}$ with $\lambda = \sin\frac{\pi\varepsilon}{2}$, and $h_t = h_L$ is a norm since the t_k span. Every t_k having total D, the substitution $x = \lambda^{-1/D}y$ gives $\mathsf{G}_{\mathbf{a};t}(\lambda(c_k)_k) = \lambda^{-w}\mathsf{G}_{\mathbf{a};t}((c_k)_k)$; multiplying by $D/\Gamma(w)$ gives the second bound. The bound by $P_{L^{-w}}(\mathbf{a})$ itself is that of the modulus of the integrand by its value at the real parts. □

Remark. At the letter $K_{\mathcal{H}}$ of a table that is one molecule, with the support $(\mathbf{1}_T)_T$, the coefficients $\boldsymbol{\theta}$ and $\mathcal{N}_{K_{\mathcal{H}}} = P(\mathcal{H})$, items (i), (ii) and (iii) are Proposition 25.10(i), (ii) and (iv) at the full basis lean, and at $\Psi_{\mathcal{H}}$ at the full cobasis lean. At a simplicial letter, (i) with Corollary 2.6 at the square configuration t is Proposition 25.6: $\mathsf{G}_{\mathbf{a};t}((c_k)_k) = |\det t|^{-1}\prod_k \Gamma(b_k)c_k^{-b_k}$ with $\mathbf{b} = t^{-1}\mathbf{a}$, and $|\mathbf{b}| = w$ since $\mathbf{1}^{\mathsf{T}}t = D\mathbf{1}^{\mathsf{T}}$.

Lemma 25.7 (Concatenation of Grammas). *As stated, for any number of parts.*

Proof. For $i \ge 2$ the configuration $t^{(i)}$ spans $\mathbb{R}^{\mathcal{E}}$, so by Theorem 2.11 the Gramma $\mathsf{G}_{\mathbf{w};t^{(i)}}(\boldsymbol{\xi}^{(i)})$ on $\mathbf{c}_i + i\mathbb{R}^{\mathcal{E}}$ is at most a constant times $e^{-(1-\varepsilon)h_{t^{(i)}}(\operatorname{Im}\mathbf{w})}$, $h_{t^{(i)}}$ a norm, and is integrable there. In $\mathbf{y} = \log x$ it is the Fourier transform of the continuous integrable function $e^{\langle \mathbf{c}_i,\mathbf{y}\rangle}\exp\big(-\sum_k \xi_k^{(i)} e^{\langle t_k^{(i)},\mathbf{y}\rangle}\big)$ (Definition 2.1), so Fourier inversion gives, for every $x \in \mathbb{R}^{\mathcal{E}}_{>0}$,

$$\exp\Big(-\sum_k \xi_k^{(i)} x^{t_k^{(i)}}\Big) = \frac{1}{(2\pi i)^n}\int_{\mathbf{c}_i + i\mathbb{R}^{\mathcal{E}}} \mathsf{G}_{\mathbf{w}_i;t^{(i)}}(\boldsymbol{\xi}^{(i)})\, x^{-\mathbf{w}_i}\, d\mathbf{w}_i.$$

Multiply these for $i = 2,\dots,p$ by $x^{\nu-\mathbf{1}}\exp\big(-\sum_k \xi_k^{(1)}x^{t_k^{(1)}}\big)$ and integrate over x. The modulus of the integrand is $x^{\operatorname{Re}\nu-\sum_{i\ge2}\mathbf{c}_i-\mathbf{1}}\exp\big(-\sum_k \xi_k^{(1)}x^{t_k^{(1)}}\big)\prod_{i\ge2}|\mathsf{G}_{\mathbf{w}_i;t^{(i)}}(\boldsymbol{\xi}^{(i)})|$, whose integral is $\mathsf{G}_{\operatorname{Re}\nu-\sum_{i\ge2}\mathbf{c}_i;t^{(1)}}(\boldsymbol{\xi}^{(1)})\prod_{i\ge2}\int|\mathsf{G}_{\mathbf{w}_i;t^{(i)}}(\boldsymbol{\xi}^{(i)})|\,|d\mathbf{w}_i|$, finite by Theorem 2.2 since $\operatorname{Re}\nu - \sum_{i\ge2}\mathbf{c}_i \in \operatorname{int}\operatorname{cone}(t^{(1)})$. So Fubini's theorem exchanges the integrals; the integral over x is $\mathsf{G}_{\nu-\sum_{i\ge2}\mathbf{w}_i;t^{(1)}}(\boldsymbol{\xi}^{(1)})$, and the left side is the Gramma of the concatenation (Definition 2.1). □

Definition 25.8 (Holding). As stated: the hold of a family, the Mellin transform in the twists of its letters other than K_1.

Remark. That the bases of every table span $\mathbb{R}^{\mathcal{E}}$ is the first fact above. By the torus relation of Definition 22.1, a factor $\mu > 0$ on every coordinate of one twist $\mathbf{x}^X$ multiplies the period by $\mu^{-w_X \deg X}$, and a twist of every letter by one vector $\boldsymbol{\lambda}$ multiplies it by $\boldsymbol{\lambda}^{-\mathbf{m}}$; so the Mellin transform in all the twists of all the letters at all the marks diverges, and the hold keeps the twist of K_1 at $\mathbf{1}$ and, in Lemma 25.11, the twists at one mark.

Definition 25.9 (Loads; admissible points). As stated: the loads and the admissible points of a family, an admissible point of one table being named by its Ψ-load.

Proposition 25.10 (The periods at the two full leans). *As stated; (iii) is stated for every family, and the closing sentence is new.*

Proof. Items (i), (ii) and (iv) concern one table $\mathcal{H}$ of F, one molecule, and are the reference, proof of prop:fullleans. The closing sentence is Proposition 25.3, proved above; at the letter $K_{\mathcal{H}}$, with the support $(\mathbf{1}_T)_T$, the coefficients $\boldsymbol{\theta}$ and the Newton polytope $P(\mathcal{H})$ of dimension $n-1$, it gives back (i), (ii) and (iv) at the full basis lean, and at $\Psi_{\mathcal{H}}$ at the full cobasis lean.

(iii) Let α be a gauge. By Theorem 7.16, $R_j(\alpha) = \mathbb{E}_{T\sim\mathbb{P}_{j,\alpha}}[\mathbf{1}_T] = \sum_{T\in\mathcal{B}_j}\mathbb{P}_{j,\alpha}(T)\,\mathbf{1}_T$ with $\mathbb{P}_{j,\alpha}(T) = \theta_{j,T}\alpha^T/K_j(\alpha) > 0$ for every basis, and $R^*_{j,e}(\alpha) = \mathbb{P}^*_{j,\alpha}(e \notin T)$, so $R^*_j(\alpha) = \sum_T \mathbb{P}^*_{j,\alpha}(T)\,\mathbf{1}_{\mathcal{E}\setminus T}$ with $\mathbb{P}^*_{j,\alpha}(T) = \theta_{j,T}\alpha^{\mathcal{E}\setminus T}/\Psi_j(\alpha) > 0$. By the second fact above $R_j(\alpha) \in \operatorname{ri} P(\mathcal{B}_j)$ and $R^*_j(\alpha) \in \operatorname{ri} P(\mathcal{B}^*_j)$, the two polytopes being the convex hulls of the $\mathbf{1}_T$ and of the $\mathbf{1}_{\mathcal{E}\setminus T}$.

Let $\mathbf{m}$ be real on the balance wall with every proper wall positive. A mark of a table that is one molecule on at least two marks is neither a loop nor a coloop, so $d_j(\{e\}) = d^*_j(\{e\}) = 0$ and $m_e = \kappa_{\{e\}} > 0$ for every e (Definition 8.1). A nonempty proper S with $c_j(S) = 0$ would have $|T \cap S|$ constant over the bases of table j, and so would be a union of molecules of it by Lemma 7.10, which is impossible, table j being one molecule; so $c_j(S) > 0$ in every table, every table being active, and F is connected. By Theorem 8.19(ii) and (iii) a native gauge $\alpha^\star$ exists, the target being $\mathbf{m}$ on the balance wall (Definition 8.17) and the walls at the target positive. Its usage is the target, $\sum_j \big(s_j R_j(\alpha^\star) + t_j R^*_j(\alpha^\star)\big) = \mathbf{m}$: the native loads are a split of $\mathbf{m}$ among the letters, with $|\mathbf{a}^\star_j| = s_j r_j$ and $|\mathbf{b}^\star_j| = t_j r^*_j$, every $\mathbf{1}_T$ having r_j marks and every $\mathbf{1}_{\mathcal{E}\setminus T}$ having r^*_j. By the preceding paragraph $\mathbf{a}^\star_j \in s_j \operatorname{ri} P(\mathcal{B}_j)$ and $\mathbf{b}^\star_j \in t_j \operatorname{ri} P(\mathcal{B}^*_j)$, so the native loads are admissible (Definition 25.9). □

Lemma 25.11 (Holding every mark separates the letters). *As stated, for every family.*

Proof. Let the data be real. By Theorem 8.7 the period of $F[\mathbf{x}]$ is the integral over the section $\{\alpha_{e_0} = 1\}$,

$$P_{F[\mathbf{x}]}(\mathbf{m};\mathbf{s},\mathbf{t}) = \int_{(0,\infty)^{\mathcal{E}\setminus e_0}} \alpha^{\mathbf{m}-\mathbf{1}} K_1(\alpha)^{-s_1} \prod_{X\in\mathcal{X}'} X(\mathbf{x}^X\circ\alpha)^{-w_X}\, d\alpha', \qquad \alpha = (\alpha', 1),$$

the twists at e_0 being 1 and the twist of K_1 being $\mathbf{1}$. Insert this into the hold and integrate first over the twists, by Tonelli's theorem, every function being positive. For fixed α' substitute $\mathbf{v}^X = \mathbf{x}^X\circ\alpha'$ on $\mathcal{E}\setminus e_0$ for every $X \in \mathcal{X}'$: then $(\mathbf{x}^X)^{\boldsymbol{\beta}^X-\mathbf{1}} d\mathbf{x}^X = \alpha'^{-\boldsymbol{\beta}^X}(\mathbf{v}^X)^{\boldsymbol{\beta}^X-\mathbf{1}} d\mathbf{v}^X$ and $X(\mathbf{x}^X\circ\alpha) = X(\mathbf{v}^X, 1)$, so the integral over $\mathbf{x}^X$ is $\alpha'^{-\boldsymbol{\beta}^X}$ times

$$\int_{(0,\infty)^{\mathcal{E}\setminus e_0}} (\mathbf{v}^X)^{\boldsymbol{\beta}^X-\mathbf{1}} X(\mathbf{v}^X,1)^{-w_X}\, d\mathbf{v}^X = P_X(\mathbf{a}^X),$$

the integral over the same section of the form of the one-letter word X^{-w_X} at the extension $\mathbf{a}^X$ of $\boldsymbol{\beta}^X$ of total $w_X \deg X$ (Theorem 8.7); here $\boldsymbol{\beta}^{K_j} = \boldsymbol{\beta}^K_j$ and $\boldsymbol{\beta}^{\Psi_j} = \boldsymbol{\beta}^\Psi_j$, and $\mathbf{a}^X$ is the $\mathbf{a}_j$ or $\mathbf{b}_j$ of the statement. What is left is $\int \alpha'^{\mathbf{m}'-\mathbf{1}-\sum_X \boldsymbol{\beta}^X} K_1(\alpha', 1)^{-s_1} d\alpha'$, $\mathbf{m}' = \mathbf{m}|_{\mathcal{E}\setminus e_0}$, which is $P_{K_1}(\mathbf{a}_1)$ for $\mathbf{a}_1 = \mathbf{m} - \sum_{X\in\mathcal{X}'} \mathbf{a}^X$: its coordinates off e_0 are $\mathbf{m}' - \sum_X \boldsymbol{\beta}^X$, and its total is $m_{\mathcal{E}} - \sum_{X\in\mathcal{X}'} w_X \deg X = r_1 s_1$ on the balance wall. This is the identity in $[0,\infty]$. For complex $\mathbf{m}$ and $\boldsymbol{\beta}$ the moduli of all the integrands are their values at the real parts, where the integrals converge by assumption, and Fubini's theorem replaces Tonelli's. □

Lemma S11. *Let shares $\mathbf{v} \in \mathbb{C}^M$ be pinned by $P\mathbf{v} = \boldsymbol{\pi}$, with q pins, as in Definition 4.1.*

(i) The fibre integral does not change when the shares are replaced by $A^{-1}\mathbf{v}$, the integrand by $f\circ A$ and the pins by PA, for a real $M\times M$ matrix A with $|\det A| = 1$, nor when the pins are replaced by $CP\mathbf{v} = C\boldsymbol{\pi}$, for a real $q\times q$ matrix C with $|\det C| = 1$.

(ii) Let $\mathbf{v} = (\mathbf{u},\mathbf{w})$ with $\mathbf{w} \in \mathbb{C}^q$, so that $P = (P_{\mathbf{u}}, P_{\mathbf{w}})$, and let $|\det P_{\mathbf{w}}| = 1$. Then

$$\int_{P\mathbf{v}=\boldsymbol{\pi}} f = \frac{1}{(2\pi i)^{M-q}} \int_{\mathbf{c}_{\mathbf{u}}+i\mathbb{R}^{M-q}} f\big(\mathbf{u}, P_{\mathbf{w}}^{-1}(\boldsymbol{\pi} - P_{\mathbf{u}}\mathbf{u})\big)\, d\mathbf{u},$$

$\mathbf{c}_{\mathbf{u}}$ the $\mathbf{u}$-part of the admissible real point, the two sides converging absolutely together.

(iii) Let $\mathbf{v} = (\mathbf{v}_0, \mathbf{v}_1, \dots, \mathbf{v}_k)$ and let the pins be the union of pins $P_l\mathbf{v}_l = \boldsymbol{\pi}_l$, each on one block. If the fibre integral of f converges absolutely, it is the integral over the fibre $P_0\mathbf{v}_0 = \boldsymbol{\pi}_0$ of the fibre integral over $P_1\mathbf{v}_1 = \boldsymbol{\pi}_1, \dots, P_k\mathbf{v}_k = \boldsymbol{\pi}_k$ at fixed $\mathbf{v}_0$, the inner one converging absolutely for almost every point of the outer imaginary translate.

Proof. For $\mathbf{y}_0 \in \mathbb{R}^q$ let $\mu_{P,\mathbf{y}_0} = (\det PP^{\mathsf{T}})^{-1/2}\mathrm{vol}_{M-q}$ on $\{\mathbf{y} \in \mathbb{R}^M : P\mathbf{y} = \mathbf{y}_0\}$, so that the fibre integral is $(2\pi)^{q-M}\int f(\mathbf{c} + i\mathbf{y})\, d\mu_{P,\mathrm{Im}\,\boldsymbol{\pi}}(\mathbf{y})$. By the coarea formula for the linear map P, whose Jacobian is $(\det PP^{\mathsf{T}})^{1/2}$, these measures disintegrate Lebesgue measure, $\int_{\mathbb{R}^M}\varphi\, d\mathbf{y} = \int_{\mathbb{R}^q}\big(\int \varphi\, d\mu_{P,\mathbf{y}_0}\big)d\mathbf{y}_0$ for integrable φ, and $\mathbf{y}_0 \mapsto \int \varphi\, d\mu_{P,\mathbf{y}_0}$ is continuous for continuous φ of compact support; these two properties determine the family $(\mu_{P,\mathbf{y}_0})_{\mathbf{y}_0}$.

(i) The substitution $\mathbf{y} = A\mathbf{y}'$ preserves Lebesgue measure and carries the disintegration along PA to that along P; the substitution $\mathbf{y}_0 = C^{-1}\mathbf{y}_0'$ preserves Lebesgue measure on $\mathbb{R}^q$ and carries the disintegration along CP to that along P, with $\mu_{CP,C\mathbf{y}_0} = \mu_{P,\mathbf{y}_0}$. The admissible real point and the factor $(2\pi)^{q-M}$ do not change.

(ii) The map $\mathbf{y} \mapsto (\mathbf{y}_\mathbf{u}, P\mathbf{y})$ has the block triangular matrix $\begin{pmatrix} I & 0 \\ P_\mathbf{u} & P_\mathbf{w} \end{pmatrix}$, of determinant of modulus 1; so $d\mathbf{y} = d\mathbf{y}_\mathbf{u}\, d\mathbf{y}_0$, and $\mu_{P,\mathbf{y}_0}$ is the image of Lebesgue measure on $\mathbb{R}^{M-q}$ under $\mathbf{y}_\mathbf{u} \mapsto \big(\mathbf{y}_\mathbf{u}, P_\mathbf{w}^{-1}(\mathbf{y}_0 - P_\mathbf{u}\mathbf{y}_\mathbf{u})\big)$. With $\mathbf{u} = \mathbf{c}_\mathbf{u} + i\mathbf{y}_\mathbf{u}$ and $d\mathbf{u} = i^{M-q}d\mathbf{y}_\mathbf{u}$ this is the display; both sides are one integral against one measure.

(iii) The pin matrix is block diagonal, so the disintegration along it is the product of the disintegrations along the blocks, $\mu_{P,(\mathbf{y}_{0,l})_l} = \bigotimes_l \mu_{P_l,\mathbf{y}_{0,l}}$, and the factor $(2\pi)^{q-M}$ is the product of the factors of the blocks. Fubini's theorem gives the iterated integral. □

Remark. In Theorem 25.12(ii) the shares are the loads of the $2N$ letters, $M = 2Nn$, with the $q = n+2N-1$ pins $\sum_X \mathbf{a}^X = \mathbf{m}$ and $|\mathbf{a}^X| = w_X \deg X$ for $X \in \mathcal{X}'$, and the eliminated coordinates are $\mathbf{a}_1$ and the loads $a^X_{e_0}$, $X \in \mathcal{X}'$. With the rows ordered as the mass pins at $e \neq e_0$, the mass pin at e_0 and the totals, and the columns as $a_{1,e}$ for $e \neq e_0$, a_{1,e_0} and the $a^X_{e_0}$, the block $P_\mathbf{w}$ is

$$\begin{pmatrix} I_{n-1} & 0 & 0 \\ 0 & 1 & \mathbf{1}^{\mathsf{T}} \\ 0 & 0 & I_{2N-1} \end{pmatrix},$$

of determinant 1, and Lemma S11(ii) gives the coordinate form stated there, with the factor $(2\pi i)^{-(2N-1)(n-1)}$. With the further pins on G of Theorem 25.14 the loads a^X_e, $X \in \mathcal{X}'$, $e \in G$, are eliminated as well, each by its own pin with the coefficient 1, and the block stays unit upper triangular. The function `eliminated_block_det` of `checks/bookkeeping.py` computes this determinant exactly for $n \le 4$ and up to six letters.

Lemma S12. *Let $A, B > 0$, $w > 0$ and $c \in \mathbb{C}$. If $0 < \mathrm{Re}\, c < w$,*

$$\int_0^\infty x^{c-1}(A + xB)^{-w}\, dx = \Gamma\,{}_2^{}{}_1\!\left[\begin{matrix} c, & w-c \\ & w \end{matrix}\right] A^{c-w}B^{-c},$$

absolutely convergent; for real $c \notin (0, w)$ the integral is $+\infty$.

Proof. The substitution $x = (A/B)y$ gives $A^{c-w}B^{-c}\int_0^\infty y^{c-1}(1+y)^{-w}dy$. The last integral is the integral over the section $\{u_2 = 1\}$ of the form of the word $(u_1+u_2)^{-w}$ on two marks at the masses $(c, w-c)$: the family of the list $\binom{\{1,2\}}{1}$ with unit weights at the exponents $(w, 0)$, on its balance wall, whose walls are c and $w-c$. For $0 < \mathrm{Re}\, c < w$ its period converges absolutely (Theorem 8.7), and by Lemma 16.2 the integral equals that over $\Delta_{\{1,2\}}$, where $u_1 + u_2 = 1$; by Theorem 3.9 it is

$\int_\Delta u^{(c,w-c)-\mathbf{1}}d\omega = \Gamma_{\substack{2\\1}}\!\left[\begin{matrix} c,\ w-c \\ w \end{matrix}\right]$. For real $c \le 0$ the integrand is at least $2^{-w}y^{c-1}$ on $(0,1)$, and for real $c \ge w$ at least $2^{-w}y^{c-w-1}$ on $(1,\infty)$; both integrals diverge. □

Theorem 25.12 (The lean convolution). *As stated, for every family; the closing sentence takes the active letters of a family with nonnegative exponents.*

Proof. (i) Let $\mathbf{c}$ be admissible. By Proposition 25.10(ii), $\mathbf{c}_j^K \in s_j \operatorname{ri} P(\mathcal{B}_j)$ is the condition $(\mathbf{c}_j^K)_S > s_j d_j(S)$ for every nonempty proper S, and likewise $(\mathbf{c}_j^\Psi)_S > t_j d_j^*(S)$; summing over the letters, $\operatorname{Re}\kappa_S = \operatorname{Re} m_S - \sum_j \big(s_j d_j(S) + t_j d_j^*(S)\big) > 0$ (Definition 8.1). Conversely, if every proper wall of $\operatorname{Re}\mathbf{m}$ is positive, the native loads of $\operatorname{Re}\mathbf{m}$ are admissible for $(\mathbf{m};\mathbf{s},\mathbf{t})$ by Proposition 25.10(iii), admissibility involving $\operatorname{Re}\mathbf{m}$ only. The admissible points are cut out by linear equations and the convex conditions $\mathbf{c}^X \in w_X \operatorname{ri}\mathcal{N}_X$, so they form a convex set.

(ii) Apply Theorem 25.4 to the family word $W = \prod_X X^{-w_X}$ split into the $2N$ factors $W_X = X^{-w_X}$, of degrees $w_X \deg X$. The Newton polytope of W_X is $w_X\mathcal{N}_X$, of dimension $n-1$ by the first fact above, so its relative interior is $w_X \operatorname{ri}\mathcal{N}_X$, and the points $(\mathbf{c}_i)_i$ of Theorem 25.4 are exactly the admissible points. With the twists $\mathbf{x}^X$ of the factors, the left side of Theorem 25.4 is the integral over the section $\{\alpha_{e_0} = 1\}$ of the word of $F[\mathbf{x}]$, whose letters are $X(\mathbf{x}^X \circ \alpha)$ (Definition 22.1), that is $P_{F[\mathbf{x}]}(\mathbf{m};\mathbf{s},\mathbf{t})$ (Theorem 8.7); the periods of the factors are the $P_X(\mathbf{a}^X)$. This is the display, absolutely convergent, of dimension $(2N-1)(n-1)$; K_1 is taken as the last factor of Theorem 25.4, whose total pin is omitted, and that pin holds by the others and the balance wall. The coordinate form is the remark after Lemma S11.

(iii) For a real point $\mathbf{a}$ at which $P_X(\mathbf{a})$ converges, $|P_X(\mathbf{a}+i\mathbf{y})| \le P_X(\mathbf{a})$, the modulus of the integrand of a period being its value at the real parts, and $|(\mathbf{x}^X)^{-\mathbf{a}^X}| = (\mathbf{x}^X)^{-\operatorname{Re}\mathbf{a}^X}$. On the imaginary translate through $\mathbf{c}$ the imaginary part $\mathbf{y}^X$ of every load has $|\mathbf{y}^X| = 0$, by the pins, and Proposition 25.10(iv) bounds $|P_X(\mathbf{c}^X + i\mathbf{y}^X)|$ by $\big(\sin\frac{\pi\varepsilon}{2}\big)^{-w_X} e^{-(1-\varepsilon)h_X(\mathbf{y}^X)} P_X(\mathbf{c}^X)$, h_X the norm of that proposition for the letter X.

The closing sentence is Theorem 25.4 with one factor for each active letter, the inactive letters being the constant 1; any factor may be taken last, and the walls and the admissible points are read with the active letters alone. □

Corollary 25.13 (What a family retains). *As stated, for every family.*

Proof. By Theorem 25.12(ii) and its closing sentence every period of F and of its twists, at exponents $s_j, t_j \ge 0$ not all zero and at masses on the balance wall with every proper wall positive, is a fibre integral of products of the periods P_X of its active letters at their loads, times the twists. By Proposition 25.10(i), $P_{\mathcal{B}_j}(\mathbf{a}; s_j, 0) = r_j\, \mathsf{G}_{\mathbf{a};(\mathbf{1}_T)_T}(\boldsymbol{\theta}_j)/\Gamma(s_j)$ for $s_j > 0$, and by the same item and Cremona $P_{\mathcal{B}_j}(\mathbf{b}; 0, t_j) = P_{\mathcal{B}_j}(t_j\mathbf{1} - \mathbf{b}; t_j, 0) = r_j\, \mathsf{G}_{t_j\mathbf{1}-\mathbf{b};(\mathbf{1}_T)_T}(\boldsymbol{\theta}_j)/\Gamma(t_j)$ for $t_j > 0$. The loads run over $|\mathbf{a}| = r_j s_j$ and $|\mathbf{b}| = r_j^* t_j$, that is $|t_j\mathbf{1} - \mathbf{b}| = nt_j - r_j^* t_j = r_j t_j$. The converse is Proposition 25.10(i) for table j. □

Theorem 25.14 (Pinned holds). *As stated, for every family.*

Proof. Put $d = (2N-1)|G|$. In the coordinates of Theorem 25.12(ii), the loads of the letters of $\mathcal{X}'$ at the marks other than e_0, split the coordinates into their values $\mathbf{z}_G$ on G and the rest $\mathbf{z}'$, and let $\mathcal{I}(\mathbf{z}_G, \mathbf{z}')$ be the integrand at $\mathbf{x} = \mathbf{1}$, the product of the periods P_X at the loads that $(\mathbf{z}_G, \mathbf{z}')$ and the pins determine. Let $\mathbf{c}$ be the admissible point of the statement, $\boldsymbol{\beta} = \mathbf{c}_G$, and for $\mathbf{y} \in \mathbb{R}^d$ put

$$\Phi(\mathbf{y}) = \frac{1}{(2\pi i)^{(2N-1)(n-1-|G|)}} \int \mathcal{I}(\mathbf{c}_G + i\mathbf{y}, \mathbf{z}')\, d\mathbf{z}',$$

over the imaginary translate through $\mathbf{c}$ in $\mathbf{z}'$. By Lemma S11(ii) and the remark after it, $\Phi(\boldsymbol{\eta})$ is the fibre integral of the statement at $\boldsymbol{\beta}+i\boldsymbol{\eta}$.

(a) By Theorem 25.12(iii), $|\mathcal{I}|$ on the imaginary translate is at most a constant times $\prod_{X\in\mathcal{X}'} e^{-(1-\varepsilon)h_X(\mathbf{y}^X)}$, $\mathbf{y}^X$ the imaginary part of the load of X, a vector of total 0 determined by its coordinates off e_0; since h_X is a norm on the vectors of total 0, this bound is integrable in all the imaginary parts. So Φ is defined everywhere, continuous by dominated convergence, and integrable, with $\int|\Phi|\le(2\pi)^{(2N-1)(n-1-|G|)}\int|\mathcal{I}|$.

(b) For a twist at the marks of G alone, $\mathbf{x}^X=e^{\mathbf{u}^X}$ on G with $\mathbf{u}^X\in\mathbb{R}^G$ for $X\in\mathcal{X}'$ and $\mathbf{x}^{K_1}=\mathbf{1}$, the factor $\prod_X(\mathbf{x}^X)^{-\mathbf{a}^X}$ of Theorem 25.12(ii) is $e^{-\langle\mathbf{c}_G+i\mathbf{y},\mathbf{u}\rangle}$ on the translate, $\mathbf{u}=(\mathbf{u}^X)_X$. By Fubini's theorem in $(\mathbf{y},\mathbf{z}')$, $d\mathbf{z}_G=i^d\,d\mathbf{y}$,

$$e^{\langle\mathbf{c}_G,\mathbf{u}\rangle}P_{F[e^{\mathbf{u}}]}(\mathbf{m};\mathbf{s},\mathbf{t})=\frac{1}{(2\pi)^d}\int_{\mathbb{R}^d}\Phi(\mathbf{y})\,e^{-i\langle\mathbf{y},\mathbf{u}\rangle}\,d\mathbf{y}=:\widehat{\Phi}(\mathbf{u}).$$

(c) Let first $\mathbf{m}$ be real. Then $\widehat{\Phi}\ge0$, and for $\varepsilon>0$, by Fubini's theorem and the Gaussian integral,

$$\int_{\mathbb{R}^d}\widehat{\Phi}(\mathbf{u})\,e^{-\varepsilon|\mathbf{u}|^2/2}\,d\mathbf{u}=\int_{\mathbb{R}^d}\Phi(\mathbf{y})\,\frac{e^{-|\mathbf{y}|^2/(2\varepsilon)}}{(2\pi\varepsilon)^{d/2}}\,d\mathbf{y}\longrightarrow\Phi(\mathbf{0})\qquad(\varepsilon\downarrow0),$$

Φ being integrable and continuous at $\mathbf{0}$. By monotone convergence $\int\widehat{\Phi}\,d\mathbf{u}=\Phi(\mathbf{0})<\infty$, and with $d\mathbf{x}/\mathbf{x}=d\mathbf{u}$ this integral is $\mathrm{Hold}_G(\mathbf{c}_G)$: the statement at $\boldsymbol{\eta}=\mathbf{0}$.

(d) For complex $\mathbf{m}$, $|P_{F[\mathbf{x}]}(\mathbf{m};\mathbf{s},\mathbf{t})|\le P_{F[\mathbf{x}]}(\operatorname{Re}\mathbf{m};\mathbf{s},\mathbf{t})$, and $\mathbf{c}$ is admissible for $\operatorname{Re}\mathbf{m}$ as well; by (c) at $\operatorname{Re}\mathbf{m}$ the hold converges absolutely at every $\mathbf{c}_G+i\boldsymbol{\eta}$. Then $\widehat{\Phi}$ of (b) is integrable, Φ is integrable and continuous, and Fourier inversion gives, at every $\boldsymbol{\eta}$,

$$\mathrm{Hold}_G(\mathbf{c}_G+i\boldsymbol{\eta})=\int_{\mathbb{R}^d}e^{\langle\mathbf{c}_G+i\boldsymbol{\eta},\mathbf{u}\rangle}P_{F[e^{\mathbf{u}}]}(\mathbf{m};\mathbf{s},\mathbf{t})\,d\mathbf{u}=\int_{\mathbb{R}^d}\widehat{\Phi}(\mathbf{u})\,e^{i\langle\boldsymbol{\eta},\mathbf{u}\rangle}\,d\mathbf{u}=\Phi(\boldsymbol{\eta}).$$

At $G=\mathcal{E}\setminus e_0$ the fibre has dimension 0, and its value is the product of Lemma 25.11. □

Proposition 25.15 (Holding one mark). *As stated, for every family.*

Proof. Let the data be real. Take the section $\{h=1\}$ of Theorem 8.7 with $h(\alpha)=\sum_{e\ne g}\alpha_e$: on it $\alpha=(\alpha',\alpha_g)$ with $\alpha'\in\Delta_{\mathcal{E}\setminus g}$ and $\alpha_g\in(0,\infty)$, and the measure is $d\omega_{\mathcal{E}\setminus g}(\alpha')\,d\alpha_g$. By Definitions 22.1 and 21.1 the twist at g acts on the letters as

$$K_j(\mathbf{x}@g\circ\alpha)=K_{\mathcal{B}_j\setminus g}(\alpha')+x_j^K\alpha_gK_{\mathcal{B}_j/g}(\alpha'),\qquad\Psi_j(\mathbf{x}@g\circ\alpha)=x_j^\Psi\alpha_g\Psi_{\mathcal{B}_j\setminus g}(\alpha')+\Psi_{\mathcal{B}_j/g}(\alpha'),$$

the minors carrying the weights of table j, all four nonzero since g is neither a loop nor a coloop. Insert the period into the hold and integrate first over the twists of the letters of $\mathcal{X}'$, by Tonelli's theorem. By Lemma S12, for $j\ge2$, respectively for every j,

$$\int_0^\infty x^{a_j-1}\big(K_{\mathcal{B}_j\setminus g}+x\alpha_gK_{\mathcal{B}_j/g}\big)^{-s_j}dx=\Gamma_{\,1}^{\,2}\begin{bmatrix}a_j,\ s_j-a_j\\ s_j\end{bmatrix}K_{\mathcal{B}_j\setminus g}^{a_j-s_j}\big(\alpha_gK_{\mathcal{B}_j/g}\big)^{-a_j},$$
$$\int_0^\infty x^{b_j-1}\big(\Psi_{\mathcal{B}_j/g}+x\alpha_g\Psi_{\mathcal{B}_j\setminus g}\big)^{-t_j}dx=\Gamma_{\,1}^{\,2}\begin{bmatrix}b_j,\ t_j-b_j\\ t_j\end{bmatrix}\Psi_{\mathcal{B}_j/g}^{b_j-t_j}\big(\alpha_g\Psi_{\mathcal{B}_j\setminus g}\big)^{-b_j},$$

finite exactly when $0 < a_j < s_j$, respectively $0 < b_j < t_j$, and $+\infty$ otherwise. The power of α_g left is $\alpha_g^{m_g-1-\sum_{j\geq 2} a_j - \sum_j b_j} = \alpha_g^{a_1-1}$, and by the same lemma

$$\int_0^\infty \alpha_g^{a_1-1}\big(K_{\mathcal{B}_1\setminus g} + \alpha_g K_{\mathcal{B}_1/g}\big)^{-s_1} d\alpha_g = \Gamma_1^2\begin{bmatrix} a_1, & s_1 - a_1 \\ & s_1 \end{bmatrix} K_{\mathcal{B}_1\setminus g}^{a_1-s_1} K_{\mathcal{B}_1/g}^{-a_1},$$

finite exactly when $0 < a_1 < s_1$. What remains is

$$\int_{\Delta_{\mathcal{E}\setminus g}} \alpha'^{\mathbf{m}|_{\mathcal{E}\setminus g}-\mathbf{1}} \prod_j K_{\mathcal{B}_j\setminus g}^{-(s_j-a_j)}\, \Psi_{\mathcal{B}_j\setminus g}^{-b_j}\, K_{\mathcal{B}_j/g}^{-a_j}\, \Psi_{\mathcal{B}_j/g}^{-(t_j-b_j)}\, d\omega_{\mathcal{E}\setminus g},$$

the period of the children family $F_{\{g\}}\big((s_j-a_j,a_j),(b_j,t_j-b_j)\big)_j$ at $\mathbf{m}|_{\mathcal{E}\setminus g}$, which is on its balance wall (the paragraph before the proposition); it is finite exactly when every proper wall of it is positive (Theorem 8.7). The integrands being positive, the hold is the product of these factors in $[0,\infty]$ and is finite exactly when all of them are. For complex loads and masses whose real parts are such data the moduli are dominated by the real computation, Lemma S12 holds in the strip, and Fubini's theorem gives the same identity. The sentence on admissible points is Theorem 25.14 with $G = \{g\}$.

For the limits, let the letter Y have the exponent $u > m_g > 0$ and let the twists at g of the other letters decrease to 0. Each other letter decreases pointwise to one of its minors, $K_{\mathcal{B}_j\setminus g}$ or $\Psi_{\mathcal{B}_j/g}$, and its power with a negative exponent increases; by monotone convergence the period increases to the integral of the limit. In the limit only Y contains α_g, as $A+\alpha_g B$ with A and B its two minors, and by Lemma S12 the integral over α_g of $\alpha_g^{m_g-1}(A+\alpha_g B)^{-u}$ is $\Gamma_1^2\begin{bmatrix} m_g, & u-m_g \\ & u \end{bmatrix} A^{m_g-u}B^{-m_g}$. What is left is the period of the children family at the shares of the statement: for $Y = K_j$, $A = K_{\mathcal{B}_j\setminus g}$ carries the exponent $s_j - m_g$ and $B = K_{\mathcal{B}_j/g}$ the exponent m_g; for $Y = \Psi_j$, $A = \Psi_{\mathcal{B}_j/g}$ carries $t_j - m_g$ and $B = \Psi_{\mathcal{B}_j\setminus g}$ carries m_g; every other $K_{j'}$ is $K_{\mathcal{B}_{j'}\setminus g}$ at $s_{j'}$ and every other $\Psi_{j'}$ is $\Psi_{\mathcal{B}_{j'}/g}$ at $t_{j'}$. □

Remark. For one table a twist at g in the cobasis letter is $x = x_1^\Psi$ with $x_1^K = 1$ (Definition 22.1), and $x \downarrow 0$ is the limit with the letter K chosen. With the letter Ψ chosen the twist y of K decreases to 0 with that of Ψ at 1; by the torus relation of Definition 22.1 at the mark g, $P_{\mathcal{H}[(y,1)@g]} = y^{-m_g} P_{\mathcal{H}[(1,1/y)@g]} = x^{m_g} P_{\mathcal{H}[x@g]}$ with $x = 1/y$. So the two limits are those of $P_{\mathcal{H}[x@g]}$ as $x \downarrow 0$ and of $x^{m_g} P_{\mathcal{H}[x@g]}$ as $x \uparrow \infty$, as the paragraph after the proposition reads them.

Lemma 25.16 (The Mellin transform of a law is the period of a children family). *As stated, for every cell family.*

Proof. By Definitions 23.1 and 21.1, with $\sum_j (z_{j,K} + z_{j,\Psi}) = \kappa_F$ the power of $\gamma_{\mathcal{A}_1}^K$ in $\boldsymbol{\varrho}_F^{-\mathbf{z}}\, d\phi_F$ is $-\kappa_F + \sum_{j\geq 2} z_{j,K} + \sum_j z_{j,\Psi} = -z_{1,K}$. With $\gamma_{\mathcal{A}_j}^K = K_{\mathcal{A}_j\setminus g}/K_{\mathcal{A}_j/g}$ and $\gamma_{\mathcal{A}_j}^\Psi = \Psi_{\mathcal{A}_j/g}/\Psi_{\mathcal{A}_j\setminus g}$,

$$\begin{aligned} \boldsymbol{\varrho}_F^{-\mathbf{z}}\, d\phi_F &= u^{\mathbf{m}-\mathbf{1}} \prod_j K_{\mathcal{A}_j/g}^{-s_j}\, \Psi_{\mathcal{A}_j\setminus g}^{-t_j} \big(\gamma_{\mathcal{A}_j}^K\big)^{-z_{j,K}} \big(\gamma_{\mathcal{A}_j}^\Psi\big)^{-z_{j,\Psi}}\, d\omega_B \\ &= u^{\mathbf{m}-\mathbf{1}} \prod_j K_{\mathcal{A}_j\setminus g}^{-z_{j,K}}\, \Psi_{\mathcal{A}_j\setminus g}^{-(t_j-z_{j,\Psi})}\, K_{\mathcal{A}_j/g}^{-(s_j-z_{j,K})}\, \Psi_{\mathcal{A}_j/g}^{-z_{j,\Psi}}\, d\omega_B. \end{aligned}$$

This is the form of the children family of $\{g\}$ at the shares of the statement, its tables $\mathcal{A}_j \setminus g$, of rank $r_{\mathcal{A}_j}$ and corank $|B| - r_{\mathcal{A}_j}$, at $(z_{j,K}, t_j - z_{j,\Psi})$ and $\mathcal{A}_j/g$, of rank $r_{\mathcal{A}_j} - 1$ and corank $|B| - r_{\mathcal{A}_j} + 1$, at $(s_j - z_{j,K}, z_{j,\Psi})$. Its degree is

$$\sum_j \Big(r_{\mathcal{A}_j} z_{j,K} + (|B| - r_{\mathcal{A}_j})(t_j - z_{j,\Psi}) + (r_{\mathcal{A}_j} - 1)(s_j - z_{j,K}) + (|B| - r_{\mathcal{A}_j} + 1) z_{j,\Psi} \Big)$$
$$= \kappa_F + \sum_j \big(s_j (r_{\mathcal{A}_j} - 1) + t_j (|B| - r_{\mathcal{A}_j}) \big) = m_B,$$

so the children family is on its balance wall, and the integral over Δ_B is its period (Theorem 8.7), in $[0, \infty]$ for real $\mathbf{z}$. This is the first identity.

With the mass $\sum_j (s_j + t_j) - \kappa_F$ on g the family of the tables $\mathcal{A}_j$ is on its balance wall (Lemma 21.12). Apply Proposition 25.15 to it at the mark g, a hinge and so neither a loop nor a coloop, with $a_j = s_j - z_{j,K}$ for $j \geq 2$ and $b_j = t_j - z_{j,\Psi}$. Then

$$a_1 = \sum_j (s_j + t_j) - \kappa_F - \sum_{j \geq 2} (s_j - z_{j,K}) - \sum_j (t_j - z_{j,\Psi}) = s_1 - z_{1,K},$$

the children family of Proposition 25.15 at the shares $(s_j - a_j, a_j) = (z_{j,K}, s_j - z_{j,K})$ and $(b_j, t_j - b_j) = (t_j - z_{j,\Psi}, z_{j,\Psi})$ is that of the first identity, its Beta corners are $\Gamma \begin{matrix} 2 \\ 1 \end{matrix} \begin{bmatrix} s_j - z_{j,K}, & z_{j,K} \\ & s_j \end{bmatrix}$ and $\Gamma \begin{matrix} 2 \\ 1 \end{matrix} \begin{bmatrix} t_j - z_{j,\Psi}, & z_{j,\Psi} \\ & t_j \end{bmatrix}$, and its hold is the left side of the second identity. At the real part of $\mathbf{z}$ the conditions of Proposition 25.15 hold: $0 < a_j < s_j$ and $0 < b_j < t_j$ are $0 < \operatorname{Re} z_{j,K} < s_j$ and $0 < \operatorname{Re} z_{j,\Psi} < t_j$, and the walls of the children family are positive since its period, $\int \boldsymbol{\varrho}_F^{-\operatorname{Re} \mathbf{z}} d\phi_F$ by the first identity, is finite. So Proposition 25.15 gives the second identity for complex $\mathbf{z}$ with this real part. □

Remark. The balance of the children family, the balance of the family of the tables $\mathcal{A}_j$ with the mass $\sum_j (s_j + t_j) - \kappa_F$ on g, and the identity $a_1 = s_1 - z_{1,K}$ are computed exactly by `check_hingesplit_balance` in `checks/bookkeeping.py`, and the balance of the children family of Proposition 25.15 by `check_holdone_balance`.

50.26 Chapter 26: periods at the full leans and networks along a hinge tree

The notation of Section 50.25 is kept. When table j of a family carries a hinge tree $\mathfrak{T}_j$ as in Definition 26.2, its marker loads and node loads are read in table j (Definition 26.3), at its loads $(\mathbf{a}_j, \mathbf{b}_j)$ and its exponents (s_j, t_j).

Lemma 26.1 (Substitutions of molecules). *As stated, for any number of cells.*

Proof. The case of two cells is the reference, proof of lem:twosummol. By Proposition 21.3(i) the substitution is the gluing of the cells to $\mathcal{H}$ along its marks one at a time: $\mathcal{B}_0 = \mathcal{H}$, and $\mathcal{B}_i$ is the gluing of $\mathcal{A}_i$ and $\mathcal{B}_{i-1}$ along h_i, the marks $h_{i+1}, \ldots, h_q$ left in place. By Definition 21.1 and Proposition 21.3(iii) this gluing is the two-sum of $\mathcal{A}_i$ and $\mathcal{B}_{i-1}$, the latter read as a cell with the hinge h_i. This h_i is neither a loop nor a coloop of $\mathcal{B}_{i-1}$: $\mathcal{H}$ has bases through h_i and bases avoiding it, and each extends to a basis of $\mathcal{B}_{i-1}$ by bases of the hinge minors of the cells glued before, which exist since their hinges are neither loops nor coloops. By the case of two cells $\mathcal{B}_i$ is one molecule exactly when $\mathcal{A}_i$ and $\mathcal{B}_{i-1}$ are, and by induction $\mathcal{B}_q$ is one molecule exactly when $\mathcal{H}$ and all the $\mathcal{A}_i$ are. □

Corollary 26.6 (Convergence is decided at the nodes). *As stated, for every family.*

Proof. Every table is one molecule by Lemma 26.1 applied along its hinge tree. By Theorem 26.5 in table j, at real loads, $P_{\mathcal{B}_j}(\mathbf{a}_j; s_j, 0)$ is finite exactly when every marker load $k_{j;v,\mathfrak{e}}$ lies in $(0, s_j)$ and the period of every node at its full basis lean is finite at its node loads. By Proposition 25.10(ii) at the node, one molecule, the latter is $(\mathbf{a}_{j,v})_S > s_j d_{j,v}(S)$ for every nonempty proper S of its marks and markers; at $S = \{g\}$ and at the complement of a marker g these inequalities are $k > 0$ and $k < s_j$ for the marker load k at g, since g is neither a loop nor a coloop of the node and $|\mathbf{a}_{j,v}| = r_{j,v} s_j$ (Lemma 26.4(ii)). Likewise at the full cobasis lean. So the node inequalities hold at a split exactly when every load is admissible for its letter (Proposition 25.10(ii) in table j), that is when the split is an admissible point, and by Theorem 25.12(i) such a point exists exactly when every proper wall is positive; the native loads are one. The unknowns are the loads of the $2N$ letters at n marks less $n + 2N - 1$ independent pins, $(2N-1)(n-1)$ of them, and the node v of table j contributes $2(2^{|\mathcal{E}_{j,v}|+|G_{j,v}|} - 2)$ inequalities. □

Proposition 26.9 (Series and parallel nodes at their full leans). *As stated; the last sentence, which reads the four closed forms off Proposition 25.6, is new.*

Proof. The closed forms are the reference, proof of prop:spleans. The letter K of $\binom{\mathcal{X}}{1}$ is $\sum_x \theta_x \alpha_x$, and so is the letter Ψ of $\binom{\mathcal{X}}{q}$, whose basis $\mathcal{X} \setminus x$ has the cobasis $\{x\}$: both are simplicial with the configuration $I = (\mathbf{e}_x)_x$, of degree 1, $|\det I| = 1$ and the shares $\mathbf{b} = \mathbf{a}$, and Proposition 25.6 gives $\Gamma_{\substack{q+1\\1}}\begin{bmatrix}\mathbf{a}\\|\mathbf{a}|\end{bmatrix} \prod_x \theta_x^{-a_x}$, the forms of $P_{\binom{\mathcal{X}}{1}}(\mathbf{a}; s, 0)$ and $P_{\binom{\mathcal{X}}{q}}(\mathbf{b}; 0, t)$. The letter K of $\binom{\mathcal{X}}{q}$ and the letter Ψ of $\binom{\mathcal{X}}{1}$ are $\sum_x \theta_x \alpha^{\mathcal{X}\setminus x}$, simplicial with the configuration $J - I = (\mathbf{1} - \mathbf{e}_x)_x$ of degree q, J the matrix of ones. $J - I$ has the eigenvalues q, once, and -1, q times, so $|\det(J - I)| = q$, and $(J - I)^{-1} = \frac{1}{q} J - I$, so the shares of $\mathbf{a}$ with $|\mathbf{a}| = qs$ are $\frac{|\mathbf{a}|}{q}\mathbf{1} - \mathbf{a} = (s - a_x)_x$, of sum s. Proposition 25.6 gives $\frac{q}{q}\Gamma_{\substack{q+1\\1}}\begin{bmatrix}(s-a_x)_x\\ s\end{bmatrix} \prod_x \theta_x^{a_x - s}$, the form of $P_{\binom{\mathcal{X}}{q}}(\mathbf{a}; s, 0)$, and in the same way that of $P_{\binom{\mathcal{X}}{1}}(\mathbf{b}; 0, t)$ with $|\mathbf{b}| = qt$. The criteria of convergence agree, the positivity of the real parts of the shares being that of the arguments of the Gammas. □

Remark. The function `check_spleans_is_simplicial` of `checks/bookkeeping.py` verifies exactly, at $q = 4$, the shares $s - a_x$ and the prefactor $q/|\det(J - I)| = 1$.

Corollary 26.10 (Series-parallel tables at their full leans). *As stated, with any weights on the bases of the series and parallel nodes.*

Proof. By Theorem 26.5 the period of $\mathcal{B}$ at its full basis lean is the product over the nodes of their periods at their node loads over the Beta corners $\Gamma_{\substack{2\\1}}\begin{bmatrix}k_{v,\mathfrak{e}}, & k_{w,\mathfrak{e}}\\ & s\end{bmatrix}$ of the edges, the weights of $\mathcal{B}$ being the products of those of the nodes (Definition 26.2). Proposition 26.9 gives each node: $\Gamma_{\substack{n_v\\1}}\begin{bmatrix}(s-(\mathbf{a}_v)_x)_x\\ s\end{bmatrix} \prod_x \theta_{v,x}^{(\mathbf{a}_v)_x - s}$ at a series node and $\Gamma_{\substack{n_v\\1}}\begin{bmatrix}((\mathbf{a}_v)_x)_x\\ s\end{bmatrix} \prod_x \theta_{v,x}^{-(\mathbf{a}_v)_x}$ at a parallel node, $n_v = |\mathcal{E}_v| + |G_v|$. The Gammas, the factors $\Gamma(s)$ and the corners combine as in the reference, proof of cor:spfulllean: a tree has one node more than edges, which leaves $1/\Gamma(s)$; a mark e contributes $\Gamma(s - a_e)$ at a series node and $\Gamma(a_e)$ at a parallel node; at an edge $\mathfrak{e} = \{v, w\}$, where $k_{v,\mathfrak{e}} + k_{w,\mathfrak{e}} = s$ (Lemma 26.4(i)), the two markers contribute $\Gamma(s - k_{v,\mathfrak{e}})\Gamma(s - k_{w,\mathfrak{e}}) = \Gamma(k_{w,\mathfrak{e}})\Gamma(k_{v,\mathfrak{e}})$ between two series nodes and $\Gamma(k_{v,\mathfrak{e}})\Gamma(k_{w,\mathfrak{e}})$ between two parallel nodes, which the corner cancels, and $\Gamma(s - k_{v,\mathfrak{e}})\Gamma(k_{w,\mathfrak{e}})$ when v is a series and w a parallel node, which the corner leaves as $\Gamma(s - k_{\mathfrak{e}})/\Gamma(k_{\mathfrak{e}})$, $k_{\mathfrak{e}} = k_{v,\mathfrak{e}}$. The monomials of the nodes stand as they are. The full cobasis lean is the same with the second pair of forms of Proposition 26.9: $\Gamma(b_e)$ at series and $\Gamma(t - b_e)$ at parallel nodes, and at

an edge with the series end v the quotient $\Gamma(l_{v,\mathfrak{e}})\Gamma(t-l_{w,\mathfrak{e}})/\big(\Gamma(l_{v,\mathfrak{e}})\Gamma(l_{w,\mathfrak{e}})\big)=\Gamma(l_{\mathfrak{e}})/\Gamma(t-l_{\mathfrak{e}})$. The criterion of finiteness does not see the weights, which enter through monomials, positive and finite at real loads; it is the reference's. □

Corollary 26.11 (Periods along a hinge tree read by one hinge value). *As stated: for a family whose tables have a common hinge tree, at real data, wherever the active letters read every subtree cell by one hinge value.*

Proof. Induction on the number of edges of $\mathfrak{T}$. With one vertex there is nothing to prove.

Removing a leaf. A tree with an edge has two leaves, so some leaf v differs from o; let p be its parent and $\mathfrak{e}=\mathfrak{e}_v$. The subtree cell $\mathcal{A}_{v,j}$ is the node $\mathcal{H}_{v,j}$ with the hinge $g_{v,\mathfrak{e}}$ (23.15). The two-sums along a tree may be taken in any order (23.5, 21.3(i),(ii)), so table j of F is the substitution $\mathcal{H}'_j\langle\mathcal{A}_{v,j}\rangle$ of the cell $\mathcal{A}_{v,j}$ at the mark $g_{p,\mathfrak{e}}$ of the table $\mathcal{H}'_j$ obtained from the other nodes along $\mathfrak{T}-v$, every other mark of $\mathcal{H}'_j$ left in place. The cell on $\mathcal{E}_v$ is read by the active letters through γ_v, and a mark left in place through α_h, so 22.6 applies; the factors of the marks left in place cancel (its step (5)), and with $\kappa_{\mathfrak{e}}=\kappa_{\mathcal{E}_v}$,

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t})\,\Gamma_{\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\begin{bmatrix}\kappa_{\mathfrak{e}}, & 2\sigma-\kappa_{\mathfrak{e}}\\ & 2\sigma\end{bmatrix}=P_{F'}(\mathbf{m}';\mathbf{s},\mathbf{t})\,P_{F_{\mathcal{H}_v}}(\mathbf{m}_v;\mathbf{s},\mathbf{t}),$$

F' the family of the tables $\mathcal{H}'_j$ at the masses $\mathbf{m}'$ equal to $\mathbf{m}$ on its marks and to $\kappa_{\mathcal{E}_v}$ at $g_{p,\mathfrak{e}}$, and $\mathbf{m}_v$ equal to $\mathbf{m}|_{\mathcal{E}_v}$ and to $2\sigma-\kappa_{\mathcal{E}_v}=\kappa_{\mathcal{E}\setminus\mathcal{E}_v}$ at $g_{v,\mathfrak{e}}$; every factor is on its balance wall with every proper wall positive.

The walls of F'. By 21.10, a set S' of marks of F' containing $g_{p,\mathfrak{e}}$ has the wall of $(S'\setminus\{g_{p,\mathfrak{e}}\})\sqcup\mathcal{E}_v$ in F, the cell entering with its whole set $\mathcal{E}_v$, of wall $\kappa_{\mathcal{E}_v}$, and the marker in D_j and D_j^*; a set avoiding $g_{p,\mathfrak{e}}$ has the same wall in both. So the walls across the edges of $\mathfrak{T}-v$ are those of F.

The hypothesis passes to F'. F' has the common hinge tree $\mathfrak{T}-v$, with the same nodes and $g_{p,\mathfrak{e}}$ a mark of the node p. Its subtree cells are those of F except at the vertices w on the path from p to o, where $\mathcal{A}_{w,j}=\mathcal{A}'_{w,j}\langle\mathcal{A}_{v,j}\rangle$, the cell at the mark $g_{p,\mathfrak{e}}$ (21.3(ii)). By 21.4 the hinge minors of $\mathcal{A}_{w,j}$ are those of $\mathcal{A}'_{w,j}$ with $\alpha_{g_{p,\mathfrak{e}}}$ replaced by $\gamma^K_{\mathcal{A}_{v,j}}$ in the letters K and by $\gamma^\Psi_{\mathcal{A}_{v,j}}$ in the letters Ψ, times factors of $\mathcal{A}_{v,j}$ that cancel in the quotients, so

$$\gamma^K_{\mathcal{A}_{w,j}}(\alpha)=\gamma^K_{\mathcal{A}'_{w,j}}\big(\alpha',\gamma^K_{\mathcal{A}_{v,j}}(\alpha_{\mathcal{E}_v})\big),\qquad \gamma^\Psi_{\mathcal{A}_{w,j}}(\alpha)=\gamma^\Psi_{\mathcal{A}'_{w,j}}\big(\alpha',\gamma^\Psi_{\mathcal{A}_{v,j}}(\alpha_{\mathcal{E}_v})\big),$$

α' the variables of the other marks. For the active letters both inner hinge values are $\gamma_v(\alpha_{\mathcal{E}_v})$, and γ_v, positive and homogeneous of degree one, takes every value in $(0,\infty)$. So for every value $c>0$ at $g_{p,\mathfrak{e}}$ the hinge values of $\mathcal{A}'_{w,j}$ by the active letters at (α',c) all equal $\gamma_w(\alpha)$ for any α with $\gamma_v(\alpha_{\mathcal{E}_v})=c$: the active letters read $\mathcal{A}'_{w,j}$ by one hinge value, and the induction hypothesis applies to F'. Its product formula and the display give that of F, with the masses on the markers the walls across the edges.

One table at a full lean. One letter is active, and the hypothesis is empty. At $(s,0)$ on the balance wall $|\mathbf{m}|=rs$, so the loads $\mathbf{a}=\mathbf{m}$ are admissible in 26.5; the marker load $k_{v,\mathfrak{e}}=sr_v^{\mathfrak{e}}-m_{\mathcal{E}_v^{\mathfrak{e}}}$ is $s-\kappa_{\mathcal{E}_v^{\mathfrak{e}}}$, the wall of the branch at v being $m_{\mathcal{E}_v^{\mathfrak{e}}}-s(r_v^{\mathfrak{e}}-1)$, and the two walls across an edge add to s; so the node loads are the masses $\mathbf{m}_v$ and the two identities are the same (26.4). At $(0,t)$ the same holds with $\mathbf{b}$ and t. The series and parallel nodes are 26.9.

Tables glued along a tree. The glued table has the hinge tree whose nodes are the tables $\mathcal{A}_v$ and whose markers are the glued marks; the glued marks of connected tables are neither loops nor coloops, and a two-sum has the product weights (21.12). The masses of the glued marks are positive, every singleton being a proper wall of its table, so every $\kappa_{\mathfrak{e}}$ lies in $(0,t)$. Each table

$\mathcal{A}_v$ is balanced, $m_{\mathcal{E}_{\mathcal{A}_v}} = tr^*_{\mathcal{A}_v}$, and the glued table, of corank $\sum_v r^*_{\mathcal{A}_v} - (k-1)$ and total mass $\sum_v tr^*_{\mathcal{A}_v} - (k-1)t$, is on its balance wall. Removing a leaf as above, with the first display of 22.6 in $[0,\infty]$ and its step (2), the cell at a leaf v glued along its mark g has the wall $t - m_g$ and its cell family is $\mathcal{A}_v$ at its own masses, so the period of the glued table is $\prod_v P_{\mathcal{A}_v} / \prod_{\mathfrak{e}} \Gamma_{\substack{2\\1}}\!\left[\begin{smallmatrix}\kappa_{\mathfrak{e}},\ t-\kappa_{\mathfrak{e}}\\ t\end{smallmatrix}\right]$ in $[0,\infty]$; it is finite, and the glued table, balanced, has every proper wall positive (8.7).

A chain. By 21.12 the chain $F^{\triangleright k}$ of 22.8 has the hinge tree whose nodes are the copies, a path, the glued marks its markers; by the propagation of the hypothesis above, its subtree cells are read by the active letters through one hinge value when the copy is, and the walls across its edges are $m_{g_{\mathrm{in}}}$ and $m_{g_{\mathrm{out}}}$, so with every proper wall positive the display gives the product $P_F^k / \Gamma_{\substack{2\\1}}\!\left[\begin{smallmatrix}m_{g_{\mathrm{in}}},\ m_{g_{\mathrm{out}}}\\ 2\sigma\end{smallmatrix}\right]^{k-1}$. □

Theorem 26.12 (Blocks read by one hinge value aggregate exactly). *As stated: in (ii) blocks read through $e_\ell/e_{\ell-1}$ as well as blocks read through their totals, and the active letters at nonzero exponents of either sign.*

Proof. (i) and (iii). These are the reference proof of 26.12(i),(iii), the letters with positive exponent replaced by the active letters: at a parallel block $K_{\mathcal{A}/g} = 1$ and $\gamma^K_{\mathcal{A}} = e_1$, at a series block $\Psi_{\mathcal{A}\setminus g} = 1$ and $\gamma^\Psi_{\mathcal{A}} = e_1$ (21.7(i)), so by 21.4 every active letter is the letter of its core read at the block totals, and the totals of $U \sim \mathrm{Dir}_{\mathbf{m}}$ have the law $\mathrm{Dir}_{(m_{B_i})_i}$ (3.10). The sign of an exponent does not enter.

(ii). When a block has $\ell_i \geq 2$ marks a table with both letters active would need a block that is both parallel and series; so at such a block each table has at most one active letter, and the inactive letters, of exponent 0, enter neither the walls nor the kernels. By 21.7(i), for $i \in I$ the active hinge values are $\gamma^K = e_1$ at the parallel blocks and $\gamma^\Psi = e_1$ at the series blocks, and for $i \notin I$ they are $\gamma^K = e_{\ell_i}/e_{\ell_i-1}$ at the series blocks and $\gamma^\Psi = e_{\ell_i}/e_{\ell_i-1}$ at the parallel blocks. So 22.5 applies with all constants 1 and $\gamma_i = e_1$ for $i \in I$, $\gamma_i = e_{\ell_i}/e_{\ell_i-1}$ for $i \notin I$:

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t}) = P_{F_{\mathcal{H}}}\big((\kappa_{B_i})_i;\mathbf{s},\mathbf{t}\big)\prod_i S_i, \qquad S_i = \int_{\Delta_{B_i}} \gamma_i^{-\kappa_{B_i}}\, d\beta_i,$$

in $[0,\infty]$. By 21.10, $\kappa_{B_i} = m_{B_i} - \sum_j \big(s_j(r_{\mathcal{A}_{ij}} - 1) + t_j(\ell_i - r_{\mathcal{A}_{ij}})\big)$ with the ranks 1 of a parallel block and ℓ_i of a series block.

For $i \in I$ the active letters see ranks that make every term vanish, so $\kappa_{B_i} = m_{B_i}$; the density of the cell kernel is $u^{\mathbf{m}|_{B_i}-\mathbf{1}}$, the active minors $K_{\mathcal{A}/g}$ and $\Psi_{\mathcal{A}\setminus g}$ being 1; and $e_1 = 1$ on the simplex, so $S_i = \int_{\Delta_{B_i}} u^{\mathbf{m}|_{B_i}-\mathbf{1}} d\omega$, which is $\Gamma_{\substack{\ell_i\\1}}\!\left[\begin{smallmatrix}\mathbf{m}|_{B_i}\\ m_{B_i}\end{smallmatrix}\right]$ when every m_x is positive and $+\infty$ otherwise, by the shape integral (3.11).

For $i \notin I$ each active letter contributes its exponent times $\ell_i - 1$, so $\kappa_{B_i} = m_{B_i} - (\ell_i - 1)2\sigma$. The active minors are $K_{\mathcal{A}/g} = e_{\ell_i-1}$ at a series block and $\Psi_{\mathcal{A}\setminus g} = e_{\ell_i-1}$ at a parallel block, so the density of the cell kernel is $u^{\mathbf{m}|_{B_i}-\mathbf{1}} e_{\ell_i-1}(u)^{-2\sigma}$, and with $e_{\ell_i} = \prod_{x\in B_i} u_x$,

$$S_i = \int_{\Delta_{B_i}} \Big(\frac{e_{\ell_i}}{e_{\ell_i-1}}\Big)^{-\kappa_{B_i}} u^{\mathbf{m}|_{B_i}-\mathbf{1}} e_{\ell_i-1}^{-2\sigma}\, d\omega = \int_{\Delta_{B_i}} u^{\mathbf{m}|_{B_i}-\kappa_{B_i}\mathbf{1}-\mathbf{1}}\, e_{\ell_i-1}(u)^{-(2\sigma-\kappa_{B_i})}\, d\omega.$$

This is the period of the series node $\binom{B_i}{\ell_i-1}$ with unit weights, whose letter K is e_{ℓ_i-1}, at the full basis lean $(2\sigma-\kappa_{B_i},0)$ and the masses $m_x - \kappa_{B_i}$; they add to $m_{B_i} - \ell_i\kappa_{B_i} = (\ell_i-1)(2\sigma-\kappa_{B_i})$, its balance wall. By 26.9 it is $\Gamma_{\substack{\ell_i\\1}}\!\left[\begin{smallmatrix}(2\sigma-\kappa_{B_i}-m_x+\kappa_{B_i})_x\\ 2\sigma-\kappa_{B_i}\end{smallmatrix}\right] = \Gamma_{\substack{\ell_i\\1}}\!\left[\begin{smallmatrix}(2\sigma-m_x)_x\\ 2\sigma-\kappa_{B_i}\end{smallmatrix}\right]$, convergent exactly

when every $2\sigma - m_x$ is positive, and $+\infty$ otherwise, the integrand being positive. At $\ell_i = 1$ both kinds give $\kappa_{B_i} = m_x$ and $S_i = 1$.

So the display holds in $[0, \infty]$ with the stated reading of the stacked Gammas, and when these are finite the two sides are finite together.

The last sentence. At $\ell \geq 2$ the functions e_1 and $e_\ell / e_{\ell-1}$ are not proportional on the simplex, their quotient $e_1 e_{\ell-1}/e_\ell = (\sum_x u_x)(\sum_x u_x^{-1})$ being unbounded; so 22.5 does not apply to a block read both ways, and 22.3 keeps it as one mark with its kernel and both hinge values. □

Remark. Checks 7a to 7d of S21-23_work/checks.py are the case $\ell = 2$ of the blocks with $i \notin I$, with one table at $(s_1, 0)$ and one at $(0, t_2)$: $S = \Gamma(2\sigma - m_1)\Gamma(2\sigma - m_2)/\Gamma(4\sigma - m_B)$, and the period of the cell family is $\Gamma_{\substack{2\\1}}\begin{bmatrix}\kappa, & 2\sigma - \kappa \\ & 2\sigma\end{bmatrix} S$.

Theorem 26.13 (The network). *As stated, for every family.*

Proof. Every table is one molecule by Lemma 26.1 along its hinge tree, and every proper wall is positive, so Theorem 25.12(ii) writes $P_{F[\mathbf{x}]}$ as the fibre integral of $\prod_j P_{\mathcal{B}_j}(\mathbf{a}_j; s_j, 0) P_{\mathcal{B}_j}(\mathbf{b}_j; 0, t_j)$ times the twists, on the imaginary translate through an admissible point $\mathbf{c}$. At $\mathbf{c}$ every $P_{\mathcal{B}_j}(\mathbf{c}_j^K; s_j, 0)$ and $P_{\mathcal{B}_j}(\mathbf{c}_j^\Psi; 0, t_j)$ is finite (Proposition 25.10(ii)), so by Theorem 26.5 in table j every marker load lies in $(0, s_j)$, respectively $(0, t_j)$, every node period is finite at its node loads, and both factorizations of Theorem 26.5 hold on the tube over these real loads, which contains the translate. Inserting them gives the integrand of the statement. The native loads are admissible by Proposition 25.10(iii). The node periods are functions of the node loads alone, the exponent of the one active letter of a node being its total load divided by its degree (Definition 25.9). □

Corollary 26.14 (Series-parallel periods). *As stated, for every family and any weights on the bases of the nodes.*

Proof. Insert Corollary 26.10 for both full leans of every table into Theorem 26.13 and multiply by $\prod_j \Gamma(s_j)\Gamma(t_j)$. At a series node the monomials of the two leans multiply to $\theta_{j,v,x}^{(\mathbf{a}_{j,v})_x - s_j} \theta_{j,v,x}^{-(\mathbf{b}_{j,v})_x}$, at a parallel node to $\theta_{j,v,x}^{-(\mathbf{a}_{j,v})_x} \theta_{j,v,x}^{(\mathbf{b}_{j,v})_x - t_j}$. At a real point at which every Gamma above the line has an argument of positive real part all the periods of the tables at their full leans are finite (Corollary 26.10), so the point is admissible (Proposition 25.10(ii)) and Theorem 26.13 applies on it. The dimension is that of Theorem 26.13, and the integrand does not involve the bases of the tables. □

Proposition 26.15 (Pooling a pair). *As stated, with any weights on the bases of the node.*

Proof. For one table the pins are $\mathbf{a} + \mathbf{b} = \mathbf{m}$ and $|\mathbf{b}| = r^* t$, the twist $\mathbf{x}$ is on the cobasis letter, and the integrand of Corollary 26.14 is a function of $\mathbf{b}$, with $\Gamma(s - a_e) = \Gamma(c_e + b_e)$ at a mark e of a series node. The marks e and f of one node v lie on one side of every edge, so every marker load, an affine function of sums of loads over branches (Definition 26.3), depends on b_e and b_f through $b_{\{e,f\}}$ alone; so do the Gammas of the other marks, the monomials of the other nodes and those of the markers of v. What is left at a series node is $\Gamma(c_e + b_e)\Gamma(b_e)\Gamma(c_f + b_f)\Gamma(b_f)$ times

$$\theta_{v,e}^{a_e - b_e - s} \theta_{v,f}^{a_f - b_f - s} x_e^{-b_e} x_f^{-b_f} = \theta_{v,e}^{m_e - s} \theta_{v,f}^{m_f - s} \left(x_e \theta_{v,e}^2\right)^{-b_e} \left(x_f \theta_{v,f}^2\right)^{-b_f},$$

a function of $b_{\{e,f\}}$ when $x_e \theta_{v,e}^2 = x_f \theta_{v,f}^2$; at a parallel node it is $\Gamma(m_e - b_e)\Gamma(t - b_e)\Gamma(m_f - b_f)\Gamma(t - b_f)$ times $\theta_{v,e}^{-m_e - t} \theta_{v,f}^{-m_f - t} \left(x_e \theta_{v,e}^{-2}\right)^{-b_e} \left(x_f \theta_{v,f}^{-2}\right)^{-b_f}$, from the monomials $\theta_{v,x}^{b_x - a_x - t}$, a function of $b_{\{e,f\}}$ when

$x_e\theta_{v,e}^{-2} = x_f\theta_{v,f}^{-2}$. The rest is the reference, proof of prop:poolpair, with $x_e\theta_{v,e}^{\pm 2}$ in place of x_e: at fixed $b_{\{e,f\}}$ the integral over b_e is the integral of four Gammas displayed in the statement, and disjoint pairs occupy disjoint coordinates. □

Theorem 26.16 (Nodes in hold form). *As stated, for every substituted family.*

Proof. The cores $\mathcal{H}_j$ and the cells $\mathcal{A}_{ij}$ are molecules by Lemma 26.1, and the markers are neither loops nor coloops of their cores and cells. Table j carries the hinge tree whose nodes are $\mathcal{H}_j$ and the $\mathcal{A}_{ij}$, each cell read as a core on $B_i \sqcup \{g_i\}$ and joined to $\mathcal{H}_j$ by an edge $\mathfrak{e}_i$ (Definition 23.15), the table being obtained by these two-sums (Proposition 21.3(i)). Each B_i is nonempty, a hinge being neither a loop nor a coloop; fix $e_i \in B_i$.

(i) *Step 1: the network.* Let $\mathbf{c}$ be an admissible point of F. By Theorem 26.13 with these trees, $P_{F[\mathbf{x}]}(\mathbf{m};\mathbf{s},\mathbf{t})$ is the fibre integral, over the loads of F with the pins $\sum_j(\mathbf{a}_j+\mathbf{b}_j)=\mathbf{m}$, $|\mathbf{a}_j| = r_j s_j$ ($j \geq 2$) and $|\mathbf{b}_j| = r_j^* t_j$, on the translate through $\mathbf{c}$, of

$$\prod_j \frac{P_{\mathcal{H}_j}(\mathbf{a}_{j,\mathcal{H}};s_j,0)P_{\mathcal{H}_j}(\mathbf{b}_{j,\mathcal{H}};0,t_j)\prod_i P_{\mathcal{A}_{ij}}(\mathbf{a}_{j,i};s_j,0)P_{\mathcal{A}_{ij}}(\mathbf{b}_{j,i};0,t_j)}{\prod_i \Gamma_1^2\begin{bmatrix} a_{j,g_i},\ s_j-a_{j,g_i} \\ s_j\end{bmatrix}\Gamma_1^2\begin{bmatrix} b_{j,g_i},\ t_j-b_{j,g_i} \\ t_j\end{bmatrix}} (\mathbf{x}_j^K)^{-\mathbf{a}_j|\varepsilon_{\mathcal{H}}}(\mathbf{x}_j^\Psi)^{-\mathbf{b}_j|\varepsilon_{\mathcal{H}}}.$$

Here, by Definition 26.3 with the branch B_i on the side of the cell, of rank $r_{\mathcal{A}_{ij}}$ and corank $|B_i|+1-r_{\mathcal{A}_{ij}}$, and by Lemma 26.4(i), the marker loads of the core at g_i are

$$a_{j,g_i} = a_{j,B_i} - s_j\big(r_{\mathcal{A}_{ij}}-1\big), \qquad b_{j,g_i} = b_{j,B_i} - t_j\big(|B_i|-r_{\mathcal{A}_{ij}}\big),$$

those of the cell at g_i are $s_j - a_{j,g_i}$ and $t_j - b_{j,g_i}$, the node loads of the core are $\mathbf{a}_{j,\mathcal{H}} = (\mathbf{a}_j|_{\mathcal{E}_{\mathcal{H}}}, (a_{j,g_i})_i)$ and $\mathbf{b}_{j,\mathcal{H}} = (\mathbf{b}_j|_{\mathcal{E}_{\mathcal{H}}}, (b_{j,g_i})_i)$, and those of the cell $\mathcal{A}_{ij}$ are $\mathbf{a}_{j,i} = (\mathbf{a}_j|_{B_i}, s_j - a_{j,g_i})$ and $\mathbf{b}_{j,i} = (\mathbf{b}_j|_{B_i}, t_j - b_{j,g_i})$. The twists are 1 off $\mathcal{E}_{\mathcal{H}}$.

Step 2: the marker loads as coordinates. In every table j and for every i replace the coordinate a_{j,e_i} by a_{j,g_i} and b_{j,e_i} by b_{j,g_i}. Each new coordinate is the old one plus other old coordinates plus a constant, so the change of coordinates is unit triangular, of determinant 1, and by Lemma S11(i) the fibre integral does not change. The new coordinates are the *core coordinates*, the loads $(\mathbf{a}_{j,\mathcal{H}}, \mathbf{b}_{j,\mathcal{H}})_j$ of the cores on $\mathcal{E}_{\mathcal{H}} \sqcup \{g_1,\dots,g_k\}$, and for each i the *coordinates of* B_i, the loads $a_{j,e}$ and $b_{j,e}$ at the marks $e \in B_i \setminus e_i$, $j = 1,\dots,N$.

Step 3: the core masses. Replace the mass pin at e_i by the sum C_i of the mass pins over B_i, a row operation with the coefficient 1 on the replaced pin, of determinant 1 (Lemma S11(i)). In the new coordinates

$$C_i: \qquad \sum_j \big(a_{j,g_i}+b_{j,g_i}\big) = m_{B_i} - \sum_j \Big(s_j\big(r_{\mathcal{A}_{ij}}-1\big) + t_j\big(|B_i|-r_{\mathcal{A}_{ij}}\big)\Big) = \kappa_{F_i}$$

by Definition 23.1: the mass of the cores at g_i is the hinge wall of the cell family at g_i.

Step 4: the totals, and the split of the pins. By Proposition 21.3(i), $r_j = r_{\mathcal{H}_j} + \sum_i (r_{\mathcal{A}_{ij}}-1)$, and so $r_j^* = n - r_j = r_{\mathcal{H}_j}^* + \sum_i(|B_i| - r_{\mathcal{A}_{ij}})$ with $r_{\mathcal{H}_j}^* = |\mathcal{E}_{\mathcal{H}}| + k - r_{\mathcal{H}_j}$ and $n = |\mathcal{E}_{\mathcal{H}}| + \sum_i |B_i|$. In the new coordinates therefore

$$|\mathbf{a}_j| = \big|\mathbf{a}_j|_{\mathcal{E}_{\mathcal{H}}}\big| + \sum_i \Big(a_{j,g_i} + s_j\big(r_{\mathcal{A}_{ij}}-1\big)\Big), \qquad \text{so} \qquad |\mathbf{a}_j| = r_j s_j \iff |\mathbf{a}_{j,\mathcal{H}}| = r_{\mathcal{H}_j} s_j,$$

and likewise $|\mathbf{b}_j| = r_j^* t_j \iff |\mathbf{b}_{j,\mathcal{H}}| = r_{\mathcal{H}_j}^* t_j$. The pins are now the *core pins*, namely the mass pins at $\mathcal{E}_{\mathcal{H}}$, the C_i and the totals of the cores, on the core coordinates alone, which are the pins of

$\mathcal{F}$; and for each i the *pins of* B_i, the mass pins at $e \in B_i \setminus e_i$, on the coordinates of B_i alone. The pin matrix is block diagonal, and since the fibre integral converges absolutely (Theorem 25.12(ii)), Lemma S11(iii) writes it as the integral over $\mathcal{F}$, on the translate through the core node loads of $\mathbf{c}$, of the fibre integrals over the coordinates of the B_i at fixed core coordinates. The corners and the twists depend on the core coordinates alone and leave the inner integrals, and the inner integral for B_i is

$$\Phi_i = \int \prod_j P_{\mathcal{A}_{ij}}(\mathbf{a}_{j,i}; s_j, 0)\, P_{\mathcal{A}_{ij}}(\mathbf{b}_{j,i}; 0, t_j)$$

over the coordinates of B_i with the pins of B_i.

Step 5: the inner integrals are holds. Let $F_i^\natural$ be the family of the tables $\mathcal{A}_{ij}$ on $B_i \sqcup \{g_i\}$ with the masses $\mathbf{m}|_{B_i}$ and $\sum_j (s_j + t_j) - \kappa_{F_i}$ on g_i, on its balance wall (Lemma 21.12). The node loads $(\mathbf{a}_{j,i}, \mathbf{b}_{j,i})_j$ of the cells are loads of its letters: for every j, $|\mathbf{a}_{j,i}| = a_{j,B_i} + s_j - a_{j,g_i} = r_{\mathcal{A}_{ij}} s_j$ and $|\mathbf{b}_{j,i}| = t_j(|B_i| + 1 - r_{\mathcal{A}_{ij}})$, their masses at $e \in B_i$ are the m_e, and at g_i they add to $\sum_j (s_j + t_j - a_{j,g_i} - b_{j,g_i}) = \sum_j (s_j + t_j) - \kappa_{F_i}$ by C_i. At $\mathbf{c}$ every period of a cell at its node loads is finite (Theorem 26.5), so the node loads of the cells at $\mathbf{c}$ are an admissible point of $F_i^\natural$ (Proposition 25.10(ii)), and every proper wall of $F_i^\natural$ is positive (Theorem 25.12(i)). In Theorem 25.14 for $F_i^\natural$ take e_i as the fixed mark and $G = \{g_i\}$: the pinned fibre integral at the pins $s_j - a_{j,g_i}$ $(j \geq 2)$ and $t_j - b_{j,g_i}$ at g_i is, in the coordinates of the loads of the letters other than K_1 at the marks of $B_i \setminus e_i$, the integral with the factor $(2\pi i)^{-(2N-1)(|B_i|-1)}$, the other loads solved from its pins. The integral Φ_i, with $a_{1,e}$ for $e \in B_i \setminus e_i$ solved from the mass pin at e, has the same coordinates, the same factor by Lemma S11(ii), and the same integrand, since the loads $(\mathbf{a}_{j,i}, \mathbf{b}_{j,i})_j$ satisfy all the pins of $F_i^\natural$. The real parts of the core coordinates being those of $\mathbf{c}$, Theorem 25.14 gives

$$\Phi_i = \mathrm{Hold}_{\{g_i\}}\big((s_j - a_{j,g_i})_{j\geq 2}, (t_j - b_{j,g_i})_j\big) \qquad \text{for } F_i^\natural.$$

Step 6: the corners cancel. Apply Lemma 25.16 to the cell family F_i at $\mathbf{z}_i = (a_{j,g_i}, b_{j,g_i})_j$, of sum κ_{F_i} by C_i. Its conditions hold: $0 < \mathrm{Re}\, a_{j,g_i} < s_j$ and $0 < \mathrm{Re}\, b_{j,g_i} < t_j$, the marker loads at $\mathbf{c}$ lying in these intervals (Theorem 26.5); and the hold of Step 5 at the real parts is finite, so by Proposition 25.15 and the first identity of Lemma 25.16 $\int \boldsymbol{\varrho}_{F_i}^{-\mathrm{Re}\,\mathbf{z}_i} d\phi_{F_i}$ is finite. So

$$\Phi_i = \prod_j \Gamma_1^2\begin{bmatrix} s_j - a_{j,g_i}, & a_{j,g_i} \\ & s_j \end{bmatrix} \Gamma_1^2\begin{bmatrix} t_j - b_{j,g_i}, & b_{j,g_i} \\ & t_j \end{bmatrix} \int \boldsymbol{\varrho}_{F_i}^{-\mathbf{z}_i} d\phi_{F_i},$$

and these are the corners of the edge $\mathfrak{e}_i$ in Step 1, $\Gamma_1^2\begin{bmatrix} a, & b \\ & a+b \end{bmatrix}$ being symmetric in a and b. They cancel, and what is left is the integral of (i) over $\mathcal{F}$. Its dimension is the number $2N(|\mathcal{E}_\mathcal{H}| + k)$ of core coordinates less the $|\mathcal{E}_\mathcal{H}| + k + 2N - 1$ core pins, $(2N-1)(|\mathcal{E}_\mathcal{H}| + k - 1)$.

(ii) Let $F'^\natural$ be the family of the tables of F' with the mass $\sum_j (s_j + t_j) - \kappa_{F'}$ on g_0, on its balance wall (Lemma 21.12), and $\mathbf{c}$ an admissible point of it as in the statement. Its loads at g_0 lie in $(0, s_j)$ and $(0, t_j)$, g_0 being neither a loop nor a coloop, so $\mathrm{Re}\,\mathbf{z}$ meets the conditions of Lemma 25.16 for F'; the finiteness of $\int \boldsymbol{\varrho}_{F'}^{-\mathrm{Re}\,\mathbf{z}} d\phi_{F'}$ follows as in Step 6 from that of the hold of $F'^\natural$ at g_0 at the loads of $\mathbf{c}$ (Theorem 25.14). By the second identity of Lemma 25.16 the left side of (ii) is the hold of $F'^\natural$ at g_0 at the loads $(s_j - z_{j,K})_{j\geq 2}$ and $(t_j - z_{j,\Psi})_j$, and by Theorem 25.14 with $G = \{g_0\}$ it is the fibre integral of Theorem 25.12(ii) for $F'^\natural$ at $\mathbf{x} = \mathbf{1}$ with the pins at g_0. Steps 1 to 6 apply to it with g_0 a mark of the cores, its pins being core pins, and give the integral over $\mathcal{F}_\mathbf{z}$, of dimension $(2N-1)(|\mathcal{E}_\mathcal{H}| + k) - (2N-1) = (2N-1)(|\mathcal{E}_\mathcal{H}| + k - 1)$. □

Remark. Let the core of every table be $\binom{\{g_1,g_2\}}{1}$ with unit weights, the weights of the tables being those of the cells (Lemma 21.12), so that $\mathcal{E}_{\mathcal{H}} = \varnothing$ and $B = B_1$ is a bunch of width one in every table. By Proposition 26.9 at $q = 1$,

$$P_{\mathcal{H}_j}(\mathbf{a}_{j,\mathcal{H}}; s_j, 0)\, P_{\mathcal{H}_j}(\mathbf{b}_{j,\mathcal{H}}; 0, t_j) = \Gamma_{\!\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\begin{bmatrix} a_{j,g_1},\ a_{j,g_2} \\ s_j \end{bmatrix} \Gamma_{\!\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\begin{bmatrix} b_{j,g_2},\ b_{j,g_1} \\ t_j \end{bmatrix} = \Gamma_{\!\!\begin{smallmatrix}4\\2\end{smallmatrix}}\!\begin{bmatrix} a_j^d,\ b_j^d,\ a_j^r,\ b_j^r \\ s_j,\ t_j \end{bmatrix}$$

of Theorem 19.13, with the level shares $a_j^r = a_{j,g_1}$, $a_j^d = a_{j,g_2}$, $b_j^d = b_{j,g_1}$ and $b_j^r = b_{j,g_2}$. With $\mathbf{z}_1 = (a_j^r, b_j^d)_j$ the children family of F_1 in Lemma 25.16 has the tables $\mathcal{A}_{1j} \setminus g_1 = \mathcal{B}_j | B$ at $(a_j^r, t_j - b_j^d) = (a_j^r, b_j^r)$ and $\mathcal{A}_{1j}/g_1 = \mathcal{B}_j/R$ at $(s_j - a_j^r, b_j^d) = (a_j^d, b_j^d)$: it is the bunch family of Theorem 19.13; with $\mathbf{z}_2 = (a_j^d, b_j^r)_j$ the children family of F_2 is the room family. The core pins are $|\mathbf{a}_{j,\mathcal{H}}| = s_j$ $(j \geq 2)$, $|\mathbf{b}_{j,\mathcal{H}}| = t_j$ and the masses κ_{F_1} and κ_{F_2}; solving the totals for a_j^d and b_j^r by Lemma S11(ii), with the block of the totals and of the mass κ_{F_2} unit triangular after the row operations of Lemma S11(i), leaves the share integral over $(a_j^r, b_j^d)_j$ pinned by $\sum_j (a_j^r + b_j^d) = \kappa_{F_1} = \kappa_B$. This is the integral of Theorem 19.13 over the scale shares, with the same integrand. In the pair coordinates $\sigma_j^d = \frac{1}{2}(a_j^d + b_j^d)$ and $\delta_j^d = \frac{1}{2}(a_j^d - b_j^d)$, the map $(a_j^r, b_j^d) \mapsto (\sigma_j^d, \delta_j^d)$, with $a_j^d = s_j - a_j^r$, has the determinant $\frac{1}{2}$ in each table, so $d(\mathbf{a}^r, \mathbf{b}^d) = 2^N\, d(\boldsymbol{\sigma}^d, \boldsymbol{\delta}^d)$; and the pin $\sum_j (a_j^r + b_j^d) = \kappa_B$ reads $-2\sum_j \delta_j^d = \kappa_B - \sum_j s_j$, its row being -2 times that of $\sum_j \delta_j^d = \frac{1}{2}(\sum_j s_j - \kappa_B)$, which by Definition 4.1 multiplies the fibre measure by $\frac{1}{2}$. The two factors give the 2^{N-1} of the first display of Theorem 19.13, a consistency check of the bookkeeping above. In `checks/bookkeeping.py`, `check_twosides_pairs` computes $2^N \cdot \frac{1}{2} - 2^{N-1} = 0$ exactly; `check_core_family_balance` computes the balance of the core family at the masses $(\mathbf{m}|_{\mathcal{E}_{\mathcal{H}}}, \kappa_{F_1}, \ldots, \kappa_{F_k})$ and the corank identity of Step 4; and `check_holdnode_pins` computes, for small families, the unit Jacobian of Step 2, the split of the pins of Steps 3 and 4 with the core masses κ_{F_i} and the totals of the cores, and the totals and the hinge mass of the node loads of the cells in Step 5.

Corollary 26.17 (The glue and the series and parallel rules in hold form). *As stated; in (i) the reading for a family is new.*

Proof. For one table the point $\mathbf{z}_i$ of Theorem 26.16 is $(\kappa_{\mathcal{A}_i} - b_{g_i}, b_{g_i})$, by the core mass at g_i, and $\boldsymbol{\varrho}_{F_i}^{-\mathbf{z}_i} = \varrho_{\mathcal{A}_i}^{-b_{g_i}}$, the ratio vector of one cell being its ratio (Definition 23.1); so (i) for one table, (ii) and (iii) are the reference, proof of cor:holdrules. The reading of (i) for a family is the remark after the proof of Theorem 26.16. □

Definition 26.18 (The network procedure). As stated, for a family whose tables carry hinge trees; pooling and the passage to the transforms are for one table, and the recursive Mellin evaluation asks the tables to share one rooted tree.

Remark. The operations rest on the statements they cite, proved above for families: (1) is Corollary 26.6, infeasibility meaning that some proper wall is not positive, so that the period diverges (Theorem 8.7); (2) is Theorem 26.13 and Corollary 26.14; (4) uses that the admissible points form an open subset of the real points of the pins, the conditions $\mathbf{c}^X \in w_X \operatorname{ri} \mathcal{N}_X$ being open there, and the bounds of Theorem 25.12(iii), uniform on compact sets of admissible points; (5) is Theorem 26.16, the substituted family at a vertex v having the cores $\mathcal{H}_{j,v}$ and, as its cell families, the subtree cell families of the vertices directly below v. The reusable data are those of Corollary 25.13, one Gramma for each orbit of nodes.

Proposition 26.19 (What the network costs). *As stated, for a family.*

Proof. (i) The fibre of Theorem 26.13 has dimension $(2N-1)(n-1)$, and for one table each pooled pair removes one coordinate (Proposition 26.15). Opening the period of a prime node $\mathcal{H}_{j,v}$ at one full lean on its share side adds $|\mathcal{H}_{j,v}| - n_{j,v}$ coordinates (Corollary 26.8), so the two full leans add $2(|\mathcal{H}_{j,v}| - n_{j,v})$; series and parallel nodes have closed forms (Proposition 26.9). The atom formula (Corollary 18.16) has the shares $\mathbf{a}_j, \mathbf{b}_j \in \mathbb{C}^{\mathcal{B}_j}$ against the $2N$ total pins and the $n-1$ pins $\langle \boldsymbol{\delta} \rangle_e = \mu_e$, $e \neq g$: dimension $\sum_j 2|\mathcal{B}_j| - 2N - n + 1$. After its even shares close (Theorem 20.11(iv)) the fibre of differences has dimension $\sum_j (|\mathcal{B}_j| - 1) - (n-1)$, and each table keeps one scale integral: $\sum_j |\mathcal{B}_j| - n + 1$ in all.

(ii) is Corollary 25.13: one Gramma of n_v variables for each orbit of nodes, the orbits taken over all the tables.

(iii) By Theorem 26.16(ii) a point of the Mellin transform of the law of a subtree cell family with the top node v costs a fibre integral of dimension $(2N-1)(|\mathcal{E}_v| + k_v - 1)$, $k_v = |G_v| - 1$ the number of vertices directly below v, that is $(2N-1)(|\mathcal{E}_v| + |G_v| - 2)$; at the root Theorem 26.16(i) costs $(2N-1)(|\mathcal{E}_o| + |G_o| - 1)$. Their integrands need the periods of the tables of the node at their full leans at the loads of the fibre, closed at series and parallel nodes and on the share side at a prime node (Corollary 26.8). □

Proposition 26.20 (Product weights are twists). *As stated, for every family.*

Proof. $K_{F^{\boldsymbol{\zeta}},j}(\alpha) = \sum_T \theta_{j,T} \boldsymbol{\zeta}_j^T \alpha^T = K_j(\boldsymbol{\zeta}_j \circ \alpha)$, and $\Psi_{F^{\boldsymbol{\zeta}},j}(\alpha) = \sum_T \theta_{j,T} \boldsymbol{\zeta}_j^T \alpha^{\mathcal{E}\setminus T} = \boldsymbol{\zeta}_j^{\mathcal{E}} \sum_T \theta_{j,T} (\alpha/\boldsymbol{\zeta}_j)^{\mathcal{E}\setminus T} = \boldsymbol{\zeta}_j^{\mathcal{E}} \Psi_j(\alpha/\boldsymbol{\zeta}_j)$. These are the letters of $F[\mathbf{x}]$ with $\mathbf{x}_j^K = \boldsymbol{\zeta}_j$ and $\mathbf{x}_j^\Psi = \boldsymbol{\zeta}_j^{-1}$ (Definition 22.1), the cobasis letters multiplied by $\boldsymbol{\zeta}_j^{\mathcal{E}}$, and $(\boldsymbol{\zeta}_j^{\mathcal{E}})^{-t_j} = \boldsymbol{\zeta}_j^{-t_j \mathbf{1}}$ gives the first identity. By the torus relation of Definition 22.1 for the family of the one letter K_j, the period of $K_j(\boldsymbol{\zeta}_j \circ \alpha)^{-s_j}$ at $\mathbf{a}$ is $\boldsymbol{\zeta}_j^{-\mathbf{a}} P_{\mathcal{B}_j}(\mathbf{a}; s_j, 0)$, and for the one letter Ψ_j the period of $\big(\boldsymbol{\zeta}_j^{\mathcal{E}} \Psi_j(\alpha/\boldsymbol{\zeta}_j)\big)^{-t_j}$ at $\mathbf{b}$ is $\boldsymbol{\zeta}_j^{-t_j \mathbf{1}} \boldsymbol{\zeta}_j^{\mathbf{b}} P_{\mathcal{B}_j}(\mathbf{b}; 0, t_j)$. In the lean convolution of $F^{\boldsymbol{\zeta}}$ the integrand is therefore that of F times $\prod_j \boldsymbol{\zeta}_j^{-t_j \mathbf{1}} \boldsymbol{\zeta}_j^{\mathbf{b}_j - \mathbf{a}_j}$. With one $\boldsymbol{\zeta}$ for every table, the torus relation with the vector $\boldsymbol{\zeta}^{-1}$ on every letter gives $P_{F[\mathbf{x}]} = \boldsymbol{\zeta}^{-\mathbf{m}} P_{F[\mathbf{x}']}$ for $\mathbf{x}_j^K = \boldsymbol{\zeta}$, $\mathbf{x}_j^\Psi = \boldsymbol{\zeta}^{-1}$ and $\mathbf{x}_j'^K = \mathbf{1}$, $\mathbf{x}_j'^\Psi = \boldsymbol{\zeta}^{-2}$, and $\prod_j \boldsymbol{\zeta}^{-t_j \mathbf{1}} = \boldsymbol{\zeta}^{-|\mathbf{t}|\mathbf{1}}$. Weights at one mark g are the $\boldsymbol{\zeta}_j$ equal to 1 off g. □

Proposition 26.21 (Carrying a calculation through a change, in hold form). *As stated, for every family.*

Proof. In Theorem 26.13 the integrand is the product of the node periods at the node loads over the Beta corners at the marker loads, times the twists. (i) The exponents of table j enter the pins $|\mathbf{a}_j| = r_j s_j$ and $|\mathbf{b}_j| = r_j^* t_j$ and the marker loads $k_{j;v,\mathfrak{e}} = s_j r_{j,v}^{\mathfrak{e}} - a_{j,\mathcal{E}_v^{\mathfrak{e}}}$ and $l_{j;v,\mathfrak{e}} = t_j r_{j,v}^{*\mathfrak{e}} - b_{j,\mathcal{E}_v^{\mathfrak{e}}}$, affine in (s_j, t_j), and the corners through them; the node periods are functions of the node loads alone (Definition 25.9), and the native loads of the new data are admissible (Proposition 25.10(iii)). (ii) In the coordinates of Theorem 25.12(ii) the masses enter $\mathbf{a}_1 = \mathbf{m} - \sum_{j \geq 2} \mathbf{a}_j - \sum_j \mathbf{b}_j$ alone, the loads at e_0 of the other letters being fixed by their totals. (iii) is Proposition 26.20, for one node read for its table. (iv) The node periods are the only data of a node in the integrand; a replaced node of the same rank keeps the ranks of the branches and so the marker loads, and Theorem 26.13 applies to the new trees, whose nodes are molecules with markers neither loops nor coloops. (v) By Theorem 26.16(ii) the transform at a vertex is computed from the node there and the transforms of the vertices directly below it, so a change at one node changes the transforms on its path to the root only. □

Proposition 26.22 (The exponents are moment indices). *As stated, for every family, any of its letters being closed.*

Proof. The walls are affine in $(\mathbf{s},\mathbf{t})$ (Definition 8.1), so I, the intersection of the hyperplane with the open orthant and the open half-spaces $\kappa_S>0$, is relatively open and convex. On I the period converges (Theorem 8.7), and $\mathbf{m}>0$, every singleton wall $m_e-\sum_j(s_j d_j(\{e\})+t_j d_j^*(\{e\}))$ being positive and the counts nonnegative. Fix i and apply Lemma 16.2 to the form of F with $h=L_i^{1/g_i}$, positive and homogeneous of degree one, and $\varphi(\rho)=\rho^{w_i g_i}e^{-\rho^{g_i}}$, for which $\int_0^\infty\varphi(\rho)\,d\rho/\rho=\Gamma(w_i)/g_i$: the integrand $x^{\mathbf{m}-\mathbf{1}}\prod_{i'}L_{i'}^{-w_{i'}}$ times $\varphi(h)=L_i^{w_i}e^{-L_i}$ is $x^{\mathbf{m}-\mathbf{1}}e^{-L_i}\prod_{i'\neq i}L_{i'}^{-w_{i'}}$, which gives the first identity. Every letter being positive on the orthant and every $w_{i'}>0$, $L_{i'}(x)^{-w_{i'}}=\Gamma(w_{i'})^{-1}\int_0^\infty\lambda^{w_{i'}-1}e^{-\lambda L_{i'}(x)}d\lambda$, and Tonelli's theorem gives the second identity, the integral over x being $\mathsf{G}_i(\mathbf{m};\boldsymbol{\lambda})$, the Gramma of the concatenated configuration (Definition 2.1). The derivative $\partial^k_{\lambda_{i'}}\mathsf{G}_i$ is $(-1)^k$ times the integral with the further factor $L_{i'}^k$, which gives the complete monotonicity. By Proposition 8.12(iii), $P_F(\mathbf{m};\mathbf{s},\mathbf{t})/\Gamma_1^n\begin{bmatrix}\mathbf{m}\\ m_{\mathcal{E}}\end{bmatrix}$ is the moment generating function, in the exponents, of $\big(-\log K_j(U),-\log\Psi_j(U)\big)_j$ for $U\sim\mathrm{Dir}_{\mathbf{m}}$, and by Hölder's inequality a moment generating function is log-convex on the convex set where it is finite; $\Gamma_1^n\begin{bmatrix}\mathbf{m}\\ m_{\mathcal{E}}\end{bmatrix}$ does not depend on the exponents. □

50.27 Chapter 27: finite interfaces and certified enclosures

Definition 27.1 (The channel law; moment vectors). As stated; cells with the same hinges on the same marks are kept together by reading their channels jointly.

Proposition 27.2 (The channel law composes). *As stated, for cells kept together and for every cell family.*

Proof. By Theorem 3.12 with the blocks B_1 and B_2, $U\sim\mathrm{Dir}_{(\mathbf{m}_1,\mathbf{m}_2)}$ on $\Delta_{B_1\sqcup B_2}$ is $U|_{B_l}=V_lU_l$ with $(V_1,V_2)\sim\mathrm{Dir}_{(m_{B_1},m_{B_2})}$ and $U_l\sim\mathrm{Dir}_{\mathbf{m}_l}$, independent. In every table j the channels of the spliced cell are the bilinear map of Theorem 21.14(iii) applied to the channels of the two cells of table j, and a channel c has $c(V_lU_l)=V_l^{\deg c}c(U_l)$. So $\mathrm{ch}(\mathcal{A}_{12})(U)$ is the image of the replaced channel vectors under the bilinear map applied table by table, and its law is the channel law of $\mathcal{A}_{12}$. For the tables of a family kept together without hinges the channels are the letters K_j and Ψ_j, and Proposition 8.12(i) is the stated reading.

For the cell family F, by Definitions 23.1 and 21.1 at the point $\mathrm{ch}(\mathcal{A})(u)$, $\gamma^K_{\mathcal{A}_j}=x_{j,0}/x_{j,1}$ and $\gamma^\Psi_{\mathcal{A}_j}=x^*_{j,1}/x^*_{j,0}$, so $\gamma^K_{\mathcal{A}_j}/\gamma^K_{\mathcal{A}_1}=x_{j,0}x_{1,1}/(x_{j,1}x_{1,0})$ and $\gamma^\Psi_{\mathcal{A}_j}/\gamma^K_{\mathcal{A}_1}=x^*_{j,1}x_{1,1}/(x^*_{j,0}x_{1,0})$: $\boldsymbol{\varrho}_F=R_F\circ\mathrm{ch}(\mathcal{A})$. The base form is $\phi_F(du)=\varpi(\mathrm{ch}(\mathcal{A})(u))\,u^{\mathbf{m}-\mathbf{1}}d\omega_B(u)$ with $\varpi=\prod_j x_{j,1}^{-s_j}x_{j,0}^{*-t_j}(x_{1,0}/x_{1,1})^{-\kappa_F}$, the factor $\gamma^K_{\mathcal{A}_1}(u)^{-\kappa_F}$ being $(x_{1,0}/x_{1,1})^{-\kappa_F}$, and $u^{\mathbf{m}-\mathbf{1}}d\omega_B=\Gamma_1^{|B|}\begin{bmatrix}\mathbf{m}\\ m_B\end{bmatrix}\mathrm{Dir}_{\mathbf{m}}(du)$ (Definition 3.10). For a positive measure μ and positive functions, $(R\circ c)_*\big((\varpi\circ c)\,\mu\big)=R_*\big(\varpi\,c_*\mu\big)$, both sides giving $\int H(R(c(u)))\,\varpi(c(u))\,d\mu(u)$ against every Borel $H\geq0$. With $c=\mathrm{ch}(\mathcal{A})$ and $\mu=\Gamma_1^{|B|}\begin{bmatrix}\mathbf{m}\\ m_B\end{bmatrix}\mathrm{Dir}_{\mathbf{m}}$ this is the display. □

Theorem 27.3 (Gamma draws close the moments). *As stated, for cells kept together.*

Proof. The reference, proof of thm:gammalift, uses of the channel vector only that it is a vector of polynomials on the marks, homogeneous of known degrees, that the Gamma draws on disjoint sets of marks are independent, and that a splicing acts on the channel vectors by a bilinear map

whose every product has the degree of the channel it gives. For cells kept together the channel vector is the joint vector $(\mathrm{ch}(\mathcal{A}_j))_j$, and a splicing acts table by table, so on the joint vectors by the direct sum over the tables of the maps of Theorem 21.14(iii), again bilinear with that property. So (i), (iii) and (iv) hold word for word. In (ii) the joint channels of $\mathcal{A}_{12}$ at α are $\mathrm{sp}\big(\mathrm{ch}(\mathcal{A}_1)(\alpha|_{B_1}), \mathrm{ch}(\mathcal{A}_2)(\alpha|_{B_2})\big)$, each a sum of products of one joint channel of each cell, so a monomial of degree $|\mathbf{k}|$ in them expands into monomials of degree $|\mathbf{k}|$ in the joint channels of each cell, and the independence of $\alpha|_{B_1}$ and $\alpha|_{B_2}$ gives the formula. In (v) the joint channels are bounded on Δ_B, so by (iii) their moments determine their law, and Proposition 27.2 composes it. □

Theorem 27.9 (Taylor coefficients in the weights are periods with walls at least as high). *As stated, at real exponents of any sign.*

Proof. For $u \in \Delta_{\mathcal{E}}$ put $y_i(u) = \sum_j \zeta_j D_{ij}(u)/L_i(u)$. Write $L_i = \sum_{\boldsymbol{\gamma}} c_{i,\boldsymbol{\gamma}} u^{\boldsymbol{\gamma}}$ with $c_{i,\boldsymbol{\gamma}} > 0$; D_{ij} has its support in that of L_i, so $D_{ij} = \sum_{\boldsymbol{\gamma}} c_{i,\boldsymbol{\gamma}} v_{i,\boldsymbol{\gamma},j} u^{\boldsymbol{\gamma}}$ with real $v_{i,\boldsymbol{\gamma},j}$, and with $V_{ij} = \max_{\boldsymbol{\gamma}} |v_{i,\boldsymbol{\gamma},j}|$, $|D_{ij}| \le V_{ij} L_i$ on the orthant and $|y_i| \le r_i(\boldsymbol{\zeta}) := \sum_j |\zeta_j| V_{ij}$; let every $r_i(\boldsymbol{\zeta}) < 1$. For real w and $|y| < 1$, $(1+y)^{-w} = \sum_{l \ge 0} (-1)^l \frac{(w)_l}{l!} y^l$, and $|(w)_l| \le (|w|)_l$ since $|w+k| \le |w| + k$, so the series of the moduli is at most $\sum_l \frac{(|w|)_l}{l!} |y|^l = (1-|y|)^{-|w|}$. With the multinomial expansion of $y_i^{l_i}$,

$$L_i(\boldsymbol{\zeta})^{-w_i} = L_i^{-w_i}(1+y_i)^{-w_i} = \sum_{(l_{ij})_j} \frac{(-1)^{l_i}(w_i)_{l_i}}{\prod_j l_{ij}!}\, L_i^{-w_i - l_i} \prod_j \big(\zeta_j D_{ij}\big)^{l_{ij}}, \qquad l_i = \sum_j l_{ij},$$

and the product over i of the series of the moduli is at most $\prod_i L_i^{-w_i}(1 - r_i(\boldsymbol{\zeta}))^{-|w_i|}$. Against $u^{\mathbf{m}-\mathbf{1}} d\omega_{\mathcal{E}}$ this bound is integrable, $P(\mathbf{0})$ converging at the real data; so termwise integration is justified, P is a convergent power series on $\{r_i(\boldsymbol{\zeta}) < 1 \ \forall i\}$, and its coefficients are the stated ones. After the numerators are expanded every term is a coefficient times $u^{\mathbf{m}+\boldsymbol{\gamma}-\mathbf{1}} \prod_i L_i^{-w_i - l_i}$, $\boldsymbol{\gamma}$ a sum, over i, of l_i exponents of the support of L_i. So $|\boldsymbol{\gamma}| = \sum_i l_i g_i$ and the term is balanced, and $\gamma_S \ge \sum_i l_i d_i(S)$ with $d_i(S)$ the least value of $\langle \mathbf{1}_S, \cdot \rangle$ on the support of L_i, which is the count $d_j(S)$ or $d_j^*(S)$ of the letter in the walls (Definition 8.1). So $\kappa'_S = \kappa_S + \gamma_S - \sum_i l_i d_i(S) \ge \kappa_S > 0$, and the term converges by Theorem 8.7, whose criterion holds for exponents of any sign. □

Theorem 27.10 (A uniform certificate for weights). *As stated, at real exponents of any sign.*

Proof. Let $|\zeta_j| \le R_j$, so that $|y_i| \le r_i < 1$ in the notation of the proof of Theorem 27.9. For real w_i, $|(1+y_i)^{-w_i}| = |1+y_i|^{-w_i}$, the real part of $1+y_i$ being positive, and $1 - r_i \le |1+y_i| \le 1 + r_i$, so $|L_i(\boldsymbol{\zeta})^{-w_i}| \le L_i^{-w_i} \max\big((1-r_i)^{-w_i}, (1+r_i)^{-w_i}\big)$; integrating, $|P(\boldsymbol{\zeta})| \le M$. The radii can be enlarged a little with every $r_i < 1$ kept, so P is holomorphic near the closed polydisc by Theorem 27.9, and the Cauchy estimates give $|[\boldsymbol{\zeta}^{\mathbf{k}}]P| \le M \mathbf{R}^{-\mathbf{k}}$; the bounds on the Taylor remainder follow from these as in the reference, proof of thm:weightbank, there being $\binom{k+p-1}{p-1}$ multi-indices of degree k. For the explicit bound on $P(\mathbf{0})$: by Theorem 8.5(ii) and Theorem 8.7, off the balance wall and then on it by continuity, $P(\mathbf{0}) = \sum_\pi \int_{[0,1]^{n-1}} \prod_k q_k^{\kappa_{U_{\pi,k}}^{-1}} \prod_i L_{i,\pi}(q)^{-w_i}\, dq$. Each sector letter has nonnegative coefficients and is increasing in every q_k, so $L_{i,\pi}(\mathbf{0}) \le L_{i,\pi}(q) \le L_{i,\pi}(\mathbf{1})$ and $L_{i,\pi}(q)^{-w_i} \le \max\big(L_{i,\pi}(\mathbf{0})^{-w_i}, L_{i,\pi}(\mathbf{1})^{-w_i}\big)$ for every real w_i, and $\int_{[0,1]^{n-1}} \prod_k q_k^{\kappa_{U_{\pi,k}}^{-1}} dq = \prod_k \kappa_{U_{\pi,k}}^{-1}$. The enclosure of Proposition 15.12 holds for real data of any sign, its error bound being written with $\sum_j (|s_j| + |t_j|)$, so its upper end bounds $\prod_j K_j(\mathbf{1})^{s_j+t_j} P(\mathbf{0})$ from above. □

50.28 Chapter 28: bunches of any width

Definition 28.1 (Seam). As stated: the pair constant does not depend on the choice.

Proof. Let $p \in C$ and $X \in D$ with $p \sqcup X \in \mathcal{B}$. The child at p carries the weight $\theta_{p\sqcup X}$ on its basis X (12.2) and is w_p times the child of the station C, so $\theta_{p\sqcup X} = w_p\,\theta_{(C),X}$; the room child at X carries $\theta_{p\sqcup X}$ on its basis p and is w'_X times the room child of the station D, so $\theta_{p\sqcup X} = w'_X\,\theta_{(D),p}$. Hence $\theta_{p\sqcup X}/(w_p w'_X)$ is $\theta_{(C),X}/w'_X$, which does not depend on p, and $\theta_{(D),p}/w_p$, which does not depend on X. The children in a station are positive multiples of one another and so have the same bases: $p' \sqcup X \in \mathcal{B}$ for every $p' \in C$ and $p \sqcup X' \in \mathcal{B}$ for every $X' \in D$. Changing p and then X one at a time, the quotient takes one value at all pairs of $C \times D$. □

Proposition 28.2 (The seam identity). *As stated; in (v) the seam matrix of an extreme excess is a single entry exactly when the weights of that level factor.*

Proof. Parts (i)–(iv) and (vi), and in (v) the room children and the seam letters at the two extremes, are the reference, proof of prop:seamidentity. Let $i \in \{0, c(B)\}$. By 12.19 every pattern of excess i and every room side of excess i make a basis, so every station of patterns of excess i is compatible with every station of room sides of excess i.

Let the weights of the level factor along these products, $\theta_{p\sqcup X} = \theta'_p\,\theta''_X$ for the patterns p and the room sides X of excess i, with positive θ' and θ''. The child at a pattern p of excess i is the table on R whose bases are all the room sides of excess i, with the weights $\theta'_p\,\theta''_X$: it is θ'_p times one table. So the patterns of excess i form one station and H_i has one row. The columns of a matrix with one row are proportional, and by (iv) no two stations of $\mathcal{D}_i$ have proportional columns; so H_i has one column, and its entry is positive, the pair being compatible.

Conversely let H_i be a single entry h_{CD}. The patterns of excess i then form the one station C and its room sides the one station D, and (ii) gives $\theta_{p\sqcup X} = h_{CD}\,w_p\,w'_X$ for every such p and X: the weights of the level factor along these products, with the factors $h_{CD}\,w_p$ and w'_X. □

Proposition 28.3 (The width ladder). *As stated; in (i) and (ii) the seam is one rectangle at each excess exactly when the weights factor across B and R, and the closing sentence holds at every width.*

Proof. (i) That $c(B) = 0$ exactly when B is a union of molecules, with one excess, every pattern meeting every room side, and the letters $K = \mathsf{x}_0^{\mathsf{T}} H_0\,\mathsf{y}_0$ and $\Psi = \mathsf{x}_0^{*\mathsf{T}} H_0\,\mathsf{y}_0^*$, is the reference, proof of prop:ladder(i). The one excess is extreme, so by 28.2(v) the seam is one rectangle exactly when the weights of its level factor along the products $p \sqcup X$. Every basis lies in this level, so this is a factoring $\theta_T = \theta'_{T\cap B}\,\theta''_{T\cap R}$ across B and R, and conversely. With one station C and one station D, 28.2(iii) reads $K = h_{CD}\,\mathsf{x}_C\,\mathsf{y}_D$ and $\Psi = h_{CD}\,\mathsf{x}_C^*\,\mathsf{y}_D^*$.

(ii) That $c(B) = 1$ exactly when there are two excesses, both extreme, is the reference, proof of prop:ladder(ii). By 28.2(v) the excess i is one rectangle exactly when the weights of its level factor, $\theta_{p\sqcup X} = \theta'_{i,p}\,\theta''_{i,X}$ for the patterns p and the room sides X of excess i. If both levels factor, put $\theta'_p = \theta'_{i(p),p}$ and $\theta''_X = \theta''_{i(X),X}$, each pattern and each room side having one excess; the pattern and the room side of a basis have one excess, so $\theta_T = \theta'_{T\cap B}\,\theta''_{T\cap R}$ for every basis T. Conversely a factoring across B and R restricts to a factoring of each level. The seam letters, the room station letters and the room-station factorization are the reference's (proof of prop:ladder(ii), and exercise ex:widthone).

(iii) and the closing sentence. A matrix with one row has proportional columns, and a matrix with one column proportional rows; so by 28.2(iv) an excess with one station on one side has one

station on the other, at every width. The criterion for level form is 14.12, which does not restrict the width. In level form the children at the patterns of one excess are equal, so these patterns form one station; the excess then has one station on each side and is one rectangle. That an excess $0 < i < c(B)$ can carry several rectangles is the reference's (prop:ladder(iii) and exercise ex:prismseam). □

Proposition 28.6 (Symmetries of a seam). *As stated; in (iii) an exchanging bijection is read at every lean, and it carries the law of B at the lean $\boldsymbol{\delta}$ to its law at $-\boldsymbol{\delta}$.*

Proof. Parts (i) and (ii), the first sentence of (iii), the carrying bijections and the sentence on the potential are the reference, proof of prop:seamsym.

Let g keep B and the masses and exchange the family, and let $j \mapsto j'$ be the bijection of its tables of 11.13. The pairs are kept, $(\sigma_{j'}, \delta_{j'}) = (\sigma_j, \delta_j)$, so at the lean $-\boldsymbol{\delta}$ table j' carries the exponents $(t_{j'}, s_{j'}) = (t_j, s_j)$. Read every function of α_B at $g^*\alpha$. This permutes the coordinates of Δ_B and keeps $u^{\mathbf{m}_B - \mathbf{1}} d\omega_B$, since g keeps B and the masses. By 14.10, $c_{j'}(B) = c_j(B)$, $d_{j'}(B) = |B| - r_j(B) = d_j^*(B)$ and $d_{j'}^*(B) = d_j(B)$.

(a) By (ii) the seam letter V_{jD} of K_j at the excess $i(D)$ is, at $g^*\alpha$, the seam letter $V_{j'D'}^*$ of $\Psi_{j'}$ at the excess $c_j - i(D)$, and V_{jD}^* is $V_{j'D'}$. Summing over the stations of one excess, $V_j^{(i)} = V_{j'}^{*(c_j - i)}$ and $V_j^{*(i)} = V_{j'}^{(c_j - i)}$.

(b) K_j is active at $\boldsymbol{\delta}$ exactly when $s_j > 0$, that is exactly when $\Psi_{j'}$ is active at $-\boldsymbol{\delta}$; likewise Ψ_j and $K_{j'}$. The sum $\kappa_B + \kappa_B^{\mathrm{top}} = \sum_j (s_j + t_j) c_j$ is the same at the two leans.

(c) By (a) and (b) the scale of the piece at $\boldsymbol{\delta}$ (28.5) is

$$\prod_j \Big(\frac{V_{j'}^{*(0)}}{V_{j'}^{*(c_j)}} \Big)^{s_j/(\kappa_B + \kappa_B^{\mathrm{top}})} \Big(\frac{V_{j'}^{(c_j)}}{V_{j'}^{(0)}} \Big)^{t_j/(\kappa_B + \kappa_B^{\mathrm{top}})},$$

which is the scale at $-\boldsymbol{\delta}$, where $\Psi_{j'}$ carries the exponent s_j and $K_{j'}$ the exponent t_j.

(d) The wall at $-\boldsymbol{\delta}$ is $m_B - \sum_j \big(t_j d_{j'}(B) + s_j d_{j'}^*(B) \big) = m_B - \sum_j \big(s_j d_j(B) + t_j d_j^*(B) \big) = \kappa_B$.

(e) By (a), (c) and (d) the scale form at $\boldsymbol{\delta}$,

$$u^{\mathbf{m}_B - \mathbf{1}} \prod_j (V_j^{(0)})^{-s_j} (V_j^{*(c_j)})^{-t_j} (\gamma_B^\rho)^{-\kappa_B} d\omega_B,$$

is the scale form at $-\boldsymbol{\delta}$.

(f) For a station D of excess $i(D)$ and its image D' of excess $c_j - i(D)$,

$$\varrho_{jD}^\rho = \frac{V_{jD}}{V_j^{(0)} \, (\gamma_B^\rho)^{i(D)}} = \frac{V_{j'D'}^*}{V_{j'}^{*(c_j)} \, (\gamma_B^\rho)^{c_j - i(D')}},$$

the coordinate $\varrho_{j'D'}^{\rho *}$ at $-\boldsymbol{\delta}$; likewise $\varrho_{jD}^{\rho *}$ is the coordinate $\varrho_{j'D'}^\rho$ at $-\boldsymbol{\delta}$.

So the seam vector at $\boldsymbol{\delta}$, followed by the map of the coordinates, is the seam vector at $-\boldsymbol{\delta}$ read at $g^*\alpha$, and by (e) the scale forms correspond. The image of the law at $\boldsymbol{\delta}$ is therefore the law at $-\boldsymbol{\delta}$. By (a) and (b) the relations defining the seam torus at $\boldsymbol{\delta}$ go over into those at $-\boldsymbol{\delta}$. At the centre $\boldsymbol{\delta} = -\boldsymbol{\delta}$, and the law is kept. □

Lemma 28.8 (Absorbing a piece of any width). *As stated, with functions f_l homogeneous of degree one in their second argument.*

Proof. Take the section $h = \gamma^{\rho}_{B}(\alpha_B) + |\alpha_Z|$, a positive function of degree one on $(0,\infty)^{B\sqcup Z}$, and write $\alpha_B = \lambda u$ with $\lambda > 0$ and $u \in \Delta_B$ (2.7).

- *The seam letters along the scale.* Let f_l be assigned to K_j. By 28.5, $V_{jD} = V_j^{(0)}\,(\gamma^{\rho}_{B})^{i(D)}\varrho^{\rho}_{jD}$ on Δ_B, and V_{jD} is homogeneous of degree $d_j + i(D)$. Hence

$$V_{jD}(\lambda u) = \lambda^{d_j} V_j^{(0)}(u)\,\big(\lambda\gamma^{\rho}_{B}(u)\big)^{i(D)}\varrho^{\rho}_{jD}(u),$$
$$\text{that is}\quad \mathbf{V}_l(\lambda u) = V_l(\lambda u)\,\mathbf{x}_l(\alpha_g),$$

  at $\alpha_g = \lambda\gamma^{\rho}_{B}(u)$ and $\mathbf{x} = \boldsymbol{\varrho}^{\rho}_{B}(u)$, with $V_l(\lambda u) = \lambda^{d_j}V_j^{(0)}(u) > 0$. For Ψ_j the same holds with $V^*_{jD} = V_j^{*(c_j)}(\gamma^{\rho}_{B})^{c_j - i(D)}\varrho^{\rho *}_{jD}$, of degree $d^*_j + c_j - i(D)$, and $V_l(\lambda u) = \lambda^{d^*_j}V_j^{*(c_j)}(u)$.

- *Homogeneity.* Since f_l is homogeneous of degree one in its second argument,

$$f_l\big(\alpha_Z, \mathbf{V}_l(\lambda u)\big) = V_l(\lambda u)\, f_l\big(\alpha_Z, \mathbf{x}_l(\alpha_g)\big).$$

  So the arguments of H are the $f_l(\alpha_Z, \mathbf{x}_l(\alpha_g))$. The exponents assigned to each active letter add to its exponent, so

$$\prod_l f_l\big(\alpha_Z, \mathbf{V}_l(\lambda u)\big)^{-a_l} = \lambda^{-\sum_j (s_j d_j + t_j d^*_j)} \prod_j V_j^{(0)}(u)^{-s_j} V_j^{*(c_j)}(u)^{-t_j} \prod_l f_l\big(\alpha_Z, \mathbf{x}_l(\alpha_g)\big)^{-a_l}.$$

- *The scale and the stand-in.* With $\alpha_B^{\mathbf{m}_B - \mathbf{1}}\, d\alpha_B = \lambda^{m_B - 1} u^{\mathbf{m}_B - \mathbf{1}}\, d\lambda\, d\omega_B(u)$, the power of λ is $\lambda^{\kappa_B - 1}$. At fixed u substitute $\alpha_g = \lambda\gamma^{\rho}_{B}(u)$, so that $\lambda^{\kappa_B - 1} d\lambda = \gamma^{\rho}_{B}(u)^{-\kappa_B}\alpha_g^{\kappa_B - 1} d\alpha_g$. In the coordinates (u, α_g, α_Z) the form ω is then $\phi^{\rho}_{B}(du)$ times $\omega_{\boldsymbol{\varrho}^{\rho}_{B}(u)}$ (28.5), and $h = \alpha_g + |\alpha_Z|$.

- *The integral.* At fixed u the map $(\lambda, \alpha_Z) \mapsto (\alpha_g, \alpha_Z)$ intertwines the scalings of the two orthants, so $\omega_{\boldsymbol{\varrho}^{\rho}_{B}(u)}$ is homogeneous of degree zero together with ω. By 16.2, the integral of a form homogeneous of degree zero over a section does not depend on the section. Tonelli's theorem, applied to the nonnegative integrand, then gives

$$\int_{\{h=1\}} \omega = \int_{\Delta_B} \phi^{\rho}_{B}(du) \int_{\{\alpha_g + |\alpha_Z| = 1\}} \omega_{\boldsymbol{\varrho}^{\rho}_{B}(u)} = \int \Big(\int_{\{h'=1\}} \omega_{\mathbf{x}} \Big)\, d\big((\boldsymbol{\varrho}^{\rho}_{B})_* \phi^{\rho}_{B}\big)(\mathbf{x}).$$

This is the reference's proof (proof of lem:absorbwidth). There, linearity of the f_l enters only through the identity $f_l(\alpha_Z, \mathbf{V}_l(\lambda u)) = V_l(\lambda u)\, f_l(\alpha_Z, \mathbf{x}_l(\alpha_g))$, which homogeneity of degree one gives. □

Remark. At width one with factoring weights, normalized as in 28.11, the seam letters of K_j are $(K_{\mathcal{B}_j/R}, K_{\mathcal{B}_j|B})$ and those of Ψ_j are $(\Psi_{\mathcal{B}_j/R}, \Psi_{\mathcal{B}_j|B})$ (Lemma S13). The positive continuous functions homogeneous of degree one in the second argument are, for K_j, $f_l(\alpha_Z, (y_0, y_1)) = y_0\, f(\alpha_Z, y_1/y_0)$, and for Ψ_j, $f_l(\alpha_Z, (y_0, y_1)) = y_1\, f(\alpha_Z, y_0/y_1)$, with f positive and continuous on $(0,\infty)^Z \times (0,\infty)$. At the seam letters they are $K_{\mathcal{B}_j/R}\, f(\alpha_Z, \gamma^K_{j,B})$ and $\Psi_{\mathcal{B}_j|B}\, f(\alpha_Z, \gamma^{\Psi}_{j,B})$. These are the factors $L_i\, f_i(\alpha_Z, \gamma_i)$ of 23.2 for the cell family F^+_B, with arbitrary f_i. Linear functions f_l give only the f_i that are affine in the hinge value; homogeneity of degree one gives all of them.

Lemma S13. *Let a bunch B have width one in table j of a family, the weights factoring across B and R, $\theta_{j,T} = \theta'_{j,T\cap B}\,\theta''_{j,T\cap R}$, with the stations D_0 and D_1 of the excesses 0 and 1 (28.3(ii)). In this statement write $\hat\theta_i$ for the largest value of θ''_j on the room sides of excess i, and read $\mathcal{B}_j/R$ and $\mathcal{B}_j|B$ with the weights θ'_j and $\mathcal{B}_j|R$ and $\mathcal{B}_j/B$ with the weights θ''_j.*

(i) $K_{j,(D_0)} = \hat\theta_0 K_{\mathcal{B}_j/R}$, $\Psi_{j,(D_0)} = \hat\theta_0\Psi_{\mathcal{B}_j/R}$, $K_{j,(D_1)} = \hat\theta_1 K_{\mathcal{B}_j|B}$ *and* $\Psi_{j,(D_1)} = \hat\theta_1\Psi_{\mathcal{B}_j|B}$; *and* $\mathsf{y}_{jD_0} = K_{\mathcal{B}_j|R}/\hat\theta_0$, $\mathsf{y}^*_{jD_0} = \Psi_{\mathcal{B}_j|R}/\hat\theta_0$, $\mathsf{y}_{jD_1} = K_{\mathcal{B}_j/B}/\hat\theta_1$ *and* $\mathsf{y}^*_{jD_1} = \Psi_{\mathcal{B}_j/B}/\hat\theta_1$.

(ii) For $i = 0, 1$, divide θ''_j by $\hat\theta_i$ on the room sides of excess i and multiply θ'_j by $\hat\theta_i$ on the patterns of excess i. This gives a factorization of the same weights with $\hat\theta_0 = \hat\theta_1 = 1$, in which θ''_j is the system of the multipliers of the room sides (28.1). The seam letters and the room station letters do not depend on the factorization. In the normalized factorization

$$\gamma^K_{j,B} = \frac{K_{j,(D_1)}}{K_{j,(D_0)}}, \qquad \gamma^\Psi_{j,B} = \frac{\Psi_{j,(D_0)}}{\Psi_{j,(D_1)}}, \qquad \gamma^K_{j,R} = \frac{\mathsf{y}_{jD_0}}{\mathsf{y}_{jD_1}}, \qquad \gamma^\Psi_{j,R} = \frac{\mathsf{y}^*_{jD_1}}{\mathsf{y}^*_{jD_0}}.$$

In a factorization with the constants $\hat\theta_0$ and $\hat\theta_1$, the four ratios on the right are $(\hat\theta_1/\hat\theta_0)\gamma^K_{j,B}$, $(\hat\theta_0/\hat\theta_1)\gamma^\Psi_{j,B}$, $(\hat\theta_1/\hat\theta_0)\gamma^K_{j,R}$ and $(\hat\theta_0/\hat\theta_1)\gamma^\Psi_{j,R}$.

Proof. (i) By 19.4 the bases of table j are the $X \sqcup Y$ with $X \in \mathcal{B}_j|B$ and $Y \in \mathcal{B}_j/B$, at the level $r_j(B)$, and with $X \in \mathcal{B}_j/R$ and $Y \in \mathcal{B}_j|R$, at the level $d_j(B)$.

- So the patterns and the room sides of excess 0 are the bases of $\mathcal{B}_j/R$ and of $\mathcal{B}_j|R$, those of excess 1 the bases of $\mathcal{B}_j|B$ and of $\mathcal{B}_j/B$, and every pattern meets every room side of its excess.
- The room child at a room side X of excess 0 (28.1) is the table on B with the bases of $\mathcal{B}_j/R$ and the weights $\theta'_{j,p}\,\theta''_{j,X}$, that is $\theta''_{j,X}$ times $\mathcal{B}_j/R$ with the weights θ'_j.
- These room children are positive multiples of one another, so the room sides of excess 0 form the one station D_0. Its multipliers are $w'_X = \theta''_{j,X}/\hat\theta_0$, the largest equal to 1, and the room child of the station is $\hat\theta_0$ times $\mathcal{B}_j/R$ with θ'_j.
- Hence $K_{j,(D_0)} = \hat\theta_0 K_{\mathcal{B}_j/R}$ and $\Psi_{j,(D_0)} = \hat\theta_0\Psi_{\mathcal{B}_j/R}$, and the station letters are $\mathsf{y}_{jD_0} = \sum_X w'_X\alpha^X_R = K_{\mathcal{B}_j|R}/\hat\theta_0$ and $\mathsf{y}^*_{jD_0} = \sum_X w'_X\alpha^{R\setminus X}_R = \Psi_{\mathcal{B}_j|R}/\hat\theta_0$.
- The excess 1 is the same with $\mathcal{B}_j|B$, $\mathcal{B}_j/B$ and $\hat\theta_1$.

(ii) A basis has its pattern and its room side at one excess i, so the new weights multiply to $(\hat\theta_i\,\theta'_{j,p})(\theta''_{j,X}/\hat\theta_i) = \theta_{j,p\sqcup X}$. The new θ''_j has the largest value 1 on each excess, so it is the system of the multipliers w'_X. The stations, the multipliers, the seam letters and the station letters are defined from the weights θ_j alone (28.1), so they do not change. In the normalized factorization, (i) holds with $\hat\theta_0 = \hat\theta_1 = 1$, and the four ratios are the hinge values of 19.2, read with the minors carrying the normalized weights. In a factorization with the constants $\hat\theta_0$ and $\hat\theta_1$, (i) gives the four ratios as stated. □

Proposition 28.11 (Width one is the hinge). *As stated: for a family, with θ''_j normalized on each excess, and with part (iv) for the family.*

Proof. The letters. With θ''_j of largest value 1 on the room sides of each excess, Lemma S13 gives the seam letters of the piece of the bunch and the room letters of its room, read as its partner (the paragraph after 28.4):

$$V_{jD_0} = K_{\mathcal{B}_j/R}, \quad V_{jD_1} = K_{\mathcal{B}_j|B}, \quad V^*_{jD_0} = \Psi_{\mathcal{B}_j/R}, \quad V^*_{jD_1} = \Psi_{\mathcal{B}_j|B},$$

$$L_{jD_0}=K_{\mathcal{B}_j|R},\quad L_{jD_1}=K_{\mathcal{B}_j/B},\quad L^*_{jD_0}=\Psi_{\mathcal{B}_j|R},\quad L^*_{jD_1}=\Psi_{\mathcal{B}_j/B},$$

the minors on B carrying the weights θ'_j and those on R the weights θ''_j. The hinge values of 19.2 are $\gamma^K_{j,B}=V_{jD_1}/V_{jD_0}$, $\gamma^\Psi_{j,B}=V^*_{jD_0}/V^*_{jD_1}$, $\gamma^K_{j,R}=L_{jD_0}/L_{jD_1}$ and $\gamma^\Psi_{j,R}=L^*_{jD_1}/L^*_{jD_0}$. Every letter is active and $c_j=1$, so $\kappa_B+\kappa_B^{\rm top}=\sum_j(s_j+t_j)=2\sigma$, and on the balance wall of the glue $\kappa_B+\kappa_R=2\sigma$.

The cells.

- The cell of the bunch $\mathcal{B}^+_{j,B}$ has the bases of $\mathcal{B}_j|B$ avoiding g and the $X+g$, $X\in\mathcal{B}_j/R$, through g, with the weights θ'_j (19.4). So $\mathcal{B}^+_{j,B}\setminus g=\mathcal{B}_j|B$ and $\mathcal{B}^+_{j,B}/g=\mathcal{B}_j/R$, its hinge values are $\gamma^K_{j,B}$ and $\gamma^\Psi_{j,B}$ (21.1), and its rank is $d_j(B)+1$.
- Since $d^*_j(B)=|B|-d_j(B)-1$, the hinge wall of F^+_B (23.1) is $m_B-\sum_j\big(s_jd_j(B)+t_j(|B|-d_j(B)-1)\big)=\kappa_B$.
- Likewise $\mathcal{B}^+_{j,R}\setminus g=\mathcal{B}_j|R$ and $\mathcal{B}^+_{j,R}/g=\mathcal{B}_j/B$, with the weights θ''_j and the hinge values $\gamma^K_{j,R}$ and $\gamma^\Psi_{j,R}$.
- The hinge wall of F^+_R is $m_R-\sum_j\big(s_j(r(\mathcal{B}_j|R)-1)+t_j(|R|-r(\mathcal{B}_j|R))\big)$. This is the wall κ_R of the partner, whose letters at D_0 have the degrees $r(\mathcal{B}_j|R)=e_j+1$ and $|R|-r(\mathcal{B}_j|R)=e^*_j$ (28.4).

(i) By 28.5,

$$\gamma^\rho_B=\prod_j\Big(\frac{V_{jD_1}}{V_{jD_0}}\Big)^{s_j/(2\sigma)}\Big(\frac{V^*_{jD_0}}{V^*_{jD_1}}\Big)^{t_j/(2\sigma)}=\prod_j(\gamma^K_{j,B})^{s_j/(2\sigma)}(\gamma^\Psi_{j,B})^{t_j/(2\sigma)}.$$

As $\sum_j(s_j+t_j)/(2\sigma)=1$, this is $\gamma^K_{1,B}\prod_j(\gamma^K_{j,B}/\gamma^K_{1,B})^{s_j/(2\sigma)}(\gamma^\Psi_{j,B}/\gamma^K_{1,B})^{t_j/(2\sigma)}=\gamma^K_{1,B}\,\psi(\boldsymbol{\varrho}_{F^+_B})$, the ratio vector of F^+_B being $(\gamma^K_{j,B}/\gamma^K_{1,B},\gamma^\Psi_{j,B}/\gamma^K_{1,B})_j$ (23.1). The scale form is

$$\phi^\rho_B(du)=u^{\mathbf{m}_B-\mathbf{1}}\prod_j K^{-s_j}_{\mathcal{B}_j/R}\Psi^{-t_j}_{\mathcal{B}_j|B}\big(\gamma^K_{1,B}\psi\big)^{-\kappa_B}d\omega_B(u)=\psi^{-\kappa_B}\phi_{F^+_B}(du),$$

by the base form of 23.1, whose letters are $K_{\mathcal{B}^+_{j,B}/g}=K_{\mathcal{B}_j/R}$ and $\Psi_{\mathcal{B}^+_{j,B}\setminus g}=\Psi_{\mathcal{B}_j|B}$, with the hinge wall κ_B.

(ii) By 28.5, $\varrho^\rho_{jD_0}=V_{jD_0}/V^{(0)}_j=1$ and $\varrho^{\rho*}_{jD_1}=V^*_{jD_1}/V^{*(1)}_j=1$. Further $\varrho^\rho_{jD_1}=V_{jD_1}/(V_{jD_0}\gamma^\rho_B)=\gamma^K_{j,B}/(\gamma^K_{1,B}\psi)=x_{j,K}/\psi(\mathbf{x})$ and $\varrho^{\rho*}_{jD_0}=V^*_{jD_0}/(V^*_{jD_1}\gamma^\rho_B)=x_{j,\Psi}/\psi(\mathbf{x})$, at $\mathbf{x}=\boldsymbol{\varrho}_{F^+_B}$. Write $\Phi(\mathbf{x})=\big(x_{j,K}/\psi(\mathbf{x}),\,x_{j,\Psi}/\psi(\mathbf{x})\big)_j$.

- The seam torus is the set of the points with $x_{jD_0}=x^*_{jD_1}=1$ and $\prod_j x^{s_j}_{jD_1}x^{*t_j}_{jD_0}=1$. Since $\prod_j(x_{j,K}/\psi)^{s_j}(x_{j,\Psi}/\psi)^{t_j}=\psi^{2\sigma}\psi^{-2\sigma}=1$, Φ maps $(0,\infty)^{2N-1}$ into it.
- Let a point of the torus have $x_{jD_1}=a_j$ and $x^*_{jD_0}=b_j$. The vector $\mathbf{x}$ with $x_{j,K}=a_j/a_1$ and $x_{j,\Psi}=b_j/a_1$ has $\psi(\mathbf{x})=\big(\prod_j a_j^{s_j}b_j^{t_j}\big)^{1/(2\sigma)}/a_1=1/a_1$, so $\Phi(\mathbf{x})$ is the point.
- Conversely $\Phi(\mathbf{x})$ determines $\psi(\mathbf{x})$ as the inverse of its coordinate $x_{1,K}/\psi(\mathbf{x})$, and then $\mathbf{x}$. So Φ is a bijection.

As $\boldsymbol{\varrho}^\rho_B=\Phi\circ\boldsymbol{\varrho}_{F^+_B}$ and $\phi^\rho_B=\psi(\boldsymbol{\varrho}_{F^+_B})^{-\kappa_B}\phi_{F^+_B}$, the law $(\boldsymbol{\varrho}^\rho_B)_*\phi^\rho_B$ is the image under Φ of $\psi^{-\kappa_B}$ times $(\boldsymbol{\varrho}_{F^+_B})_*\phi_{F^+_B}$.

(iii) The partner with its stand-in at $\Phi(\mathbf{x})$ (28.10(i)) has the letters

$$\sum_D x_{jD}\,\alpha_g^{i(D)}L_{jD}=K_{\mathcal{B}_j|R}+\frac{x_{j,K}}{\psi(\mathbf{x})}\,\alpha_g\,K_{\mathcal{B}_j/B},$$

$$\sum_D x^*_{jD}\,\alpha_g^{1-i(D)}L^*_{jD} = \frac{x_{j,\Psi}}{\psi(\mathbf{x})}\,\alpha_g\,\Psi_{\mathcal{B}_j|R} + \Psi_{\mathcal{B}_j/B}.$$

After $\alpha_g \mapsto \psi(\mathbf{x})\,\alpha_g$ these are $K_{\mathcal{B}_j|R} + x_{j,K}\,\alpha_g K_{\mathcal{B}_j/B}$ and $x_{j,\Psi}\,\alpha_g\Psi_{\mathcal{B}_j|R} + \Psi_{\mathcal{B}_j/B}$. These are the letters of $\mathcal{B}^+_{j,R}$ twisted at g by $x_{j,K}$ in K_j and by $x_{j,\Psi}$ in Ψ_j: by 22.1, the twist multiplies the weights in K_j of the bases through g and the weights in Ψ_j of the bases avoiding g. The mass κ_B on g turns $\alpha_g^{\kappa_B-1}d\alpha_g$ into $\psi(\mathbf{x})^{\kappa_B}\alpha_g^{\kappa_B-1}d\alpha_g$, which cancels the density of (ii). The functions of 28.8, homogeneous of degree one in the vector (y_0, y_1) of the seam letters of a letter, are $y_0\,f(\alpha_Z, y_1/y_0)$ for K_j and $y_1\,f(\alpha_Z, y_0/y_1)$ for Ψ_j, with f positive and continuous. At the seam letters they are $K_{\mathcal{B}_j/R}\,f(\alpha_Z, \gamma^K_{j,B})$ and $\Psi_{\mathcal{B}_j|B}\,f(\alpha_Z, \gamma^\Psi_{j,B})$, the factors $L_i\,f_i(\alpha_Z, \gamma_i)$ of 23.2 for F^+_B. At $\mathbf{x}_l(\alpha_g)$, after the change of variable, they are $f(\alpha_Z, x_{j,K}\alpha_g)$ and $f(\alpha_Z, x_{j,\Psi}\alpha_g)$, the factors of $\omega_{\mathbf{x}}$ in 23.2. So the two lemmas are one, read through Φ.

(iv) *The room.* Read with the reversed excesses, the station D_1 has the partner excess 0 and D_0 the partner excess 1. By 28.5 for the partner:

- its scale is

$$\prod_j \Big(\frac{L_{jD_0}}{L_{jD_1}}\Big)^{s_j/(2\sigma)}\Big(\frac{L^*_{jD_1}}{L^*_{jD_0}}\Big)^{t_j/(2\sigma)} = \prod_j (\gamma^K_{j,R})^{s_j/(2\sigma)}(\gamma^\Psi_{j,R})^{t_j/(2\sigma)} = \gamma^K_{1,R}\,\psi(\boldsymbol{\varrho}_{F^+_R}),$$

  as in (i);

- its scale form is $v^{\mathbf{m}_R-\mathbf{1}}\prod_j K^{-s_j}_{\mathcal{B}_j/B}\Psi^{-t_j}_{\mathcal{B}_j|R}(\gamma^K_{1,R}\psi)^{-\kappa_R}d\omega_R(v) = \psi^{-\kappa_R}\phi_{F^+_R}$, since the base form of F^+_R has the letters $K_{\mathcal{B}^+_{j,R}/g} = K_{\mathcal{B}_j/B}$ and $\Psi_{\mathcal{B}^+_{j,R}\setminus g} = \Psi_{\mathcal{B}_j|R}$ and the hinge wall κ_R;

- with γ_R its scale, its seam vector has $\varrho^\rho_{jD_1} = \varrho^{\rho*}_{jD_0} = 1$, $\varrho^\rho_{jD_0} = L_{jD_0}/(L_{jD_1}\gamma_R) = x'_{j,K}/\psi(\mathbf{x}')$ and $\varrho^{\rho*}_{jD_1} = L^*_{jD_1}/(L^*_{jD_0}\gamma_R) = x'_{j,\Psi}/\psi(\mathbf{x}')$ at $\mathbf{x}' = \boldsymbol{\varrho}_{F^+_R}$;

- its law follows as in (ii).

The coordinate ratios are $x_{j,\Psi}/x_{j,K} = \gamma^\Psi_{j,B}/\gamma^K_{j,B} = \varrho_{j,B}$ and $x'_{j,\Psi}/x'_{j,K} = \varrho_{j,R}$ (19.2).

The kernel. At $c_j = 1$ the configuration $t_{\mathcal{D}}$ has the column $\mathbf{e}_{K_j}$ at (j, D_0) and $\mathbf{e}_g + \mathbf{e}_{K_j}$ at (j, D_1) for K_j, and $\mathbf{e}_g + \mathbf{e}_{\Psi_j}$ at D_0 and $\mathbf{e}_{\Psi_j}$ at D_1 for Ψ_j. The display of 28.10(ii) gives

$$\Gamma(\kappa_B)\,\mathsf{Z}_{(\kappa_B,\mathbf{s},\mathbf{t});t_{\mathcal{D}}}(\mathbf{p}\circ\mathbf{p}') = \int_0^\infty v^{\kappa_B-1}\prod_j \big(p_{jD_0}p'_{jD_0} + p_{jD_1}p'_{jD_1}v\big)^{-s_j}\big(p^*_{jD_0}p'^*_{jD_0}v + p^*_{jD_1}p'^*_{jD_1}\big)^{-t_j}dv,$$

and the coordinates of (ii) and of the partner give the first line of (iv). Substitute $v = (\psi(\mathbf{x})/\psi(\mathbf{x}'))\,w$. Each factor $x_{j,K}v/\psi(\mathbf{x}) + x'_{j,K}/\psi(\mathbf{x}')$ becomes $(x_{j,K}w + x'_{j,K})/\psi(\mathbf{x}')$, and likewise for Ψ_j. Since $\sum_j(s_j+t_j) - \kappa_B = \kappa_R$, the integral is

$$\Big(\frac{\psi(\mathbf{x})}{\psi(\mathbf{x}')}\Big)^{\kappa_B}\psi(\mathbf{x}')^{\sum_j(s_j+t_j)}\int_0^\infty w^{\kappa_B-1}\prod_j(x_{j,K}w + x'_{j,K})^{-s_j}(x_{j,\Psi}w + x'_{j,\Psi})^{-t_j}dw = \psi(\mathbf{x})^{\kappa_B}\psi(\mathbf{x}')^{\kappa_R}\,P_{F_{\mathcal{H}}[(\mathbf{x},\mathbf{x}')]}\big((\kappa_B,\kappa_R);\mathbf{s},\mathbf{t}\big).$$

The last step is the period of the twisted core of 23.6(iii) with the core $\binom{\{g,g'\}}{1}$ in every table, read on the section $\alpha_{g'} = 1$ (16.2); its letters are $x_{j,K}\alpha_g + x'_{j,K}\alpha_{g'}$ and $x_{j,\Psi}\alpha_g + x'_{j,\Psi}\alpha_{g'}$ (22.1).

The reductions.

- 28.10(i) is part (iii).

- 28.10(ii): insert the laws of (ii) and of the partner. The densities $\psi(\mathbf{x})^{-\kappa_B}$ and $\psi(\mathbf{x}')^{-\kappa_R}$ cancel the factor of the kernel, and the period becomes

$$\iint P_{F_{\mathcal{H}}[(\mathbf{x},\mathbf{x}')]}\big((\kappa_B,\kappa_R);\mathbf{s},\mathbf{t}\big)\,d\big((\boldsymbol{\varrho}_{F_B^+})_*\phi_{F_B^+}\big)(\mathbf{x})\,d\big((\boldsymbol{\varrho}_{F_R^+})_*\phi_{F_R^+}\big)(\mathbf{x}').$$

  This is 23.6(iii) for the family whose table j is $\binom{\{g,g'\}}{1}\langle\mathcal{B}_{j,B}^+,\mathcal{B}_{j,R}^+\rangle$, which is the table $(\mathcal{B}_j,\theta_j)$ by 21.3(iii).

- 28.10(iii): on the pins the seam word of the piece is $\prod_j K_{\mathcal{B}_j/R}^{-a_{jD_0}}K_{\mathcal{B}_j|B}^{-a_{jD_1}}\Psi_{\mathcal{B}_j/R}^{-b_{jD_0}}\Psi_{\mathcal{B}_j|B}^{-b_{jD_1}}$. This is the word of the bunch family $F^{\mathrm{bunch}}(\mathbf{a},\mathbf{b})$ of 19.13 at the level shares $(a_j^d,a_j^r,b_j^d,b_j^r)=(a_{jD_0},a_{jD_1},b_{jD_0},b_{jD_1})$, and the room word is that of $F^{\mathrm{room}}(\mathbf{a},\mathbf{b})$.
  - The seam functions on the pins are the periods of these words (28.7), and

$$\Gamma_{\!1}^{\,2}\begin{bmatrix}a_{jD_0},\ a_{jD_1}\\ s_j\end{bmatrix}\Gamma_{\!1}^{\,2}\begin{bmatrix}b_{jD_0},\ b_{jD_1}\\ t_j\end{bmatrix}=\Gamma_{\!2}^{\,4}\begin{bmatrix}a_j^d,\ b_j^d,\ a_j^r,\ b_j^r\\ s_j,\ t_j\end{bmatrix}.$$

  - The scale pin $\sum_j(a_{jD_1}+b_{jD_0})=\kappa_B$ is the pin of 19.13.
  - In the notation of 4.1, eliminating the letter totals leaves the shares $(a_j^d,b_j^d)_j$ with the one pin $\sum_j(b_j^d-a_j^d)=\kappa_B-\sum_j s_j$, with the same power of 2π.
  - In the pair coordinates $\sigma_j^d=\frac12(a_j^d+b_j^d)$ and $\delta_j^d=\frac12(a_j^d-b_j^d)$, Lebesgue measure gains the factor 2^N, and the pin becomes $-2\sum_j\delta_j^d$, whose delta is $\frac12$ that of $\sum_j\delta_j^d$.

  So the fibre integral of 28.10(iii) is 2^{N-1} times the fibre integral in the pair coordinates, which is 19.13.

□

Remark. The constants match exactly under the normalization. In a factorization with the constants $\hat\theta_{0j},\hat\theta_{1j}$ of Lemma S13, the scale of the piece, its seam vector and its law are unchanged, since they are defined from the seam letters, while the hinge values move. Then (i) holds up to the constant factor $\prod_j(\hat\theta_{1j}/\hat\theta_{0j})^{\delta_j/\sigma}$, and the coordinate $\varrho^{\rho}_{jD_1}$ of (ii) is $(\hat\theta_{1j}/\hat\theta_{0j})\prod_l(\hat\theta_{1l}/\hat\theta_{0l})^{-\delta_l/\sigma}$ times $x_{j,K}/\psi(\mathbf{x})$. Normalizing θ_j'' on each excess removes these constants and costs no generality, by Lemma S13(ii). For one table, $\mathbf{x}=(1,\varrho_B)$ and $\mathbf{x}'=(1,\varrho_R)$. The family $F_{\mathcal{H}}[(\mathbf{x},\mathbf{x}')]$ is then the list $\binom{\{g,g'\}}{1}$ twisted in its cobasis letter by ϱ_B at g and by ϱ_R at g', and $\psi(\mathbf{x})^{\kappa_B}\psi(\mathbf{x}')^{\kappa_R}=\varrho_B^{\kappa_B t/(s+t)}\varrho_R^{\kappa_R t/(s+t)}$. So (iv) is the identity with 23.7, and the reductions are 23.9(i) and (iv) together with 19.13.

Proposition 28.15 (The Gramma of a set of pairs in the Foreman's order). *As stated, for a set of pairs with any number of parts.*

Proof. The configuration $\partial\mathfrak{R}$ of 28.13 has at the pair (C,D) the column $\mathbf{e}_C+\mathbf{e}_D$ on the kept stations, the station not kept in each part read as 0. A pair of $\mathfrak{R}_l$ has both its stations in $\mathcal{K}_l\sqcup\mathcal{D}_l$, so its column is supported on the kept stations of $\mathfrak{R}_l$, and different parts have different kept stations. By 2.5, applied to one part after another, the Gramma of $\mathfrak{R}$ is the product of the Grammas of its parts,

$$\mathsf{G}_{(\mathbf{a},\mathbf{a}');\partial\mathfrak{R}}(\mathbf{h})=\prod_{l=1}^{\nu}\mathsf{G}_{(\mathbf{a}_{\mathcal{K}_l},\mathbf{a}'_{\mathcal{D}_l});\partial\mathfrak{R}_l}(\mathbf{h}),$$

and it converges exactly when every factor does, its domain being the product of their domains. For one part the statement is the reference, proof of prop:relgrammaforeman. There the scales of $\mathcal{K}_l$ are integrated first, $\int_0^\infty x^{a_C-1}e^{-xL_C(v)}dx = \Gamma(a_C)L_C(v)^{-a_C}$. The form left on the stations of $\mathcal{D}_l$ is homogeneous of degree $|\mathbf{a}'_{\mathcal{D}_l}| - |\mathcal{D}_l| - |\mathbf{a}_{\mathcal{K}_l}| = -|\mathcal{D}_l|$, so its integral over a chart is its integral over $\Delta_{\mathcal{D}_l}$ (16.2), and the convergence criterion is 25.2. Multiplying over the parts gives the statement. □

Proposition 28.16 (Closing the Gramma of a set of pairs). *As stated: any number of parts, and (ii) at real and complex loads.*

Proof. (i) On each part the reference's proof (proof of prop:relgrammaclose(i)) applies on the simplex $\Delta_{\mathcal{D}_l}$. On its interior $0 \le \bar{L}_C < 1$ almost everywhere, and $L_C^{-a_C} = M_C^{-a_C}\sum_n \frac{(a_C)_n}{n!}\bar{L}_C^{\,n}$ with nonnegative terms. On the simplex $\bar{L}_C$ is a linear function with nonnegative coefficients, and Tonelli's theorem with 3.11 gives the series. By 28.15 the Gramma is $\prod_C \Gamma(a_C)$ times the product of these integrals over the parts.

(ii) The exchange relation of 2.4(ii) holds at every index of the domain, real or complex.

- At a kept station of $\mathcal{K}$ or of $\mathcal{D}$ it is the stated relation, the column of (C, D) being $\mathbf{e}_C + \mathbf{e}_D$ with the coefficient h_{CD}.
- At the station not kept of a part it is the sum of the relations at the stations of $\mathcal{K}$ of that part less those at its other stations of $\mathcal{D}$, the totals of a part being equal (the reference, proof of prop:relgrammaclose(ii)).
- A shifted load $(\mathbf{a} + \mathbf{e}_C, \mathbf{a}' + \mathbf{e}_{D'})$ with $(C, D') \in \mathfrak{R}$ keeps the totals of every part equal, since C and D' lie in one part, and it lies in the domain with $(\mathbf{a}, \mathbf{a}')$ (2.4).

Neither (i) nor (ii) uses one part, and (ii) does not use real loads.

(iii) concerns one part and is the reference, proof of prop:relgrammaclose(iii). □

Theorem 28.19 (The law is what a piece retains, at every width). *As stated; the plain tinkers suffice under the stated condition on the tables with both letters active.*

Proof. The equivalence of (a)–(d) is the reference, proof of thm:retainwidth. Its step (c)⇒(d) reads as follows in the notation of 4.1.

The step (c)⇒(d). Let V be the real space of the directions of the pins of the seam (28.7): the vectors $\boldsymbol{\vartheta} = (\vartheta_{jD}, \vartheta^*_{jD})_{j,D}$, one coordinate for each coordinate of the seam vector, with

$$\sum_D \vartheta_{jD} = 0 \text{ for every active } K_j, \qquad \sum_D \vartheta^*_{jD} = 0 \text{ for every active } \Psi_j,$$
$$\sum_{j,D} \big(i(D)\vartheta_{jD} + (c_j - i(D))\vartheta^*_{jD}\big) = 0.$$

For a tinker $\mathbf{v}$ of $\mathcal{Y}_0$ with the logarithms $\boldsymbol{\ell} = \log \mathbf{v}$, the seam word of $\mathcal{Y}_{0,\mathbf{v}}$ is $\mathbf{v}^{-(\mathbf{a},\mathbf{b})}$ times that of $\mathcal{Y}_0$. So, by 28.7 and by 28.10(iii) on the contour through $\mathbf{c}$,

$$e^{\langle \mathbf{c}, \boldsymbol{\ell}\rangle}\, P_{\mathcal{X}\sqcup\mathcal{Y}_{0,\mathbf{v}}} = (2\pi)^{-n_{\mathcal{D}}} \int_V e^{-i\langle \boldsymbol{\ell}, \boldsymbol{\vartheta}\rangle}\, f(\boldsymbol{\vartheta})\, d\boldsymbol{\vartheta},$$

where $f(\boldsymbol{\vartheta})$ is the product of the stacked Gammas of 28.10(iii) and of the seam functions of $\mathcal{X}$ and of $\mathcal{Y}_0$ at $\mathbf{c} + i\boldsymbol{\vartheta}$. The stacked Gammas have no zero, and f is continuous and integrable on V (the reference, proof of thm:retainwidth). The proof uses (c) only to know the Fourier transform

of f at every point of the dual of V; then f is determined. The rest is unchanged: the stacked Gammas have no zero, the seam function of $\mathcal{Y}_0$ is positive at $\mathbf{c}$, the identity theorem applies, and the projection is injective on the seam torus.

The plain tinkers. Their logarithms form the space Λ of the $\boldsymbol{\ell}$ with $\ell_{jD} = \ell^*_{jD}$ for every table j with both letters active (28.18). A table with one active letter has one coordinate for each station, and on it a plain tinker is a general one. The restrictions to V of the functionals $\boldsymbol{\vartheta} \mapsto \langle \boldsymbol{\ell}, \boldsymbol{\vartheta} \rangle$, $\boldsymbol{\ell} \in \Lambda$, exhaust the dual of V exactly when no nonzero $\boldsymbol{\vartheta} \in V$ is orthogonal to Λ.

No orthogonal vector. Let $\boldsymbol{\vartheta} \in V$ be orthogonal to Λ.

- Then $\vartheta_{jD} = 0$ in a table with only K_j active, $\vartheta^*_{jD} = 0$ in a table with only Ψ_j active, and $\vartheta^*_{jD} = -\vartheta_{jD}$ in a table with both letters active.
- The letter totals give $\sum_D \vartheta_{jD} = 0$ in every table with both letters active. The scale pin becomes $\sum_{j,D} \big(2i(D) - c_j\big)\vartheta_{jD} = 0$, the sum running over the tables with both letters active.
- A table with $|\mathcal{D}_j| = 1$ has $\vartheta_{jD} = 0$ by its total.
- The exceptional table has $c_j \geq 1$, and $\mathcal{D}_{j,0}$ and $\mathcal{D}_{j,c_j}$ are nonempty (28.4), so its two stations D' and D'' have the excesses 0 and c_j. Its total gives $\vartheta_{jD'} = -\vartheta_{jD''} = \tau$, and the scale pin reads $-c_j\tau - c_j\tau = 0$, so $\tau = 0$.

Hence $\boldsymbol{\vartheta} = 0$, and the plain tinkers suffice in (c). □

Remark. In general, let J_2 be the tables with both letters active. The orthogonal of Λ in V has the dimension $\sum_{j \in J_2}(|\mathcal{D}_j| - 1)$, less one when some table of J_2 has positive width. Indeed, the vectors with $\sum_D \vartheta_{jD} = 0$ on the tables of J_2 and zero elsewhere form a space of the first dimension, and on it the scale pin $\sum_{j,D}(2i(D) - c_j)\vartheta_{jD}$ vanishes identically exactly when every table of J_2 has width zero. With every letter active and some table of positive width, $n_{\mathcal{D}} = 2|\mathcal{D}| - 2N - 1$ and the orthogonal has the dimension $|\mathcal{D}| - N - 1$, so the plain tinkers of one partner move $|\mathcal{D}| - N$ of the directions of the seam torus, as the paragraph after the theorem says.

Lemma 28.23 (Partners on one mark see a point mass). *As stated.*

Proof. The one-mark piece. On one mark the seam letters have $d_j = d^*_j = 0$, the wall is the mass κ, and by the relations of the seam torus the excess sums are $V_j^{(0)} = \sum_{D \in \mathcal{D}_{j,0}} x_{jD} = 1$, $V_j^{*(c_j)} = 1$, $V_j^{(c_j)} = \alpha_g^{c_j} \sum_{D \in \mathcal{D}_{j,c_j}} x_{jD}$ and $V_j^{*(0)} = \alpha_g^{c_j} \sum_{D \in \mathcal{D}_{j,0}} x^*_{jD}$. So the scale and the seam vector of 28.5 are

$$\alpha_g \Big(\prod_j \Big(\sum_{D \in \mathcal{D}_{j,c_j}} x_{jD} \Big)^{s_j} \Big(\sum_{D \in \mathcal{D}_{j,0}} x^*_{jD} \Big)^{t_j} \Big)^{1/w} = \alpha_g,$$

$$\Big(\frac{x_{jD}\, \alpha_g^{i(D)}}{\alpha_g^{i(D)}},\ \frac{x^*_{jD}\, \alpha_g^{c_j - i(D)}}{\alpha_g^{c_j - i(D)}} \Big)_{j,D} = \mathbf{x},$$

and the scale form on the one point of $\Delta_{\{g\}}$ has the mass 1: the law is $\delta_{\mathbf{x}}$, and the station transform is the kernel at $\mathbf{x}$ (28.21). In the chart $\alpha_b = 1$ the period of the glue of $\mathcal{X}$ with the partner on b is $\int_{(0,\infty)^B} \alpha^{\mathbf{m}_B - \mathbf{1}} \prod_j (\sum_D p_{jD} V_{jD})^{-s_j} (\sum_D p^*_{jD} V^*_{jD})^{-t_j} d\alpha$, the second expression of 28.21; the partner has the degrees $e_j = e^*_j = 0$, the wall $w - \kappa$, and its room letters are those of the partner with the coefficients 1 tinkered by $\mathbf{p}$ (28.18).

Coordinates. Index the coordinates of the seam vector by the pairs of an active letter l and a station of its table, $n_{\mathcal{X}}$ of them; write $\mathbf{p} = e^{\mathbf{P}}$ with $\mathbf{P} \in \mathbb{R}^{n_{\mathcal{X}}}$, and pair shares $(\mathbf{a}, \mathbf{b}) \in \mathbb{R}^{n_{\mathcal{X}}}$, one for each coordinate, with $\mathbf{P}$ by $\langle (\mathbf{a}, \mathbf{b}), \mathbf{P} \rangle$. Let $\mathbf{u}_l$ be the indicator of the coordinates of the letter

l, U' the span of the $\mathbf{u}_l$, $\mathbf{u}_0$ the vector with the entries $i(D)$ at the coordinates of the letters K_j and $c_j - i(D)$ at those of the letters Ψ_j, and $U = U' + \mathbb{R}\mathbf{u}_0$. Since $w > 0$ some active letter has $c_j > 0$, and on its coordinates $\mathbf{u}_0$ takes the values 0 and c_j at the excesses 0 and c_j, which have stations; so $\mathbf{u}_0 \notin U'$. The pins of the seam (28.7) are $\langle (\mathbf{a},\mathbf{b}), \mathbf{u}_l\rangle$ equal to the exponent of l and $\langle (\mathbf{a},\mathbf{b}), \mathbf{u}_0\rangle = \kappa$; let $\mathcal{A}$ be the set of the shares with positive coordinates on the pins. For one letter of width $c_j > 0$ and exponent s, the sums $\sum_D i(D) a_{jD}$ over positive shares with $\sum_D a_{jD} = s$ fill $(0, sc_j)$, and they are 0 at width zero; so on the pins the scale pin takes every value in $(0, w)$, and $\mathcal{A}$ is not empty, open in the affine space of the pins, whose direction space is $V = U^\perp$.

The station transform opens the seam function. Fix $(\mathbf{a},\mathbf{b}) \in \mathcal{A}$ and put $f(\mathbf{P}) = e^{\langle (\mathbf{a},\mathbf{b}),\mathbf{P}\rangle}\, \Gamma(\kappa) \mathsf{Z}_{(\kappa,\mathbf{s},\mathbf{t});t_{\mathcal{D}}}(e^{\mathbf{P}})$. By the kernel of 28.10(ii) with $v = e^\tau$,

$$f(\mathbf{P}) = \int_{\mathbb{R}} g(\mathbf{P} + \tau\mathbf{u}_0)\, d\tau, \qquad g(\mathbf{Q}) = e^{\langle (\mathbf{a},\mathbf{b}),\mathbf{Q}\rangle} \prod_{j:\, s_j>0} \Big(\sum_D e^{Q_{jD}}\Big)^{-s_j} \prod_{j:\, t_j>0} \Big(\sum_D e^{Q^*_{jD}}\Big)^{-t_j},$$

using $\langle (\mathbf{a},\mathbf{b}), \mathbf{u}_0\rangle = \kappa$. Translation by $\mathbf{u}_l$ multiplies the letter l by e^λ and the exponential by $e^{\lambda s}$, s its exponent: g is invariant under U', and f under U, a translation by $\mathbf{u}_0$ being absorbed by τ. Let W be a linear complement of U and W' the subspace on which the coordinate of one chosen station D_l of every active letter vanishes, a complement of U'. Since $\mathbf{u}_0 \notin U'$, $(\mathbf{P}, \tau) \mapsto \mathbf{P} + \tau\mathbf{u}_0$ is a linear isomorphism of $W \times \mathbb{R}$ onto $\mathbb{R}^{n_{\mathcal{X}}}/U' \cong W'$, and by Tonelli and the invariance of g

$$\int_W f\, d\mathbf{P} = c_W \int_{W'} g = c_W \prod_{j:\, s_j>0} \Gamma_{|\mathcal{D}_j|}\begin{bmatrix}\mathbf{a}_j\\ s_j\end{bmatrix} \prod_{j:\, t_j>0} \Gamma_{|\mathcal{D}_j|}\begin{bmatrix}\mathbf{b}_j\\ t_j\end{bmatrix} =: \beta(\mathbf{a},\mathbf{b}) \in (0,\infty),$$

with $c_W > 0$ fixed by W, W' and their Lebesgue measures. On W' the integral factors over the letters; for a letter K_j, with $y_D = e^{Q_{jD}}$ and $a_{jD_l} = s_j - \sum_{D\neq D_l} a_{jD} > 0$, it is $\int_{(0,\infty)^{\mathcal{D}_j\setminus D_l}} \prod_{D\neq D_l} y_D^{a_{jD}-1} \big(1 + \sum_{D\neq D_l} y_D\big)^{-s_j} d\mathbf{y}$, which is the stacked Gamma, as $(1+|\mathbf{y}|)^{-s_j} = \Gamma(s_j)^{-1} \int_0^\infty x^{s_j-1} e^{-x(1+|\mathbf{y}|)} dx$ and Tonelli integrate it to $\prod_D \Gamma(a_{jD})/\Gamma(s_j)$; likewise for a letter Ψ_j. For $\mathbf{x}$ on the seam torus and $\mathbf{X} = \log \mathbf{x}$, $e^{\langle (\mathbf{a},\mathbf{b}),\mathbf{P}\rangle} \Gamma(\kappa) \mathsf{Z}(\mathbf{x} \circ e^{\mathbf{P}}) = e^{-\langle (\mathbf{a},\mathbf{b}),\mathbf{X}\rangle} f(\mathbf{P}+\mathbf{X})$, and $\int_W f(\mathbf{P}+\mathbf{X})\, d\mathbf{P} = \int_W f\, d\mathbf{P}$ by the invariance of f under U, Lebesgue measure on W being invariant under translation. By the first expression of 28.21 and Tonelli,

$$\int_W e^{\langle (\mathbf{a},\mathbf{b}),\mathbf{P}\rangle}\, \mathcal{I}_{\mathcal{X}}(e^{\mathbf{P}})\, d\mathbf{P} = \beta(\mathbf{a},\mathbf{b}) \int \mathbf{x}^{-(\mathbf{a},\mathbf{b})}\, d\mu(\mathbf{x}),$$

μ the law of $\mathcal{X}$. The hypothesis makes the left side $c\,\beta(\mathbf{a},\mathbf{b})\, \mathbf{x}_0^{-(\mathbf{a},\mathbf{b})}$, so $\int \mathbf{x}^{-(\mathbf{a},\mathbf{b})} d\mu = c\, \mathbf{x}_0^{-(\mathbf{a},\mathbf{b})}$ for every $(\mathbf{a},\mathbf{b}) \in \mathcal{A}$: the seam function is finite on all of $\mathcal{A}$.

A point mass. Fix $(\mathbf{a}_0,\mathbf{b}_0) \in \mathcal{A}$ and let $\nu = \mathbf{x}^{-(\mathbf{a}_0,\mathbf{b}_0)}\mu$, a finite measure of the total mass $C = c\, \mathbf{x}_0^{-(\mathbf{a}_0,\mathbf{b}_0)}$. For $\boldsymbol{\delta} \in V$ near 0, $(\mathbf{a}_0,\mathbf{b}_0) \pm \boldsymbol{\delta} \in \mathcal{A}$, and so $\int (\mathbf{x}/\mathbf{x}_0)^{\mp\boldsymbol{\delta}} d\nu = C$ and

$$\int \Big((\mathbf{x}/\mathbf{x}_0)^{\boldsymbol{\delta}/2} - (\mathbf{x}/\mathbf{x}_0)^{-\boldsymbol{\delta}/2} \Big)^2 d\nu(\mathbf{x}) = C - 2C + C = 0.$$

So $\langle \log \mathbf{x} - \log \mathbf{x}_0, \boldsymbol{\delta}\rangle = 0$ for ν-almost every $\mathbf{x}$, for every $\boldsymbol{\delta}$ of a basis of V, and $\log \mathbf{x} - \log \mathbf{x}_0 \in V^\perp = U$ for μ-almost every $\mathbf{x}$, μ and ν having the same null sets. Two points $\mathbf{x}, \mathbf{x}'$ of the seam torus with $\log \mathbf{x} - \log \mathbf{x}' \in U$ are equal: $\log x_{jD} - \log x'_{jD} = \lambda_j + \lambda i(D)$ and $\log x^*_{jD} - \log x'^*_{jD} = \lambda^*_j + \lambda(c_j - i(D))$; the relations at the excess 0 of the letters K_j and at the excess c_j of the letters Ψ_j give $\lambda_j = \lambda^*_j = 0$, and then the product relation gives $e^{\lambda w} = 1$, so $\lambda = 0$. Hence μ is carried by $\mathbf{x}_0$, and $\mu = c\, \delta_{\mathbf{x}_0}$. □

Theorem 28.24 (A bunch is stored on one mark exactly at width one). *As stated, the clause at width one read with the normalization of 28.11.*

Proof. Everything except the clause at width one is the reference, proof of thm:storeone. At width one with factoring weights, Lemma S13(i) writes the letters of the partner with its stand-in at a seam point $\mathbf{x}$, where $x_{jD_0} = x^*_{jD_1} = 1$, as

$$\frac{1}{\hat\theta_0}\Big(K_{\mathcal{B}_j|R} + \frac{\hat\theta_0}{\hat\theta_1}\, x_{jD_1}\, \alpha_g\, K_{\mathcal{B}_j/B}\Big), \qquad \frac{1}{\hat\theta_1}\Big(\frac{\hat\theta_1}{\hat\theta_0}\, x^*_{jD_0}\, \alpha_g\, \Psi_{\mathcal{B}_j|R} + \Psi_{\mathcal{B}_j/B}\Big),$$

the constants $\hat\theta_0, \hat\theta_1$ being those of table j. Under the normalization of 28.11 the constants are 1. The letters are then those of $\mathcal{B}^+_{j,R}$ twisted at g by x_{jD_1} in K_j and by $x^*_{jD_0}$ in Ψ_j (19.4, 22.1). At the seam point of a value $\mathbf{y}$ of the ratio vector of F^+_B these twists are $y_{j,K}/\psi(\mathbf{y})$ and $y_{j,\Psi}/\psi(\mathbf{y})$ (28.11(ii)), and the change of variable $\alpha_g \mapsto \psi(\mathbf{y})\alpha_g$ of 28.11(iii) turns them into the twist by $\mathbf{y}$, as stated. Without the normalization the two letters carry the constant factors $1/\hat\theta_0$ and $1/\hat\theta_1$ and the twists $(\hat\theta_0/\hat\theta_1)x_{jD_1}$ and $(\hat\theta_1/\hat\theta_0)x^*_{jD_0}$. The last sentence of the clause is 28.11(i)–(iii). □

Theorem 28.25 (A point mass is a pinned set). *As stated.*

Proof. The walls. On the balance wall $\kappa_S + \kappa_{S'} = 2\sum_j \sigma_j c_j(S) = w$ (8.16), and both walls are positive; so $w > 0$ and $0 < \kappa_S < w$. By the paragraph after 28.4, S is a piece with the seam letters $V_{jD} = K_{j,(D)}$ and $V^*_{jD} = \Psi_{j,(D)}$ of the stations D of its room, S' is a partner, and their glue is F (28.2(iii)); the wall of the piece is κ_S and its top wall $w - \kappa_S = \kappa_{S'}$.

(i) and the seam vector. The scale form has a positive continuous density on the open simplex Δ_S, the excess sums and the scale being positive there, and the seam vector is continuous. So the law is carried by one point exactly when the seam vector is constant, $\mathbf{x}_0$ say, and then it is $c\,\delta_{\mathbf{x}_0}$ with $c = \int_{\Delta_S} \phi^\rho_S > 0$. By 28.10(i) with the partner S', $P_F = c\, P_{S'(\mathbf{x}_0)}$ in $[0,\infty]$; P_F is finite and $P_{S'(\mathbf{x}_0)} > 0$, so c and $P_{S'(\mathbf{x}_0)}$ are finite.

(ii)⇒(i). An active table of width zero at S with its weights factoring across S and S' has one station of room sides (28.3(i)), whose coordinates of the seam vector are $V_{jD}/V^{(0)}_j = 1$ and $V^*_{jD}/V^{*(c_j)}_j = 1$. An active table of width one with factoring weights has the stations D_0 and D_1 and the seam letters $K_{\mathcal{B}_j/S'}, K_{\mathcal{B}_j|S}$ and $\Psi_{\mathcal{B}_j/S'}, \Psi_{\mathcal{B}_j|S}$ (28.3(ii), the paragraph after 28.5), so its coordinates are 1, $\gamma^K_{j,S}/\gamma^\rho_S$, $\gamma^\Psi_{j,S}/\gamma^\rho_S$ and 1, the hinge values read at the factorization that normalizes the multipliers. Under (ii) the scale is $\gamma^\rho_S = \prod_j (c_j\gamma)^{s_j/w}(c^*_j\gamma)^{t_j/w} = C\gamma$, the product over the tables of width one with $C = \prod_j c_j^{s_j/w} c_j^{*\,t_j/w}$, and every coordinate is a constant: c_j/C, c^*_j/C or 1.

(i)⇒(ii). Let the seam vector be the constant $\mathbf{x}_0$. For every active letter K_j, $V_{jD} = x_{0,jD} V^{(0)}_j (\gamma^\rho_S)^{i(D)}$, and by the room-station factorization (28.2(iii))

$$K_j = \sum_D V_{jD}\, \mathsf{y}_{jD} = V^{(0)}_j(\alpha_S) \sum_D x_{0,jD}\, \gamma^\rho_S(\alpha_S)^{i(D)}\, \mathsf{y}_{jD}(\alpha_{S'}),$$

so K_j reads S through the one function γ^ρ_S, positive and homogeneous of degree one, with $V^{(0)}_j$ positive and homogeneous: by 19.6, $c_j(S) \le 1$. Likewise for every active letter Ψ_j, with $V^{*(c_j)}_j$ and $(\gamma^\rho_S)^{c_j - i(D)}$. Two stations $D \ne D'$ of one excess would have proportional seam letters, $V_{jD}/V_{jD'} = x_{0,jD}/x_{0,jD'}$ (or the same with V^*), so proportional room children, against 28.1(i); so every excess of every active table has one station of room sides, hence one station of patterns (28.3), and is one rectangle, which at the extreme excesses, and so at widths zero and one, means that the weights

factor across S and S' (28.3(i),(ii)). At width one the coordinates above are constant, so the active hinge values are positive multiples of γ_S^ρ: they read S alike, with $\gamma = \gamma_S^\rho$.

(i)⇒(iii)⇒(iv)⇒(i). The first is 28.10(i) with the law $c\,\delta_{\mathbf{x}_0}$. For the second take the partner on one mark b with the room letters $p_{jD}\alpha_b^{c_j - i(D)}$ and $p_{jD}^*\alpha_b^{i(D)}$ and the mass $w - \kappa_S$: the period of its glue with S is the station transform at $\mathbf{p}$ (28.23), and the partner with its stand-in at $\mathbf{x}_0$ is the glue of the one-mark piece at $\mathbf{x}_0$ with it, whose period is the kernel $\Gamma(\kappa_S)\mathsf{Z}_{(\kappa_S,\mathbf{s},\mathbf{t});t_\mathcal{D}}(\mathbf{x}_0 \circ \mathbf{p})$ (28.10(ii)). The third is 28.23.

Lists. With the weights 1 the seam letters are the letters themselves and the multipliers are 1 (28.1). Let two active hinge values of tables of width one be proportional, $\gamma_{j,S}^K = \mu\,\gamma_{j',S}^\Psi$ say, that is $K_{\mathcal{B}_j|S}\Psi_{\mathcal{B}_{j'}|S} = \mu\,K_{\mathcal{B}_j/S'}\Psi_{\mathcal{B}_{j'}/S'}$ (19.2). Along a maximal chain of subsets of S the terms of least degree of each of these four letters, at every set of the chain at once, form one monomial with the coefficient 1 (12.20); for a product of two polynomials with nonnegative coefficients the least degrees add and the terms of least degree are the products of those of the factors, so the two sides have such terms $1 \cdot \alpha^{\mathbf{a}}$ and $\mu\,\alpha^{\mathbf{a}'}$, and $\mu = 1$. The other pairs of letters are alike. So reading alike is equality, every c_j and c_j^* is 1, $C = 1$, and $\mathbf{x}_0 = \mathbf{1}$.

One list. With both letters active, $w = (s+t)c(S) > 0$, so pinned means $c(S) = 1$ and γ_S^K and γ_S^Ψ equal, by the above, that is $\varrho_S = 1$, which is $\mathbf{E}_{\mathcal{B}|S} = \mathbf{E}_{\mathcal{B}/S'}$ (19.2). The cell of the bunch $\mathcal{B}_S^+$ is a list with the hinge minors $\mathcal{B}|S$ and $\mathcal{B}/S'$ (19.4) and the ratio ϱ_S (21.1). □

Corollary 28.26 (Which sets split off). *As stated.*

Proof. (i) A pinned set has width at most one in every active table; apply 28.25. (ii) A prime table is connected, so a set with at least two marks on each side has positive width (7.10), and it has no bunch of width one with two marks on each side (23.16); so such a set has width at least two, and (i) applies. (iii) The set $S = \mathcal{E} \setminus \{e\}$ has the width $c(\{e\}) = r(\{e\}) - d(\{e\}) = 1$ (7.13), and one letter is active, so S is pinned with $\gamma = \gamma_S^K$, and it splits off. At $(s,0)$, $d(\{e\}) = 0$ gives $\kappa_{\{e\}} = m_e$ and $\kappa_S = s - m_e$, as $\kappa_S + \kappa_{\{e\}} = s$ (8.16). 19.14 with the bunch S and the room $\{e\}$, at the level shares $(s - \kappa_S, 0, \kappa_S, 0)$, gives the Beta corner $\Gamma_{\begin{smallmatrix}2\\1\end{smallmatrix}}\begin{bmatrix} s - m_e, & m_e \\ & s \end{bmatrix}$ times the period of the bunch family, the tables $\mathcal{B}/\{e\} = \mathcal{B}/e$ at $(m_e, 0)$ and $\mathcal{B}|S = \mathcal{B} \setminus e$ at $(s - m_e, 0)$ (7.5), times the period of the room family on one mark, which is 1. At $(0,t)$, $d^*(\{e\}) = 0$ gives $\kappa_{\{e\}} = m_e$, $\kappa_S = t - m_e$, and the level shares $(0, \kappa_S, 0, t - \kappa_S)$ give the stated family. (iv) $S = \mathcal{E} \setminus \{e\}$ has width one and $|S| \geq 2$, and its hinge minors are $\mathcal{B}|S = \mathcal{B} \setminus e$ and $\mathcal{B}/\{e\} = \mathcal{B}/e$; apply the last part of 28.25. □

50.29 Chapter 29: composing bunches

Theorem 29.6 (Two transforms of a law, and their rules). *As stated; the first rule of (iii) holds at any number of sub-pieces.*

Proof. Parts (i), (ii) and (iv), and the second and third rules of (iii), are the reference, proof of thm:lawreadings. For the first rule:

- Let $S_1, \ldots, S_k$ be as in 29.2, and $\mathbf{p}$ a point with positive coordinates, one for each coordinate of the seam vector of S.
- By 28.21, $\mathcal{I}_S(\mathbf{p}) = \int H\,d\lambda_S$, with the law $\lambda_S = (\boldsymbol{\varrho}_S^\rho)_*\phi_S^\rho$ and the Borel function $H(\mathbf{z}) = \Gamma(\kappa_S)\,\mathsf{Z}_{(\kappa_S,\mathbf{s},\mathbf{t});t_\mathcal{D}}(\mathbf{z} \circ \mathbf{p}) \geq 0$, $\mathcal{D}$ being the stations of room sides of S.
- 29.2(ii) gives $\int H\,d\lambda_S = \int \big(\int H\,d\lambda_{\mathbf{x}}\big) \prod_l d\lambda_{S_l}(\mathbf{x}_l)$, with $\lambda_{\mathbf{x}}$ the law of the node $S^{(\mathbf{x}_1,\ldots,\mathbf{x}_k)}$.

- The node is a piece with the stations $\mathcal{D}$, the exponents of the family and the wall κ_S (29.2(ii)), so by the same definition $\int H\, d\lambda_{\mathbf{x}} = \mathcal{I}_{S^{(\mathbf{x}_1,\dots,\mathbf{x}_k)}}(\mathbf{p})$.

This is the reference's argument for one sub-piece, which does not use $k = 1$. The second and third rules use the transfer matrices from one sub-piece: 29.2(i) gives linearity in the seam letters of each S_l separately, with coefficients that depend on the marks of the other sub-pieces. □

Theorem 29.8 (Cyclic chains). *As stated: (i) holds for a family, and in (ii) each letter is opened over the starting states at which its term is not zero.*

Proof. (i) Fix a table j.

- By 21.14(ii), the bases of table j are the unions of the unpaired parts of the choices of one basis in every cell $\mathcal{A}_{j,i}$ that occupy exactly one hinge of every pair. Its weight in each letter at a basis is the sum, over the choices that give it, of the products of the weights chosen.
- A pair of I_{i-1} occupied on the side of the cell $i-1$ is free on the side of the cell i, and conversely. So, with $J_i \subseteq I_i$ the pairs occupied on the side of the cell i, the basis chosen in $\mathcal{A}_{j,i}$ occupies the hinges $(I_{i-1} \setminus J_{i-1}) \sqcup J_i$.
- Its part $X_i \subseteq B_i$ is a basis of the child of the bunch of its hinges at that pattern. With their weights, these choices sum to the channel $K_{\mathcal{A}_{j,i},((I_{i-1}\setminus J_{i-1})\sqcup J_i)}(\alpha_{B_i})$ (21.13).
- A basis $\bigsqcup_i X_i$ leaves the cobasis $\bigsqcup_i (B_i \setminus X_i)$, so Ψ_j is summed the same way with the channels of Ψ.
- Summing over the sequences $(J_0, \dots, J_{k-1})$, $J_k = J_0$, gives $K_j = \operatorname{tr} \prod_i \mathbf{M}_{K_j,i}$ and $\Psi_j = \operatorname{tr} \prod_i \mathbf{M}_{\Psi_j,i}$. The entries are polynomials in α_{B_i} with nonnegative coefficients and no ε, which is the top layer 0.
- The pairs are named alike in every table, so the sets of states $\mathcal{J}_i = \{J :\ J \subseteq I_i\}$ serve every letter, as 29.7 asks.

This is the reference's proof (proof of thm:cyclicchain(i)) applied table by table.

(ii) and (iii) are the reference, proof of thm:cyclicchain. In (ii), L is the sum over the starting states J of the terms $\mathbf{e}_{(J,0)}^{\mathsf{T}} \prod_i \widetilde{\mathbf{M}}_{L,i}\, \mathbf{e}_{(J,h)}$, each a sum over the paths from $(J,0)$ to (J,h) of products of entries with nonnegative coefficients. 4.4 opens a sum of positive terms, one share for each. A starting state whose term vanishes, the state of no path, therefore carries no share and no flow. □

50.30 Chapter 30: Foreman fusion

The proofs use the rank function of a table, $r(Y) = \max_T |T \cap Y|$ (Definition 7.4), through its standard properties: $r(\varnothing) = 0$, $r(Y) \le r(Y+e) \le r(Y)+1$ and $r(Y \cup Y') + r(Y \cap Y') \le r(Y) + r(Y')$; conversely a function on the subsets of a finite set with these three properties is the rank function of the table whose bases are the sets Y with $|Y| = r(Y)$ equal to the value at the whole set (the rank axioms, which hold for the bases of Definition 7.1 by the arena property, the exchange property of the bases). A set is *closed* when it is maximal for its rank, that is when adding any mark raises its rank; the *closure* of Y is the set of the marks whose addition does not raise the rank of Y, it is closed, and it lies in every closed set that contains Y. A mark $e \notin Y$ lies in the closure of Y exactly when some circuit C has $e \in C \subseteq Y + e$: a basis I of Y with $I + e$ dependent contains, with e, a circuit through e, and a circuit C through e inside $Y + e$ puts e in the closure of $C - e$. For a minor contracting an independent set C and deleting D, the rank of a set Y of the remaining

marks is $r(Y \cup C) - r(C)$ (Definition 7.5). The dual rank function is $r^*(Y) = |Y| + r(\mathcal{E} \setminus Y) - r$ (Definition 7.12), and $d(Y) = |Y| - r^*(Y)$.

Definition 30.1 (Quotients; lifts; the level cell of a pair). As stated.

Proof. That the lifts and the level cell are tables is Proposition 30.2(ii) and (iii). For a bunch B with the room R, $\mathcal{B}/R$ is a quotient of $\mathcal{B}|B$: for $X \subseteq Y \subseteq B$, submodularity gives $r(Y) - r(X) \geq r(Y \cup R) - r(X \cup R)$, which is the inequality of Proposition 30.2(i) for the rank functions $r(\cdot)$ of $\mathcal{B}|B$ and $r(\cdot \cup R) - r(R)$ of $\mathcal{B}/R$. The independent sets of $\mathcal{L}_j(\mathcal{B}|B, \mathcal{B}/R)$ are the X with $|X| \leq r(X)$ and $|X| \leq r_{\mathcal{B}/R}(X) + j$, the independent sets of Proposition 12.17(ii) for $i = j$, so the two lifts are one table, and the level cells of Definition 30.1 and Lemma 28.27 have the same bases. Level form at G is Proposition 14.12: a transposition of two marks of G fixes X and $|Q|$. □

Proposition 30.2 (The level cell of a pair). *As stated.*

Proof. (i) Let the inequality hold, A be closed in $\mathcal{N}$ and $e \notin A$. Then $r_{\mathcal{N}}(A + e) = r_{\mathcal{N}}(A) + 1$, the inequality at $X = A$, $Y = A + e$ gives $r_{\mathcal{M}}(A + e) = r_{\mathcal{M}}(A) + 1$, and A is closed in $\mathcal{M}$. Conversely, let every closed set of $\mathcal{N}$ be closed in $\mathcal{M}$. Along a chain from X to Y adding one mark at a time it suffices to take $Y = X + e$. If $r_{\mathcal{N}}(X + e) = r_{\mathcal{N}}(X)$ the inequality holds, $r_{\mathcal{M}}$ being monotone. Otherwise e is not in the closure A of X in $\mathcal{N}$; A is closed in $\mathcal{M}$ and contains X, so the closure of X in $\mathcal{M}$ lies in A and avoids e, and $r_{\mathcal{M}}(X + e) = r_{\mathcal{M}}(X) + 1$. At $X = \varnothing$, $Y = \mathcal{E}$ the inequality gives $c \geq 0$; at $X = \varnothing$ it gives $r_{\mathcal{M}}(Y) \geq r_{\mathcal{N}}(Y)$, so a set independent in $\mathcal{N}$ is independent in $\mathcal{M}$; at $Y = \mathcal{E}$ it gives $r_{\mathcal{N}}(\mathcal{E}) - r_{\mathcal{N}}(X) \leq r_{\mathcal{M}}(\mathcal{E}) - r_{\mathcal{M}}(X)$, so a set spanning $\mathcal{M}$ spans $\mathcal{N}$; and two such inequalities add.

(ii) Put $f_1(Y \sqcup P) = r_{\mathcal{M}}(Y) + |P|$ and $f_2(Y \sqcup P) = r_{\mathcal{N}}(Y) + c$. Each is monotone, rises by at most one when a mark is added, and is submodular, being a rank function plus a function that is modular; $f_1(\varnothing) = 0 \leq c = f_2(\varnothing)$; and $f_1 - f_2 = r_{\mathcal{M}}(Y) - r_{\mathcal{N}}(Y) + |P| - c$ is nondecreasing under inclusion by (i). The minimum of two submodular functions with a nondecreasing difference is submodular: for sets Z, Z' the cases where one function attains the minimum at both are its own submodularity, and if $\min(Z) = f_1(Z)$ and $\min(Z') = f_2(Z')$, then

$$f_1(Z) + f_2(Z') - f_1(Z \cap Z') - f_2(Z \cup Z') \geq \big(f_2(Z) - f_2(Z \cap Z')\big) - \big(f_2(Z \cup Z') - f_2(Z')\big) \geq 0,$$

the first step because $(f_1 - f_2)(Z) \geq (f_1 - f_2)(Z \cap Z')$ and the second by the submodularity of f_2, so that $\min(Z) + \min(Z') \geq f_1(Z \cap Z') + f_2(Z \cup Z') \geq \min(Z \cap Z') + \min(Z \cup Z')$; the case with f_1 and f_2 exchanged is the same with the roles of Z and Z' exchanged. So $r^\natural = \min(f_1, f_2)$ satisfies the rank axioms. Its value at $\mathcal{E} \sqcup G$ is $\min(r_{\mathcal{M}} + c, r_{\mathcal{N}} + c) = r_{\mathcal{M}}$, and $Y \sqcup P$ with $|Y| + |P| = r_{\mathcal{M}}$ is a basis exactly when $r_{\mathcal{M}}(Y) \geq |Y|$ and $r_{\mathcal{N}}(Y) \geq |Y| + |P| - c = r_{\mathcal{N}}$: Y independent in $\mathcal{M}$ and spanning $\mathcal{N}$, with $|Y| = r_{\mathcal{N}} + c - |P|$. For $Q \subseteq G$, $r^\natural(Q) = |Q|$, so the minor contracting Q and deleting $G \setminus Q$ has the rank function

$$Y \mapsto r^\natural(Y \sqcup Q) - |Q| = \min\big(r_{\mathcal{M}}(Y),\ r_{\mathcal{N}}(Y) + c - |Q|\big),$$

that of $\mathcal{L}_{c-|Q|}$, provided some basis contains Q and avoids $G \setminus Q$. Such bases exist for every Q: a basis Y_0 of $\mathcal{N}$ is independent in $\mathcal{M}$ by (i), it extends to a basis of $\mathcal{M}$ of $r_{\mathcal{N}} + c$ marks, and every set between the two is independent in $\mathcal{M}$ and spans $\mathcal{N}$. So every Q is a pattern, $d(G) = 0$, $r(G) = c$ and $c(G) = c$, and the child at Q is $\mathcal{L}_{c-|Q|}$ (Lemma 12.2). At $Q = \varnothing$ the rank function is $r_{\mathcal{M}}$, since $r_{\mathcal{M}}(Y) \leq r_{\mathcal{N}}(Y) + c$ by (i) at $X = Y$ and $\mathcal{E}$; at $Q = G$ it is $r_{\mathcal{N}}$, since $r_{\mathcal{N}} \leq r_{\mathcal{M}}$. The rank function depends on P through $|P|$ alone, so every permutation of G maps the bases onto themselves.

(iii) By (ii) $\mathcal{L}_j$ is the child at any Q of $c-j$ marks, a table, with the stated rank and bases, and $\mathcal{L}_0 = \mathcal{N}$, $\mathcal{L}_c = \mathcal{M}$. For $j \le j'$ take $Q' \subseteq Q$ with $|Q| = c-j$ and $|Q'| = c-j'$ and a chain of patterns from Q' to Q adding one mark at a time; each child is a quotient of the one before (Proposition 12.6), and by (i) $\mathcal{L}_j$ is a quotient of $\mathcal{L}_{j'}$. With the rank difference $b-a$ of $(\mathcal{L}_b, \mathcal{L}_a)$,

$$\min\big(r_{\mathcal{L}_b},\ r_{\mathcal{L}_a}+i\big) = \min\big(r_{\mathcal{M}},\ r_{\mathcal{N}}+b,\ r_{\mathcal{M}}+i,\ r_{\mathcal{N}}+a+i\big) = \min\big(r_{\mathcal{M}},\ r_{\mathcal{N}}+a+i\big),$$

since $i \ge 0$ and $a+i \le b$.

(iv) C is a pattern, so the minor is defined, and its bases are the sets $Y \sqcup (Q \setminus C)$ with $C \subseteq Q$, $Q \cap D = \varnothing$ and Y a basis of $\mathcal{L}_{c-|Q|}$. With $Q'' = Q \setminus C \subseteq G'' = G \setminus (C \cup D)$ and $c'' = c - |C| - |D| = |G''|$, $c - |Q| = |D| + (c'' - |Q''|)$, and by (iii) $\mathcal{L}_{|D|+i} = \mathcal{L}_i(\mathcal{L}_{c-|C|}, \mathcal{L}_{|D|})$ for $0 \le i \le c''$, the rank difference of that pair being c''. □

Lemma 30.3 (Complements of the lifts toward the dual). *As stated.*

Proof. Write $r(Y)$ and $r^*(Y)$ for the rank functions of $\mathcal{B}$ and $\mathcal{B}^*$, so that $r(\mathcal{E} \setminus X) = |\mathcal{E} \setminus X| + r^*(X) - r^*$ and $r^*(\mathcal{E} \setminus X) = |\mathcal{E} \setminus X| + r(X) - r$. By Proposition 30.2(iii) $\mathcal{L}_j$ is a table of rank $r+j$, with the rank function $r_{\mathcal{L}_j}(Y) = \min\big(r^*(Y),\ r(Y)+j\big)$ (30.1), and the rank function of its dual table is

$$\begin{aligned} |X| + r_{\mathcal{L}_j}(\mathcal{E} \setminus X) - r - j &= |X| + \min\big(n - |X| + r(X) - r,\ n - |X| + r^*(X) - r^* + j\big) - r - j \\ &= \min\big(r(X) + c - j,\ r^*(X)\big) = r_{\mathcal{L}_{c-j}}(X), \end{aligned}$$

using $n - 2r = c$ and $n - r^* - r = 0$. Two tables with one rank function have the same bases, the sets Y with $|Y| = r_{\mathcal{L}}(Y)$ equal to the rank; so the dual table of $\mathcal{L}_j$, whose bases are the complements of those of $\mathcal{L}_j$, has the bases of $\mathcal{L}_{c-j}$. □

Definition 30.4 (Fusion width; Foreman fusion; majors). As stated.

Proof. $c \ge 0$ for a quotient is Proposition 30.2(i). A quotient $\mathcal{N}$ of $\mathcal{M}$ of the same rank has $r_{\mathcal{N}} = r_{\mathcal{M}}$: (i) of that proposition gives $r_{\mathcal{M}}(Y) \ge r_{\mathcal{N}}(Y)$ at $X = \varnothing$, and $r_{\mathcal{N}}(X) \ge r_{\mathcal{M}}(X)$ at $Y = \mathcal{E}$; so the two have the same bases, the sets Y with $|Y| = r_{\mathcal{N}}(Y) = r_{\mathcal{N}}(\mathcal{E})$. At $c = 0$ a fusable table therefore has $\mathcal{B} = \mathcal{B}^*$ and $\theta^* = \theta$, its bases closed under complement with $\theta_{\mathcal{E}\setminus T} = \theta_T$; a list has $\theta^* = \theta$, so at $c = 0$ it is fusable exactly when $\mathcal{B} = \mathcal{B}^*$. The lifts are then the one table $\mathcal{L}_0 = \mathcal{L}_c$, with $\theta^{(0)} = \theta = \theta^* = \theta^{(c)}$. The condition on the weights pairs the bases of $\mathcal{L}_j$ with those of $\mathcal{L}_{c-j}$ by complement, which is a bijection by Lemma 30.3; at $j = 0$ it is the definition of θ^*. $L_0 = K_{\mathcal{B}^*} = \Psi$ (Proposition 7.2) and $L_c = K_{\mathcal{B}} = K$. Every permutation of G maps the bases of $\mathcal{B}^\sharp$ onto themselves (Proposition 30.2(ii)) and keeps their weights, which depend on X and $|Q|$ alone, so the partial fusion depends on G' only through $|G'|$, up to the names of its marks. □

Theorem 30.5 (Foreman fusion). *As stated.*

Proof. (i) Proposition 30.2(ii) with $(\mathcal{M}, \mathcal{N}) = (\mathcal{B}^*, \mathcal{B})$, $r_{\mathcal{M}} = r^*$, $r_{\mathcal{N}} = r$, gives the table, its rank, its rank function and the two minors; $n + c = 2n - 2r = 2r^*$. The bases $X \sqcup G$ carry $\theta^{(0)}_X = \theta_X$ and the bases $X \sqcup \varnothing$ carry $\theta^{(c)}_X = \theta^*_X$, so the contraction of G is $(\mathcal{B}, \theta)$ and the deletion is $(\mathcal{B}^*, \theta^*)$ (Definition 7.5).

(ii) By Lemma 30.3, X is a basis of $\mathcal{L}_j$ exactly when $\mathcal{E} \setminus X$ is a basis of $\mathcal{L}_{c-j}$, and with the weights $\theta^{(c-j)}_{\mathcal{E}\setminus X} = \theta^{(j)}_X$ the dual table of $(\mathcal{L}_j, \theta^{(j)})$ is $(\mathcal{L}_{c-j}, \theta^{(c-j)})$. A basis $X \sqcup Q$ of $\mathcal{B}^\sharp$, X a basis of $\mathcal{L}_{c-|Q|}$, has the complement $(\mathcal{E} \setminus X) \sqcup (G \setminus Q)$ with $\mathcal{E} \setminus X$ a basis of $\mathcal{L}_{|Q|} = \mathcal{L}_{c-|G\setminus Q|}$ and the

weight $\theta^{(|Q|)}_{\mathcal{E}\setminus X} = \theta^{(c-|Q|)}_X$: complementation maps the bases onto themselves with their weights. Summing $\theta^\sharp\alpha^{X\sqcup Q}$ over Q by its size gives $K^\sharp = \sum_l e_l(\alpha_G)K_{\mathcal{L}_{c-l}}$; $\Psi^\sharp = K^\sharp$ by Corollary 20.19; and $\Psi_{\mathcal{L}_l} = K_{\mathcal{L}^*_l} = K_{\mathcal{L}_{c-l}}$ by Proposition 7.2.

(iii) Let L be a major and $X\sqcup Q$ one of its bases; at $c=0$, $L=(\mathcal{B},\theta)=\mathcal{B}^\sharp$. In L the children of the bunch G at $\varnothing$ and at G are $\mathcal{B}^*$ and $\mathcal{B}$, so $\varnothing$ and G are patterns, $d(G)=0$ and G is independent; the contraction of the room onto G has the rank $d(G)=0$, so by Proposition 12.17(i) every subset of G is a pattern of G in L, and along chains of patterns from $\varnothing$ to Q and from Q to G the child at Q, of which X is a basis, is a quotient of $\mathcal{B}^*$ and has $\mathcal{B}$ as a quotient (Propositions 12.6 and 30.2(i)). So X is independent in $\mathcal{B}^*$ and spans $\mathcal{B}$ (Proposition 30.2(i)); it has $r^*-|Q| = r+c-|Q|$ marks, so it is a basis of $\mathcal{L}_{c-|Q|}$ (Proposition 30.2(iii)) and $X\sqcup Q$ is a basis of $\mathcal{B}^\sharp$.

(iv) The weights of $\mathcal{B}^\sharp$ depend on X and $|Q|$, so G is in level form in it (Definition 30.1). Let L be a major in which G is in level form. By Proposition 28.29(d) for L and its bunch G, the room sides of $r+j$ marks are the bases of the j-th lift of the table of the room sides of r marks, those of $L/G=\mathcal{B}$, toward the table of the room sides of $r+c$ marks, those of $L\setminus G=\mathcal{B}^*$: the bases of $\mathcal{L}_j$. A room side X of $r+j$ marks makes a basis with some pattern of $c-j$ marks, and in level form the children at all patterns of $c-j$ marks are one table, so $X\sqcup Q$ is a basis of L for every Q of $c-j$ marks: every basis of $\mathcal{B}^\sharp$ is a basis of L, and by (iii) the two have the same bases. The weights of L at $X\sqcup G$ and $X\sqcup\varnothing$ are those of its minors, θ and θ^*, and level form makes the others depend on X and $|Q|$ alone (Proposition 14.12); L is identically self-dual exactly when the weight of $X\sqcup Q$ equals that of $(\mathcal{E}\setminus X)\sqcup(G\setminus Q)$, that is when the middle weights are paired as in Definition 30.4(ii), and L is then the Foreman fusion whose middle weight $\theta^{(c-|Q|)}_X$ is the weight of $X\sqcup Q$. When L and $\mathcal{B}$ are lists all these weights are 1, and $L=\mathcal{B}^\sharp$. The transpositions generate the permutations of G, which gives the equivalent form (Proposition 14.12). A bijection β carrying $(\mathcal{B},\theta)$ carries $(\mathcal{B}^*,\theta^*)$, keeps r and r^*, and so keeps the rank function of every $\mathcal{L}_j$; with $\theta^{(j)}\circ\beta=\theta^{(j)}$, $\beta\sqcup\pi$ maps each basis $X\sqcup Q$ to the basis $\beta(X)\sqcup\pi(Q)$ of the same weight.

(v) At $c=1$, $\mathcal{L}_0=\mathcal{B}$ and $\mathcal{L}_1=\mathcal{B}^*$: the bases are $X+g$, $X\in\mathcal{B}$, with θ_X, and $X\in\mathcal{B}^*$ with θ^*_X, that is $\mathcal{E}\setminus T$ with θ_T; $K^\sharp = e_0L_0+e_1L_1 = \Psi+\alpha_gK$. A major L has $L/g=(\mathcal{B},\theta)$ and $L\setminus g=(\mathcal{B}^*,\theta^*)$, which fixes its bases through g and avoiding g with their weights: $L=\mathcal{B}^\sharp$. □

Theorem 30.6 (The tell). *As stated.*

Proof. Three facts about a table $\mathcal{B}$ of rank r. (α) A set A is closed in $\mathcal{B}^*$ exactly when $\mathcal{E}\setminus A$ is a union of circuits of $\mathcal{B}$: for $e\notin A$, $r^*(A+e)-r^*(A) = 1+r(\mathcal{E}\setminus A-e)-r(\mathcal{E}\setminus A)$, which is 1 exactly when e lies in the closure of $\mathcal{E}\setminus A-e$, that is in a circuit inside $\mathcal{E}\setminus A$. (β) The cocircuits are the complements of the closed sets of rank $r-1$: D meets every basis exactly when $\mathcal{E}\setminus D$ contains none, that is $r(\mathcal{E}\setminus D)\le r-1$, and D is minimal with this property exactly when $\mathcal{E}\setminus D$ is maximal with it, a closed set of rank $r-1$. (γ) The complement of a closed set A is a union of cocircuits: for $e\notin A$, a basis I of A has $I+e$ independent, $I+e$ extends to a basis T, and the closure H of $T-e$ has rank $r-1$, contains A, which lies in the closure of I, and avoids e, T being independent; so $\mathcal{E}\setminus H$ is a cocircuit through e inside $\mathcal{E}\setminus A$, by (β).

(a)⇒(b): the complement of a cocircuit is closed in $\mathcal{B}$ by (β), so in $\mathcal{B}^*$, and the cocircuit is a union of circuits by (α). (b)⇒(a): the complement of a closed set A of $\mathcal{B}$ is a union of cocircuits by (γ), each a union of circuits by (b), so A is closed in $\mathcal{B}^*$ by (α). (b)⇒(c): if e is not in the closure of A, (γ) applied to that closure gives a cocircuit D with $e\in D$ and $D\cap A=\varnothing$, so $D-e\subseteq A'$; by (b) a circuit C has $e\in C\subseteq D$, and e lies in the closure of $C-e\subseteq A'$. (c)⇒(b): for a cocircuit D and $e\in D$ split $\mathcal{E}\setminus\{e\}$ into $A=\mathcal{E}\setminus D$ and $A'=D-e$; A is closed by (β) and avoids e, so by (c) e lies in the closure of $D-e$, in a circuit inside D. By Proposition 30.2(i) (a) implies $c\ge 0$.

By Definition 30.4 the table is fusable exactly when (a) holds and, at $c = 0$, $\theta^* = \theta$, which a list always has. At $c = 0$, G is empty, a major is a table equal to $(\mathcal{B}, \theta)$ and to $(\mathcal{B}^*, \theta^*)$, and one exists exactly when $\mathcal{B} = \mathcal{B}^*$ and $\theta^* = \theta$, which is fusability, a quotient of the same rank having the same bases (proof of Definition 30.4). Let $c \geq 1$. A fusable table has a major, its Foreman fusion (Theorem 30.5(i), whose proof uses Proposition 30.2 alone). Conversely, in a major the children of the bunch G at $\varnothing$ and at G are $\mathcal{B}^*$ and $\mathcal{B}$, so $\varnothing$ and G are patterns, $d(G) = 0$ and G is independent; the contraction of the room onto G has rank $d(G) = 0$, and by Proposition 12.17(i) every subset of G is a pattern. Along a chain from $\varnothing$ to G adding one mark at a time each child is a quotient of the one before (Proposition 12.6), and $\mathcal{B}$ is a quotient of $\mathcal{B}^*$ by Proposition 30.2(i): the table is fusable. A table on $\mathcal{E} \sqcup G$ whose children at $\varnothing$ and at G have the bases of $\mathcal{B}^*$ and of $\mathcal{B}$ is a major once its bases $X \sqcup G$ carry θ_X and its bases $X \sqcup \varnothing$ carry θ^*_X, the two sets of bases being disjoint as $G \neq \varnothing$; this is the equivalent form of (d).

A coloop e makes $\{e\}$ a cocircuit, and a circuit inside $\{e\}$ would make e a loop; so (b) fails. The circuits of $\mathcal{B}^*$ are the cocircuits of $\mathcal{B}$ and its cocircuits the circuits of $\mathcal{B}$, which gives (b) for the dual. □

Corollary 30.7 (The fused tables are the identically self-dual tables). *As stated.*

Proof. (i) By Corollary 20.19 $\mathcal{H}$ has rank $|\mathcal{E}'|/2$ and no loop or coloop; C is independent in $\mathcal{H}$ and so in $\mathcal{H}^* = \mathcal{H}$. $\mathcal{H}/C$ has rank $|\mathcal{E}'|/2 - |C|$ on $|\mathcal{E}'| - |C|$ marks, hence the fusion width $|C|$. Its dual has the bases $(\mathcal{E}' \setminus C) \setminus (T \setminus C) = \mathcal{E}' \setminus T$, $T \supseteq C$, with the weights $\theta_T = \theta_{\mathcal{E}' \setminus T}$: the bases of $\mathcal{H}$ avoiding C with their weights, so $(\mathcal{H}/C)^* = \mathcal{H} \setminus C$ and $\mathcal{H}$ is a major of $\mathcal{H}/C$. By Theorem 30.6 $\mathcal{H}/C$ is fusable; C is in level form in $\mathcal{H}$ (Proposition 14.12), and $\mathcal{H}$ is identically self-dual, so by Theorem 30.5(iv) it is the Foreman fusion of $\mathcal{H}/C$ with the middle weights $\theta^{(j)}_X = \theta_{X \sqcup Q}$, $|Q| = c - j$. A one-mark set is independent, $\mathcal{H}$ having no loop, and it has no transposition. With Theorem 30.5(ii) the fused tables are exactly the identically self-dual ones.

(ii) $c(S) = |S| - d(S) - d^*(S)$ does not change under duality, which exchanges d and d^*, so $\mathcal{B}^*$ is connected and its circuits link all of $\mathcal{E}$ (Proposition 28.3(i)). The circuits of $\mathcal{B}^* = \mathcal{B}^\sharp \setminus G$ are circuits of $\mathcal{B}^\sharp$, so $\mathcal{E}$ lies in one molecule of $\mathcal{B}^\sharp$. For $g \in G$ take a basis $X \sqcup Q$ with $g \notin Q$; the circuit through g inside $X \sqcup Q + g$ does not lie in the independent set G, so it meets $\mathcal{E}$, and g lies in the molecule of $\mathcal{E}$. So $\mathcal{B}^\sharp$ is one molecule, connected by Proposition 28.3(i). □

Proposition 30.8 (Partial fusions and inner lifts). *As stated.*

Proof. (i) is Proposition 30.2(iv) for $(\mathcal{B}^*, \mathcal{B})$, the minor carrying the weights of $\mathcal{B}^\sharp$ (Definition 7.5). (ii) With $C = G \setminus G'$ and $D = \varnothing$, (i) gives the level cell of $(\mathcal{L}_i, \mathcal{B})$, of rank $r + i$ on $n + i$ marks, so of the fusion width $c - i$. Being identically self-dual, $\mathcal{B}^\sharp$ has $(\mathcal{B}^\sharp/(G \setminus G'))^* = \mathcal{B}^\sharp \setminus (G \setminus G')$ with the weights, as in the proof of Corollary 30.7(i); $G \setminus G'$ is independent and in level form in $\mathcal{B}^\sharp$ (Proposition 30.2(ii), Definition 30.1); so Corollary 30.7(i) makes $\mathcal{B}^\sharp_i$ fusable with the Foreman fusion $\mathcal{B}^\sharp$, its middle weights read off $\theta^\sharp$. (iii) $\mathcal{L}_j$ has the rank $r+j$ and the corank $n-r-j = r+c-j$, so the fusion width $c - 2j$. For $2j \leq c$, $\mathcal{L}_j$ is a quotient of $\mathcal{L}_{c-j} = \mathcal{L}^*_j$ (Proposition 30.2(iii) and Theorem 30.5(ii)), and at $2j = c$, where $\mathcal{L}^*_j = \mathcal{L}_j$, its weights are those of its dual, $\theta^{(j)}_{\mathcal{E} \setminus X} = \theta^{(j)}_X$; so it is fusable, and its lifts toward its dual are the $\mathcal{L}_{j+i}$, $0 \leq i \leq c - 2j$ (Proposition 30.2(iii)). Its level cell is $\mathcal{B}^\sharp/C \setminus D$ with $|C| = |D| = j$ by (i), whose weights are paired by complement as those of $\mathcal{B}^\sharp$ are, so it is the Foreman fusion of $(\mathcal{L}_j, \theta^{(j)})$ with the middle weights read off $\theta^\sharp$. At $j = c/2$ the lift is identically self-dual; at $j = (c-1)/2$ the fusion width is one. □

Proposition 30.10 (The seam of the fusion bunch). *As stated.*

Proof. (i) $\mathrm{pat}(G) = 2^G$, $d(G) = 0$, $c(G) = c$ and level form are Proposition 30.2(ii) and Definition 30.1. A pattern Q of l marks has the child $(\mathcal{L}_{c-l}, \theta^{(c-l)})$, the same for all of them, so they form one station with the multipliers 1 (Definition 28.1); its station letters are $\sum_{|Q|=l} \alpha_G^Q = e_l(\alpha_G)$ and $\sum_{|Q|=l} \alpha_G^{G\setminus Q} = e_{c-l}(\alpha_G)$. A room side X of excess l is a basis of $\mathcal{L}_{c-l}$, its size fixing l, and its room child has the bases of $\binom{G}{l}$, each with the weight $\theta_X^{(c-l)}$: all the room children of the excess l are positive multiples of $\binom{G}{l}$, one station D_l, with the multipliers $w'_X = \theta_X^{(c-l)}/\mu_l$ and the room child of the station $\mu_l\binom{G}{l}$, of the letters $\mu_l e_l$ and $\mu_l e_{c-l}$. The room-station letters are $\sum_X w'_X \alpha^X = L_l/\mu_l$ and $\sum_X w'_X \alpha^{\mathcal{E}\setminus X} = \Psi_{\mathcal{L}_{c-l}}/\mu_l = L_{c-l}/\mu_l$ (Theorem 30.5(ii)), and the pair constant is $\theta_X^{(c-l)}/(1 \cdot w'_X) = \mu_l$. One station on each side at each excess is one rectangle, and the room-station factorization of Proposition 28.2(iii) is the stated one. The weight of $X \sqcup Q$ depends on X alone, $|X|$ fixing $|Q|$, so the weights factor across G and $\mathcal{E}$ and Theorem 28.28 applies: with one rectangle at every excess the table is its level envelope.

(ii) By Definition 12.18, with $K_{(Q)} = K_{\mathcal{L}_{c-|Q|}}$ and $\Psi_{(Q)} = \Psi_{\mathcal{L}_{c-|Q|}} = K_{\mathcal{L}_{|Q|}}$,

$$\iota_G = \sum_{l=0}^{c} \binom{c}{l} (-1)^{c-l} \log K_{\mathcal{L}_{c-l}}, \qquad \iota_G^* = \sum_{l=0}^{c} \binom{c}{l} (-1)^{l} \log K_{\mathcal{L}_l},$$

both equal to $\sum_j (-1)^j \binom{c}{j} \log K_{\mathcal{L}_j}$; at $c = 2$ this is $\log K_{\mathcal{L}_0} - 2\log K_{\mathcal{L}_1} + \log K_{\mathcal{L}_2} = -\log z_1$.

(iii) At the table's gauge the pattern probability of Q is $K_{(Q)}(\mathbf{1})/K^\sharp(\mathbf{1}) = L_{|Q|}(\mathbf{1})/K^\sharp(\mathbf{1})$ (Definition 12.25); the $\binom{c}{l}$ patterns of l marks give Π_l. $L_l(\mathbf{1})$ is the total weight of $(\mathcal{L}_{c-l}, \theta^{(c-l)})$, which equals that of its dual $(\mathcal{L}_l, \theta^{(l)})$, $L_{c-l}(\mathbf{1})$; so $\Pi_l = \Pi_{c-l}$. The peel (Definition 14.1) gives the child at Q the exponents $\pi_Q(\mathbf{1})(s,t)$, and merging the equal children of each excess gives $(\mathcal{L}_{c-l}; \Pi_l s, \Pi_l t)$, that is $(\mathcal{L}_j; \Pi_j s, \Pi_j t)$. Its word is $\prod_j K_{\mathcal{L}_j}^{-\Pi_j s} \Psi_{\mathcal{L}_j}^{-\Pi_j t} = \prod_j K_{\mathcal{L}_j}^{-\Pi_j s} \prod_j K_{\mathcal{L}_{c-j}}^{-\Pi_j t} = \prod_j K_{\mathcal{L}_j}^{-\Pi_j (s+t)}$, reindexing the second product by $j \mapsto c - j$. □

Definition 30.11 (The universal piece; the lift partner). As stated.

Proof. The seam letters e_l and e_{c-l} of the station D_l are nonzero, with nonnegative coefficients, homogeneous of the degrees $l = d + l$ and $c - l = d^* + c - l$ with $d = d^* = 0$, and positive letters where the degree is positive; the room letters $L_l = K_{\mathcal{L}_{c-l}}$ and L_{c-l} have the degrees $r + c - l = e + c - l$ and $r + l = e^* + l$ with $e = e^* = r$, as Definition 28.4 asks of a partner read with the reversed excesses. □

Theorem 30.12 (The glue of a fused table). *As stated.*

Proof. The family $((\mathcal{B}^\sharp, \theta^\sharp); 2\sigma, 0)$ has the word $K^{\sharp\,-2\sigma} = K^{\sharp\,-s} \Psi^{\sharp\,-t}$ (Theorem 30.5(ii)), and it is the glue of the universal piece and the lift partner with the one active letter K (Definition 28.4, Proposition 30.10(i)).

(i) In Definition 28.5 with the one active letter at the exponent 2σ: $\kappa_G = m_G$, $\kappa_G + \kappa_G^{\mathrm{top}} = 2\sigma c$, $V^{(0)} = e_0 = 1$ and $V^{(c)} = e_c$, so $\gamma_G^\rho = e_c^{1/c}$, the scale form is $\phi_G^\rho(du) = u^{\mathbf{m}|_G - \mathbf{1}} e_c(u)^{-m_G/c}\, d\omega_G(u)$, and the seam vector at D_l is $e_l/(\gamma_G^\rho)^l$. The form $\nu_G = \alpha^{\mathbf{m}|_G - \mathbf{1}} e_c(\alpha)^{-m_G/c}\, d\alpha$ on $(0,\infty)^G$ and the seam vector are homogeneous of degree zero. For a Borel $\psi \geq 0$ on the seam torus and $\mathbf{1}_{[1,e]}$ the indicator of $[1,e]$, with $\int_0^\infty \mathbf{1}_{[1,e]}(\rho)\, d\rho/\rho = 1$, the integral of $\psi(\boldsymbol{\varrho}_G^\rho(\alpha))\, \mathbf{1}_{[1,e]}(h(\alpha))\, \nu_G$ over the orthant is, for every positive h of degree one, the integral of $\psi(\boldsymbol{\varrho}_G^\rho)$ against the law: in the coordinates $\alpha = \rho u$ of scale and shape (Lemma 2.7) the form is $\mathbf{1}_{[1,e]}(\rho)\, d\rho/\rho$ times ϕ_G^ρ, the integrand not depending on ρ, and a change of the section h is a change of ρ along each ray, which leaves $\int \mathbf{1}_{[1,e]}(\rho)\, d\rho/\rho$ unchanged (the computation of Lemma 16.2, in $[0,\infty]$ by Tonelli). Take

$h = e_c^{1/c}$ and write $\alpha = \rho\, e^w$ with $\rho > 0$, $w \in H_G$. In the coordinates $y = \log\alpha = \lambda\mathbf{1} + w$, $\lambda = \log\rho$, the map $(\lambda, w_{g_1}, \dots, w_{g_{c-1}}) \mapsto y$, $w_{g_c} = -\sum_{i<c} w_{g_i}$, is linear with determinant $\pm c$: adding all rows to the last turns it into $(c, 0, \dots, 0)$. So $d\alpha = \alpha^{\mathbf{1}} c\, d\lambda\, d\lambda_G(w)$, and since $e_c(\rho e^w) = \rho^c$,

$$\nu_G = e^{m_G\lambda + \langle \mathbf{m}|_G, w\rangle}\, e^{-m_G\lambda}\, c\, d\lambda\, d\lambda_G(w) = c\, e^{\langle \mathbf{m}|_G, w\rangle}\, \frac{d\rho}{\rho}\, d\lambda_G(w),$$

while $\boldsymbol{\varrho}_G^{\rho}(\rho e^w) = \mathbf{e}(e^w)$. So the integral of ψ against the law is $c\int_{H_G} \psi(\mathbf{e}(e^w))\, e^{\langle \mathbf{m}|_G, w\rangle}\, d\lambda_G(w)$ for every ψ, which is the statement.

(ii) By Lemma 16.2, in $[0,\infty]$ by Tonelli, $P_{\mathcal{B}^\sharp}(\mathbf{m}; s, t)$ is the integral over the orthant of $\alpha^{\mathbf{m}-\mathbf{1}} K^{\sharp\,-2\sigma} \mathbf{1}_{[1,e]}(h(\alpha))\, d\alpha$ with $h = e_c(\alpha_G)^{1/c}$. In the coordinates $(\alpha_{\mathcal{E}}, \rho, w)$, $\alpha_G = \rho e^w$, as in (i), $\alpha_G^{\mathbf{m}|_G - \mathbf{1}} d\alpha_G = c\, e^{\langle \mathbf{m}|_G, w\rangle} \rho^{m_G - 1} d\rho\, d\lambda_G(w)$ and $K^\sharp = \sum_l \rho^l e_l(e^w) L_l(\alpha_{\mathcal{E}})$ (Theorem 30.5(ii)). By Tonelli the integral is $c\int_{H_G} e^{\langle \mathbf{m}|_G, w\rangle} I(w)\, d\lambda_G(w)$ with

$$I(w) = \int_{(0,\infty)^{\mathcal{E}} \times (0,\infty)} \alpha_{\mathcal{E}}^{\mathbf{m}|_{\mathcal{E}} - \mathbf{1}} \rho^{m_G - 1} \Big(\sum_l e_l(e^w) \rho^l L_l(\alpha_{\mathcal{E}}) \Big)^{-2\sigma} \mathbf{1}_{[1,e]}(\rho)\, d\alpha_{\mathcal{E}}\, d\rho.$$

The letter $\sum_l x_l \alpha_g^l L_l$ is homogeneous of degree $r + c = r^*$ on $\mathcal{E} \sqcup \{g\}$, so the form of $W[\mathbf{x}]$ at the masses $(\mathbf{m}|_{\mathcal{E}}, m_G)$ has degree $m_{\mathcal{E}} + m_G - 2\sigma r^* = 0$ on the balance wall, and $I(w)$ is its integral against $\mathbf{1}_{[1,e]}$ of the section function α_g: by Lemma 16.2 it is $P_{W[\mathbf{e}(e^w)]}(\mathbf{m}|_{\mathcal{E}}, m_G)$.

(iii) $\sum_l x_l L_l y^l$ is a polynomial of degree c in y with positive coefficients, $x_c L_c \neq 0$, so its roots $-\xi_i$ avoid $[0,\infty)$; read as in Definition 12.10 on the bunch $\{g\}$, whose floor is 0, its Skeleton polynomial at $\alpha_g = 1$ is $\prod_i (x + \xi_i)/(1 + \xi_i)$. Non-real roots come in conjugate pairs, and for $\rho > 0$ the product of the principal powers $(\rho + \xi_i)^{-2\sigma}$ is the positive power of the product. Proposition 15.1 with $J = \{1, \dots, c\}$, the letter exponents $w_i = 2\sigma$, $|\mathbf{w}| = 2\sigma c$ and $\kappa = m_G$ gives the formula for $0 < m_G < 2\sigma c$, coincident values merging.

(iv) This is Theorem 28.10(iii) for the universal piece and the lift partner with the one active letter: one share $a_l = a_{D_l}$ per station, the letter total $\sum_l a_l = 2\sigma$ and the scale pin $\sum_l i(D_l) a_l = \kappa_G = m_G$, the share kernel $\Gamma_{\substack{c+1 \\ 1}} \begin{bmatrix} \mathbf{a} \\ 2\sigma \end{bmatrix}$, and the two seam functions, which on the pins are the periods of the seam word $\prod_l e_l^{-a_l}$ at $\mathbf{m}|_G$ and of the room word $\prod_l L_l^{-a_l}$ at $\mathbf{m}|_{\mathcal{E}}$ (Lemma 28.7), $e_0 = 1$ dropping out. Two pins on $c+1$ shares leave a fibre of dimension $c - 1$.

Let the masses be real and every proper wall of $\mathcal{B}^\sharp$ positive; we show that both periods converge at the native split at the stations. The walls of $((\mathcal{B}^\sharp, \theta^\sharp); 2\sigma, 0)$ are $\kappa_U = m_U - 2\sigma d^\sharp(U)$, with $d^\sharp(U) = r^* - r^\sharp(\mathcal{E}^\sharp \setminus U)$ on $\mathcal{E}^\sharp = \mathcal{E} \sqcup G$; at one mark, no mark being a coloop (Corollary 20.19), $d^\sharp$ is 0, so the masses are positive. A set U of the width zero in $\mathcal{B}^\sharp$ has $r^\sharp(U) + r^\sharp(\mathcal{E}^\sharp \setminus U) = r^*$, so $d^\sharp(U) = r^\sharp(U)$ and $d^\sharp(\mathcal{E}^\sharp \setminus U) = r^\sharp(\mathcal{E}^\sharp \setminus U)$, and $\kappa_U + \kappa_{\mathcal{E}^\sharp \setminus U} = m_{\mathcal{E}^\sharp} - 2\sigma r^* = 0$ on the balance wall; so no nonempty proper U has the width zero, $\mathcal{B}^\sharp$ is connected (Proposition 28.3(i)), and it has a native gauge (Theorem 8.19(iii)). By Lemma 28.9, $c(G) = c \geq 1$, the native split at the stations is a point of the pins with positive shares a_l at which $\mathbf{m}|_G$ and $\mathbf{m}|_{\mathcal{E}}$ lie in the relative interiors of the Newton sums of the seam word and of the room word, and the two words converge there once these Newton sums have the full dimensions $c - 1$ and $n - 1$; the seam letters $\mu_l e_l$ and the room-station letters L_l/μ_l of the bunch G (Proposition 30.10(i)) differ from e_l and L_l by constant factors, which change neither the Newton sums nor the convergence. The Newton sum $\sum_{l \geq 1} a_l \mathcal{N}_{e_l}$ of the seam word contains a translate of $a_1 \operatorname{conv}\{\mathbf{1}_{\{g\}} : g \in G\}$, of the dimension $c - 1$. The Newton sum $\sum_l a_l \mathcal{N}_{L_l}$ of the room word, $\mathcal{N}_{L_l}$ the base polytope of $\mathcal{L}_{c-l}$, has as its directions the sums of the directions of its terms, so a vector $w \in \mathbb{R}^{\mathcal{E}}$ orthogonal to them has $\langle w, \mathbf{1}_X \rangle$ constant over the bases X of every lift, and w is constant on every molecule of the family

of the lifts (Lemma 7.8). That family is connected. Otherwise a proper nonempty $S \subset \mathcal{E}$ is a union of its molecules, hence of molecules of every lift (Proposition 7.9), and has the width zero in $\mathcal{L}_0 = \mathcal{B}$ and in $\mathcal{L}_1$, whose rank function is $r(Y) + \min(-\varepsilon(Y), 1)$, $\varepsilon(Y) = r(Y) - r^*(Y) \le 0$ the slant of Y in $\mathcal{B}$ (Definition 7.12, Proposition 30.2(i)). The two widths give $r(S) + r(\mathcal{E} \setminus S) = r$ and $\min(-\varepsilon(S), 1) + \min(-\varepsilon(\mathcal{E} \setminus S), 1) = 1$, so $\varepsilon(S) = 0$ or $\varepsilon(\mathcal{E} \setminus S) = 0$, say $\varepsilon(S) = 0$, exchanging S and $\mathcal{E} \setminus S$ if needed. Then by Theorem 30.5(i) $r^\sharp(S) = \min(r^*(S), r(S) + c) = r(S)$ and $r^\sharp((\mathcal{E} \setminus S) \sqcup G) = \min(r^*(\mathcal{E} \setminus S) + c,\ r(\mathcal{E} \setminus S) + c) = r(\mathcal{E} \setminus S) + c$, whose sum is $r + c = r^*$: S has the width zero in $\mathcal{B}^\sharp$, which is excluded. So w is constant, the Newton sum of the room word has the dimension $n - 1$, and both words converge at the native split (Lemma 28.9, Theorem 25.2).

(v) $e_c(\alpha_G) = \alpha_G^{\mathbf{1}}$, so $\alpha_G^{\mathbf{m}|_G - \mathbf{1}} \prod_{l=1}^{c} e_l^{-a_l} = \alpha_G^{(\mathbf{m}|_G - a_c\mathbf{1}) - \mathbf{1}} \prod_{l=1}^{c-1} e_l^{-a_l}$: the two forms are one, and so are their periods; e_l is the letter of $\binom{G}{l}$. At $c = 1$ the pins give $a_1 = m_g$, and the form $\alpha_g^{m_g - 1} \alpha_g^{-a_1} d\alpha_g$ on one mark has the period 1. At $c = 2$, $u_1 + u_2 = 1$ on Δ_G, so the period of $e_1^{-a_1}$ at $(m_1 - a_2, m_2 - a_2)$ is $\int_{\Delta_G} u^{(\mathbf{m}|_G - a_2\mathbf{1}) - \mathbf{1}} d\omega_G = \Gamma_{\substack{2\\1}}\!\left[\begin{matrix} m_1 - a_2,\ m_2 - a_2 \\ a_1 \end{matrix}\right]$ (Theorem 3.9), $m_1 + m_2 - 2a_2 = a_1$ on the pins. □

Corollary 30.13 (Width one). *As stated.*

Proof. $\mathcal{B}^\sharp$ is identically self-dual (Theorem 30.5(ii)), and Corollary 20.19 at the mark g, which allows the exponents $(2\sigma, 0)$, gives $P_{\mathcal{B}^\sharp} = \Gamma_{\substack{2\\1}}\!\left[\begin{matrix} m_g,\ 2\sigma - m_g \\ 2\sigma \end{matrix}\right] P_{\mathcal{B}^\sharp \setminus g}(\mathbf{m}|_{\mathcal{E}}; 2\sigma - m_g, m_g)$. $\mathcal{B}^\sharp \setminus g = (\mathcal{B}^*, \theta^*)$, whose letters are Ψ and K (Proposition 7.2), so its period at $(2\sigma - m_g, m_g)$ is $P_{\mathcal{B}}(\mathbf{m}|_{\mathcal{E}}; m_g, 2\sigma - m_g)$. At $c = 1$, $H_G = \{0\}$ and the seam vector of the universal piece is $(1, 1)$; that of the lift partner, $\big(L_0/(L_1\gamma_{\mathcal{E}}),\ L_1/L_1\big)$ with $\gamma_{\mathcal{E}} = L_0/L_1$ (Definition 28.5, read with the reversed excesses), is $(1, 1)$; and the two pins fix $a_0 = 2\sigma - m_g$ and $a_1 = m_g$. □

Corollary 30.14 (Width two). *As stated.*

Proof. (i) Theorem 30.12(iv) and (v) at $c = 2$: the pins give $a_1 = m_1 + m_2 - 2a_2$ and $a_0 = 2\sigma - m_1 - m_2 + a_2$, solved for (a_0, a_1) by a matrix of determinant one, and the kernel times the universal factor is $\frac{\Gamma(a_0)\Gamma(a_1)\Gamma(a_2)}{\Gamma(2\sigma)} \cdot \frac{\Gamma(m_1 - a_2)\Gamma(m_2 - a_2)}{\Gamma(a_1)}$. (ii) Theorem 30.12(i) and (ii) at $c = 2$: $H_G = \{(w, -w)\}$ with $d\lambda_G = dw$, $v = e^w$, $\mathbf{e}(e^w) = (1, v + v^{-1}, 1)$ and $2e^{(m_1 - m_2)w} dw = 2v^{m_1 - m_2 - 1} dv$. (iii) $K^\sharp = A + \alpha_{g_2} B$ with $A = L_0 + \alpha_{g_1} L_1$ and $B = L_1 + \alpha_{g_1} L_2$, and $\int_0^\infty \rho^{\nu - 1}(A + B\rho)^{-2\sigma} d\rho = \Gamma_{\substack{2\\1}}\!\left[\begin{matrix} \nu,\ 2\sigma - \nu \\ 2\sigma \end{matrix}\right] A^{\nu - 2\sigma} B^{-\nu}$ for $0 < \nu < 2\sigma$ (Proposition 15.1) at $\nu = m_2$. With $\alpha_{g_1} = (L_0/L_1)x$, $A = L_0(1 + x)$ and $B = L_1(1 + z_1^{-1}x)$, which gives the display by Tonelli; the x-integral is $z_1^{m_2} \int_0^\infty x^{m_1 - 1}(x + 1)^{-(2\sigma - m_2)}(x + z_1)^{-m_2} dx$, the scale integral of Proposition 15.1 with the coefficients $1, z_1$, the letter exponents $2\sigma - m_2, m_2$ and $\kappa = m_1$, finite exactly for $0 < m_1 < 2\sigma$. At $m_1 = m_2 = 1$, $2\sigma = 2$, $\int_0^\infty \frac{dx}{(1+x)(1+x/z_1)} = \frac{z_1 \log z_1}{z_1 - 1}$ for $z_1 \ne 1$ and 1 for $z_1 = 1$, and $L_1^{-2} z_1 \log z_1/(z_1 - 1) = \log z_1/(L_1^2 - L_0 L_2)$. At integer data and $z_1 \ne 1$ the integrand is a rational function of x with poles at -1 and $-z_1$ only and of order at most x^{-2} at infinity, $m_1 < 2\sigma$; its partial fractions give an antiderivative $R(x) + A' \log(1 + x) + B' \log(1 + x/z_1)$ with R rational and $A' + B' = 0$, all coefficients rational in z_1, whose increment over $(0, \infty)$ is $R(\infty) - R(0) + A' \log z_1$ (receipt `t10b_weight_exact.py` for $m_1 = m_2 = k$, $2\sigma = 2k$, $k \le 4$). □

Lemma 30.15 (Products of lifts). *As stated.*

Proof. Let A be a basis of $\mathcal{L}_i$. Since $\mathcal{L}_i$ is a quotient of $\mathcal{L}_j$ (Proposition 30.2(iii)), A is independent in $\mathcal{L}_j$ (Proposition 30.2(i)) and lies in a basis C of $\mathcal{L}_j$. The monomial $\alpha^{\mathbf{1}_A+\mathbf{1}_C} = \alpha^{2\mathbf{1}_A+\mathbf{1}_{C\setminus A}}$ occurs in $K_{\mathcal{L}_i}K_{\mathcal{L}_j}$ with a positive coefficient, every coefficient being nonnegative, and exactly $|A| = r_{\mathcal{N}}+i$ of its exponents equal 2. A monomial $\alpha^{\mathbf{1}_{A'}+\mathbf{1}_{C'}}$ of $K_{\mathcal{L}_{i'}}K_{\mathcal{L}_{j'}}$ has the exponent 2 exactly on $A'\cap C'$, at most $|A'| = r_{\mathcal{N}}+i' < r_{\mathcal{N}}+i$ marks. Both products are nonzero with nonnegative coefficients, so a positive constant multiple of one has the support of the one, and they are not proportional. The ratio is the case $(i',i,j,j') = (j-1,j,j,j+1)$, $0<j<c$; a constant ratio would make $K^2_{\mathcal{L}_j} - \lambda K_{\mathcal{L}_{j-1}}K_{\mathcal{L}_{j+1}}$ vanish on the orthant, hence identically. □

Theorem 30.16 (The price of width). *As stated.*

Proof. (i) By Theorem 30.12(i) the universal law is the image of a measure with a positive continuous density on H_G, of dimension $c-1$, under the continuous map $w \mapsto \mathbf{e}(e^w)$. At $c=1$ it is the unit point mass at $(1,1)$. At $c\ge 2$, $e_1(e^w) = \sum_g e^{w_g}$ is c at $w=0$ and larger at every other point of H_G by the inequality of the arithmetic and geometric means, $\prod_g e^{w_g} = 1$; a law carried by one point would make it constant almost everywhere, hence everywhere by continuity. The law of the lift partner is the image of its scale form, which has a positive continuous density on the open simplex $\Delta_{\mathcal{E}}$, under its continuous seam vector; it is carried by one point exactly when the seam vector is constant. Read with the reversed excesses, $V^{(0)} = L_c$, $V^{(c)} = L_0$, the scale is $\gamma_{\mathcal{E}} = (L_0/L_c)^{1/c}$ and the seam vector at D_l is $L_l/(L_c\gamma_{\mathcal{E}}^{c-l}) = L_l L_0^{-(c-l)/c} L_c^{-l/c}$ (Definition 28.5). Put $f_l = \log L_l - \log L_0 - \frac{l}{c}(\log L_c - \log L_0)$, so that $f_0 = f_c = 0$ and the second differences of $(f_l)_l$ are those of $(\log L_l)_l$, which are $-\log z_{c-l}$, since $L_l = K_{\mathcal{L}_{c-l}}$. The seam vector is constant exactly when every f_l is constant; then every lift ratio is constant, and conversely constant second differences with $f_0 = f_c = 0$ determine f_l as constants. At $c=1$ there is no lift ratio and the seam vector is $(1,1)$; at $c\ge 2$ Lemma 30.15 excludes constant lift ratios.

(ii) For $a\in\mathbb{C}^c$ and a set S of l indices, $\pi(S)$ runs over the sets of l indices as π runs over S_c, each reached $l!\,(c-l)!$ times, so

$$\sum_{\pi\in S_c}\prod_{i=1}^{c}\bigl(1+a_i\eta_{\pi(i)}\bigr) = \sum_S a^S \sum_\pi \prod_{i\in S}\eta_{\pi(i)} = \sum_{l=0}^{c} l!\,(c-l)!\,e_l(a)\,e_l(\boldsymbol{\eta}),$$

and the left side is $\operatorname{per}(\mathbf{1}\mathbf{1}^{\mathsf{T}}+a\boldsymbol{\eta}^{\mathsf{T}})$ by the definition of the permanent. With $L_l = L_0 e_l(\boldsymbol{\eta})/\binom{c}{l}$, read off $\sum_l \binom{c}{l}L_l x^l = L_0\prod_i(1+\eta_i x)$, division by $c!$ gives $\sum_l e_l(\alpha_G)L_l = K^\sharp$. The Skeleton polynomial of G at $(\mathbf{1}_G,\alpha_{\mathcal{E}})$ is $K^\sharp(x\mathbf{1}_G,\alpha_{\mathcal{E}})/K^\sharp(\mathbf{1}_G,\alpha_{\mathcal{E}}) = \sum_l\binom{c}{l}L_l x^l/K^\sharp$, $d(G)=0$, and with $L_0>0$ its roots $-\xi_i$ give $\sum_l\binom{c}{l}L_l x^l = L_0\prod_i(1+x/\xi_i)$: $\eta_i = 1/\xi_i$. At a gauge all η_i equal η exactly when $\sum_l\binom{c}{l}L_l x^l = L_0(1+\eta x)^c$, that is $L_l = L_0\eta^l$ for every l, which holds exactly when $L_l^2 = L_{l-1}L_{l+1}$ for $0<l<c$ (then $L_l = L_0(L_1/L_0)^l$ by induction), that is every lift ratio is 1. Coincidence on an open set would make $K^2_{\mathcal{L}_j} - K_{\mathcal{L}_{j-1}}K_{\mathcal{L}_{j+1}}$ vanish there and so identically, against Lemma 30.15; and $K^\sharp = L_0\prod_g(1+\alpha_g\eta) = L_0\sum_l e_l(\alpha_G)\eta^l$ would give $L_l = L_0\eta^l$ everywhere.

(iii) By Proposition 30.8(ii) the partial fusion $\mathcal{A}$ at G' is the level cell of $(\mathcal{L}_i,\mathcal{B})$ on $\mathcal{E}\sqcup G'$, in which g lies in some bases and avoids others, so it is a cell with the hinge g; by Proposition 30.2(iv) its hinge minors are $\mathcal{A}/g$, the level cell of $(\mathcal{L}_{i-1},\mathcal{B})$, and $\mathcal{A}\setminus g$, the level cell of $(\mathcal{L}_i,\mathcal{L}_1)$, both on $\mathcal{E}\sqcup(G'-g)$. At $i=c$, $\mathcal{A} = \mathcal{B}^\sharp$ is identically self-dual, $\mathcal{A}/g$ is the dual of $\mathcal{A}\setminus g$ with the same weights (as in the proof of Corollary 30.7(i)), so $K_{\mathcal{A}/g} = \Psi_{\mathcal{A}\setminus g}$ and $\Psi_{\mathcal{A}/g} = K_{\mathcal{A}\setminus g}$ (Proposition 7.2) and the ratio is 1; and Corollary 20.19 at g, with $P_{\mathcal{A}\setminus g}$ at $(2\sigma-m_g,m_g)$ equal to $P_{\mathcal{A}/g}$ at $(m_g,2\sigma-m_g)$, gives the display. Let $i<c$. The letters of a level cell of $(\mathcal{M}',\mathcal{N}')$ on $\mathcal{E}\sqcup G''$ are $K = \sum_Q \alpha^Q K_{\mathcal{L}'_{c''-|Q|}}$ and $\Psi = \sum_Q \alpha^{G''\setminus Q}\Psi_{\mathcal{L}'_{c''-|Q|}}$, which at $\alpha_{G''}=0$ are $K_{\mathcal{M}'}$ and $\Psi_{\mathcal{N}'}$. So at $\alpha_{G'-g}=0$ the even

letters of the hinge minors are

$$\mathbf{E}_{\mathcal{A}/g} = K_{\mathcal{L}_{i-1}}\Psi_{\mathcal{B}} = K_{\mathcal{L}_{i-1}}K_{\mathcal{L}_c}, \qquad \mathbf{E}_{\mathcal{A}\setminus g} = K_{\mathcal{L}_i}\Psi_{\mathcal{L}_1} = K_{\mathcal{L}_i}K_{\mathcal{L}_{c-1}}.$$

A constant ratio $\varrho_{\mathcal{A}} = \mathbf{E}_{\mathcal{A}/g}/\mathbf{E}_{\mathcal{A}\setminus g}$ on the orthant would make $\mathbf{E}_{\mathcal{A}/g} - \lambda\mathbf{E}_{\mathcal{A}\setminus g}$ vanish identically, also at $\alpha_{G'-g} = 0$, against Lemma 30.15 with $(i', i, j, j') = (i-1, i, c-1, c)$. The law of the cell is the image of its base form, with a positive continuous density on the open simplex, under the continuous ratio, and it is carried by one point only if the ratio is constant (Corollary 23.12(i)). □

Proposition 30.17 (The free extensions by one mark). *As stated.*

Proof. Write $K_\backslash, \Psi_\backslash$ and $K_/, \Psi_/$ for the letters of $\mathcal{A}\setminus g$ and $\mathcal{A}/g$, of the degrees $r_{\mathcal{A}}$, $|\mathcal{E}| - r_{\mathcal{A}}$, $r_{\mathcal{A}} - 1$ and $|\mathcal{E}| - r_{\mathcal{A}} + 1$; $\mathcal{A}$ being plain, each hinge minor carries one system of weights in its two letters. If $\mathcal{A}/g$ is the dual of $\mathcal{A}\setminus g$ with its weights multiplied by μ, then $K_/ = \mu\Psi_\backslash$ and $\Psi_/ = \mu K_\backslash$ (Proposition 7.2), and $\varrho_{\mathcal{A}} = \mathbf{E}_{\mathcal{A}/g}/\mathbf{E}_{\mathcal{A}\setminus g} = \mu^2$. Conversely let $\varrho_{\mathcal{A}}$ be a constant λ. Connected tables on at least two marks are single molecules (Proposition 28.3(i)), so their letters are irreducible (Theorem 7.11), and $K_/\Psi_/ = \lambda K_\backslash\Psi_\backslash$ matches the irreducible factors on the two sides up to constant factors. $K_/$ and $K_\backslash$ have different degrees, so $K_/ = \mu\Psi_\backslash$ with a constant μ, positive since both have positive coefficients; comparing monomials, the bases of $\mathcal{A}/g$ are the complements in $\mathcal{E}$ of the bases T of $\mathcal{A}\setminus g$, with $\theta_{(\mathcal{E}\setminus T)+g} = \mu\theta_T$. The degrees give $r_{\mathcal{A}} - 1 = |\mathcal{E}| - r_{\mathcal{A}}$, so $\mathcal{A}/g$ has rank $r_{\mathcal{A}} - 1$ on $2r_{\mathcal{A}} - 1$ marks, the fusion width one; it is fusable by Theorem 30.6(d), $\mathcal{A}$ having $\mathcal{A}/g$ and $\mathcal{A}\setminus g$, with the bases of $(\mathcal{A}/g)^*$, as its children at the full and at the empty pattern of $\{g\}$. By Theorem 30.5(v) its fusion has the letter $K^\sharp = \Psi_/ + \alpha_g K_/ = \mu K_\backslash + \alpha_g K_/$, and $K^\sharp(\alpha_{\mathcal{E}}, \mu\alpha_g) = \mu K_\backslash + \mu\alpha_g K_/ = \mu K_{\mathcal{A}}(\alpha_{\mathcal{E}}, \alpha_g)$: $\mathcal{A}$ has the bases of that fusion, the weights $\theta_{T'+g}$ on the bases $T' + g$ and $\theta_{T'+g}/\mu$ on the bases $\mathcal{E}\setminus T'$, T' a basis of $\mathcal{A}/g$. For a list every coefficient is 1, so $\mu = 1$: the complement in $\mathcal{E}\sqcup\{g\}$ of a basis T avoiding g is the basis $(\mathcal{E}\setminus T) + g$ and conversely, $\mathcal{A}$ is identically self-dual, $\mathcal{A}\setminus g = (\mathcal{A}/g)^*$, and $\mathcal{A}$ is the only major of $\mathcal{A}/g$, its fusion; an identically self-dual $\mathcal{A}$ has the ratio 1, its hinge minors being dual with the same weights. At exponents $s, t > 0$ a ratio is constant exactly when the law is carried by one point, the base form having a positive continuous density on the open simplex (Corollary 23.12(i)). □

Corollary 30.18 (A pinned set of one list is a dual pair). *As stated.*

Proof. By Theorem 28.25, S is pinned exactly when it has width one and $\varrho_S = 1$. The cell of the bunch $\mathcal{B}_S^+$ is a list with the hinge minors $\mathcal{B}|S$ and $\mathcal{B}/S'$ (19.4) and the ratio ϱ_S (21.1). Its hinge minors being connected, its ratio is constant exactly when it is identically self-dual (Proposition 30.17), that is a dual pair (Proposition 21.8(i)), and then the ratio is 1 (Proposition 21.8(ii)). So $\varrho_S = 1$ exactly when $\mathcal{B}_S^+$ is a dual pair, that is $\mathcal{B}/S' = (\mathcal{B}|S)^*$. □

Proposition 30.20 (Cousins). *As stated.*

Proof. (i) is Corollary 30.7(i) with $C = \{x\}$, and its proof gives $\mathcal{B}^\sharp\setminus x = (\mathcal{B}^\sharp/x)^*$; for $x \in G$, $\mathcal{B}^\sharp/x$ is the partial fusion at $G - x$, and at $c = 1$, $\mathcal{B}^\sharp/g = \mathcal{B}$. (ii) Corollary 20.19 at x, which allows every pair of exponents with $s + t = 2\sigma$, gives $P_{\mathcal{B}^\sharp} = \Gamma_{\!\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\begin{bmatrix} m_x,\ 2\sigma - m_x \\ 2\sigma \end{bmatrix} P_{\mathcal{B}^\sharp\setminus x}(\mathbf{m}_{-x}; 2\sigma - m_x, m_x)$, and the dual $\mathcal{B}^\sharp\setminus x$ of $\mathcal{B}^\sharp/x$ has the letters exchanged (Proposition 7.2); the same holds at y. (iii) $K^\sharp(\beta^*\alpha) = K^\sharp(\alpha)$, and the change of coordinates $u \mapsto \beta^* u$ permutes the coordinates of $\Delta_{\mathcal{E}\sqcup G}$ and keeps $d\omega$, so the period at $\beta^*\mathbf{m}$ is the period at $\mathbf{m}$. At $c = 1$ Corollary 30.13 writes $P_{\mathcal{B}^\sharp}$ on its balance wall, where every proper wall is positive, as the stated function of $(\mathbf{m}|_{\mathcal{E}}, s')$, $s' = m_g$; an automorphism permutes the proper walls, $\kappa_U(\beta^*\mathbf{m}) = \kappa_{\beta(U)}(\mathbf{m})$, so it keeps that part of the

hyperplane, and the function inherits the invariance; at $\beta^*\mathbf{m}$ the mass of g is $m_{\beta(g)}$ and the mass of $\beta^{-1}(g)$ is $m_g = s'$. □

Theorem 30.23 (Fusion across a two-sum). *As stated.*

Proof. (i) $\mathcal{S}$ has the rank $r_1 + r_2 - 1$ on $n_1 + n_2 - 2$ marks (Lemma 21.12), so the fusion width $c_1 + c_2$. By Lemma 21.2 its bases are the $X \sqcup Y$ with X a basis of $\mathcal{A}_1 \setminus g$ and Y of $\mathcal{A}_2/g$, or X of $\mathcal{A}_1/g$ and Y of $\mathcal{A}_2 \setminus g$; since independent sets of a table extend to bases inside any set that contains them and has full rank, a set $I_1 \sqcup I_2$ is independent exactly when I_1 and $I_2 + g$ are independent in $\mathcal{A}_1$ and $\mathcal{A}_2$, or $I_1 + g$ and I_2 are. A dependent set inside $\mathcal{E}_1$ is dependent in $\mathcal{A}_1$, $\{g\}$ being independent in $\mathcal{A}_2$, so the circuits inside $\mathcal{E}_1$ are the circuits of $\mathcal{A}_1$ avoiding g, and likewise for $\mathcal{E}_2$. A circuit $C_1' \sqcup C_2'$ meeting both sides contains no such circuit, so C_1' and C_2' are independent; it is dependent exactly when $C_1' + g$ and $C_2' + g$ are dependent, that is when g lies in the closures of C_1' and of C_2'; and removing $e \in C_1'$ leaves an independent set exactly when $C_1' - e + g$ is independent, $C_2' + g$ being dependent. So the minimal ones are those with $C_1' + g$ and $C_2' + g$ circuits, and every such set is a circuit. The complement of $X \sqcup Y$ is $(\mathcal{E}_1 \setminus X) \sqcup (\mathcal{E}_2 \setminus Y)$, and $(\mathcal{A}_1 \setminus g)^* = \mathcal{A}_1^*/g$, $(\mathcal{A}_2/g)^* = \mathcal{A}_2^* \setminus g$, so $\mathcal{S}^* = \mathcal{A}_1^* \oplus_g \mathcal{A}_2^*$, g being neither a loop nor a coloop of $\mathcal{A}_i^*$; its circuits, the cocircuits of $\mathcal{S}$, are read off the same description.

(ii) A cocircuit D of $\mathcal{A}_1$ avoiding g contains no circuit of $\mathcal{A}_2$ and no set $(C_1 \setminus g) \cup (C_2 \setminus g)$, $C_2 \setminus g$ being a nonempty part of $\mathcal{E}_2$; so it is a union of circuits of $\mathcal{S}$ exactly when it is one of $\mathcal{A}_1$, and these cocircuits answer a_1; likewise a_2. For $D = (D_1 \setminus g) \cup (D_2 \setminus g)$ and $e \in D_1 \setminus g$, the circuits of $\mathcal{S}$ inside D through e are the circuits of $\mathcal{A}_1$ inside D_1 avoiding g through e and the sets $(C_1 \setminus g) \cup (C_2 \setminus g)$ with $e \in C_1 \subseteq D_1$ and $C_2 \subseteq D_2$ circuits through g. So e is covered in D exactly when D_1 covers it by a circuit avoiding g, or by one through g while D_2 covers g. D_1 and D_2 run independently over the cocircuits through g. If h_2 holds, the marks of the side $\mathcal{E}_1$ are covered for every D_2 exactly when u_1; if h_2 fails, some D_2 does not cover g, and they are covered exactly when s_1, which implies u_1. So the side $\mathcal{E}_1$ asks u_1 and (s_1 or h_2), the side $\mathcal{E}_2$ asks u_2 and (s_2 or h_1), and Theorem 30.6(b) gives the rule. For one cell, its cocircuits avoiding g answer a, and those through g are unions of circuits exactly when their marks other than g are covered, u, and g is, h. Two fusable cells have a_i, u_i, h_i, and the rule holds.

(iii) By the bases of (i), $r_{\mathcal{S}}(\mathcal{E}_2) = r_2$ and $d_{\mathcal{S}}(\mathcal{E}_2) = r_2 - 1$, so $r^*_{\mathcal{S}}(\mathcal{E}_2) = |\mathcal{E}_2| - d_{\mathcal{S}}(\mathcal{E}_2) = n_2 - r_2$. A fusable $\mathcal{S}$ has $r_{\mathcal{S}} \le r^*_{\mathcal{S}}$ pointwise, $\mathcal{S}$ being a quotient of $\mathcal{S}^*$ (Proposition 30.2(i)): $r_2 \le n_2 - r_2$, $c_2 \ge 0$, and likewise $c_1 \ge 0$. In $\mathcal{S}^\sharp$, $r^\sharp(\mathcal{E}_2) = r^*_{\mathcal{S}}(\mathcal{E}_2) = n_2 - r_2$, the rank of a set avoiding G being its rank in $\mathcal{S}^\sharp \setminus G = \mathcal{S}^*$. An identically self-dual table has $r^*(A) = r(A)$, so $d(A) = |A| - r(A)$ and $c(A) = 2r(A) - |A|$, which for $A = \mathcal{E}_2$ is $2(n_2 - r_2) - (n_2 - 1) = c_2 + 1$; likewise for $\mathcal{E}_1$.

(iv) In $\mathcal{A}_i^\sharp$ the mark g lies in a basis $X \sqcup G_i$, X a basis of $\mathcal{A}_i$ through g, and avoids a basis X of $\mathcal{A}_i^*$, so $\mathcal{A}_i^\sharp$ is a cell with the hinge g and $W = \mathcal{A}_1^\sharp \oplus_g \mathcal{A}_2^\sharp$ is a table on $\mathcal{E}_1 \sqcup \mathcal{E}_2 \sqcup G_1 \sqcup G_2$. By (i) $W^* = \mathcal{A}_1^{\sharp *} \oplus_g \mathcal{A}_2^{\sharp *} = W$. Contracting $G = G_1 \sqcup G_2$ commutes with the minors at g, marks of different sets (Definition 7.5), so the bases of W containing G, less G, are those of $(\mathcal{A}_1^\sharp/G_1) \oplus_g (\mathcal{A}_2^\sharp/G_2) = \mathcal{S}$, and likewise $W \setminus G = \mathcal{A}_1^* \oplus_g \mathcal{A}_2^* = \mathcal{S}^*$: W is an identically self-dual major. If $c_2 = 0$, $\mathcal{A}_2$ is a quotient of $\mathcal{A}_2^*$ of the same rank, so the two rank functions agree (Proposition 30.2(i) at $X \subseteq Y$ and at $Y \subseteq \mathcal{E}$) and $\mathcal{A}_2 = \mathcal{A}_2^* = \mathcal{A}_2^\sharp$; every transposition of two marks of G_1 carries $\mathcal{A}_1^\sharp$, hence W, and $W = \mathcal{S}^\sharp$ by Theorem 30.5(iv); likewise for $c_1 = 0$. Let $c_1, c_2 \ge 1$, $x_1 \in G_1$, $x_2 \in G_2$, and let $r_1^* = n_1 - r_1$, the rank of $\mathcal{A}_1^\sharp$. A basis $Z_1 \sqcup Z_2$ of W has $|Z_1| \in \{r_1^*, r_1^* - 1\}$. At the pattern $\{x_1\}$ of G, $|Z_1 \cap \mathcal{E}_1| = |Z_1| - 1 \le r_1^* - 1$, with equality for $Z_1 = X_1 \sqcup \{x_1\}$, X_1 a basis of $\mathcal{L}_{c_1-1}(\mathcal{A}_1^*, \mathcal{A}_1)$ avoiding g, and $Z_2 = X_2 - g$, X_2 a basis of $\mathcal{A}_2^*$ through g; such bases exist, g being independent in $\mathcal{A}_1$ and so in its lift $\mathcal{L}_1 = \mathcal{L}^*_{c_1-1}$, and not a loop of $\mathcal{A}_2^*$. At the pattern $\{x_2\}$, Z_1 a basis of $\mathcal{A}_1^*$

avoiding g and $Z_2 = (X_2 \sqcup \{x_2\}) - g$, X_2 a basis of $\mathcal{L}_{c_2-1}(\mathcal{A}_2^*, \mathcal{A}_2)$ through g, give $|Z_1 \cap \mathcal{E}_1| = r_1^*$. So the two children have the ranks $r_1^* - 1$ and r_1^* on $\mathcal{E}_1$, they differ, and G is not in level form in W, while it is in $\mathcal{S}^\sharp$.

(v) If both cells are fusable, $\mathcal{S}$ is fusable by (ii), and for $c_2 = 0$ the fusable list $\mathcal{A}_2$ of the width zero equals its dual, as in (iv), so it is identically self-dual, and $\mathcal{S}^\sharp = \mathcal{A}_1^\sharp \oplus_g \mathcal{A}_2$ by (iv). Conversely let $\mathcal{S}$ be fusable; by (iii) $\{c_1, c_2\} = \{0, 1\}$; let $c_2 = 0$. By (iii) $\mathcal{E}_2$ is a bunch of width one of $\mathcal{S}^\sharp$, a list, and by Theorem 19.4 and Proposition 21.3(iii) $\mathcal{S}^\sharp$ is the two-sum of the cell $\mathcal{N}_2$ of the bunch $\mathcal{E}_2$ and the cell $\mathcal{N}_1$ of its room $\mathcal{E}_1 \sqcup G$, along a hinge h. The cell of $\mathcal{E}_2$ in the dual table has the bases $\mathcal{S}^{\sharp *}|\mathcal{E}_2 = (\mathcal{S}^\sharp/(\mathcal{E}_1 \sqcup G))^*$ and $\mathcal{S}^{\sharp *}/(\mathcal{E}_1 \sqcup G) + h = (\mathcal{S}^\sharp|\mathcal{E}_2)^* + h$, the complements in $\mathcal{E}_2 + h$ of the bases of $\mathcal{N}_2$; $\mathcal{S}^\sharp$ being identically self-dual, $\mathcal{N}_2$ is. In $\mathcal{S} = \mathcal{S}^\sharp/G$ the cell of $\mathcal{E}_2$ is $\mathcal{A}_2$ (Lemma 21.2); its bases through the hinge, $\mathcal{S}/\mathcal{E}_1 = \mathcal{S}^\sharp/(\mathcal{E}_1 \sqcup G)$, are those of $\mathcal{N}_2$, and its bases avoiding the hinge are those of $(\mathcal{S}^\sharp/G)|\mathcal{E}_2$. Here $r^\sharp(\mathcal{E}_2) = n_2 - r_2 = r_2$ by (iii) and $c_2 = 0$, while $r^\sharp(\mathcal{E}_2 \sqcup G) = r_{\mathcal{S}}(\mathcal{E}_2) + |G| = r_2 + |G|$; by submodularity every independent $I \subseteq \mathcal{E}_2$ of $\mathcal{S}^\sharp$ has $r^\sharp(I \sqcup G) \geq |I| + r^\sharp(\mathcal{E}_2 \sqcup G) - r^\sharp(\mathcal{E}_2) = |I| + |G|$, so $(\mathcal{S}^\sharp/G)|\mathcal{E}_2 = \mathcal{S}^\sharp|\mathcal{E}_2$ and $\mathcal{A}_2 = \mathcal{N}_2$, identically self-dual. The cell of the room $\mathcal{E}_1$ in $\mathcal{S}$ has the bases of $\mathcal{S}|\mathcal{E}_1 = (\mathcal{S}^\sharp|(\mathcal{E}_1 \sqcup G))/G$ and of $\mathcal{S}/\mathcal{E}_2 + h = (\mathcal{S}^\sharp/\mathcal{E}_2)/G + h$, so $\mathcal{A}_1 = \mathcal{N}_1/G$; $\mathcal{N}_1$ is identically self-dual by the same argument as $\mathcal{N}_2$, so $\mathcal{N}_1 \setminus G = (\mathcal{N}_1/G)^*$ and $\mathcal{N}_1$ is a major of $\mathcal{A}_1$: $\mathcal{A}_1$ is fusable (Theorem 30.6), of the width $|G| = 1$, and $\mathcal{N}_1 = \mathcal{A}_1^\sharp$ (Theorem 30.5(v)). So $\mathcal{S}^\sharp = \mathcal{A}_1^\sharp \oplus_g \mathcal{A}_2$, as (iv) also gives: $\mathcal{S}^\sharp$ is the two-sum along the hinge g of $\mathcal{S}$, with $\mathcal{E}_2$ a bunch of width one. □

Corollary 30.24 (A two-sum with an identically self-dual cell). *As stated.*

Proof. Every proper wall of $\mathcal{S}$ positive makes $P_{\mathcal{S}}$ finite (Theorem 8.7); κ and $2\sigma - \kappa$ are the walls of $\mathcal{S}$ at $\mathcal{E}_1$ and $\mathcal{E}_2$ (Lemma 21.12), so $0 < \kappa < 2\sigma$. $\mathcal{A}_1$ is identically self-dual, so $\mathcal{A}_1/g$ is the dual of $\mathcal{A}_1 \setminus g$ with the same weights, its ratio is 1, and $\phi_{\mathcal{A}_1}(\Delta_{\mathcal{E}_1}) = P_{\mathcal{A}_1 \setminus g}(\mathbf{m}|_{\mathcal{E}_1}; \kappa, 2\sigma - \kappa)$ (Corollary 23.12(ii)), finite since $\mathcal{A}_1$ sits in a gluing of finite period. By Corollary 23.12(i) $\mathcal{A}_1$ acts in $\mathcal{S}$ as this number times the one-mark cell of ratio 1 and mass κ, whose two-sum with $\mathcal{A}_2$ is $\mathcal{A}_2$ with its hinge carrying κ: $P_{\mathcal{S}} = \phi_{\mathcal{A}_1}(\Delta_{\mathcal{E}_1})\, P_{\mathcal{A}_2}(\mathbf{m}|_{\mathcal{E}_2}, \kappa; s, t)$. The Beta corner of Corollary 23.12(iii) at g with the mass $2\sigma - \kappa$, which puts $\mathcal{A}_1$ on its balance wall (Lemma 21.12), is the integral over the scale of g, valid in $[0, \infty]$ for $0 < \kappa < 2\sigma$ by Tonelli: $P_{\mathcal{A}_1}(\mathbf{m}|_{\mathcal{E}_1}, 2\sigma - \kappa; s, t) = \Gamma_{\begin{smallmatrix} 2 \\ 1 \end{smallmatrix}} \begin{bmatrix} 2\sigma - \kappa, & \kappa \\ & 2\sigma \end{bmatrix} P_{\mathcal{A}_1 \setminus g}(\mathbf{m}|_{\mathcal{E}_1}; \kappa, 2\sigma - \kappa)$. When the cells are lists and $\mathcal{A}_2$ is fusable of the fusion width one, $\mathcal{A}_1$, identically self-dual, is fusable of the width zero, and Theorem 30.23(v), with the roles of the two cells exchanged, gives $\mathcal{S}^\sharp = \mathcal{A}_1 \oplus_g \mathcal{A}_2^\sharp$. □

Proposition 30.25 (Uncovered marks and repair). *As stated.*

Proof. (i) A cocircuit is a union of circuits exactly when it covers each of its marks, so $\mathcal{B}$ has no uncovered mark exactly when (b) of Theorem 30.6 holds, equivalently (a). By that theorem a list, or a table of the width $c \geq 1$, is fusable exactly when (a) holds; at $c < 0$ neither (a) holds nor is the table fusable; and at $c = 0$ the table is fusable exactly when it is identically self-dual (Definition 30.4). (ii) By Theorem 21.6(i) and (ii), under the first rule alone $\mathcal{B}_S$ has $n + |S|$ marks, the rank r and the rank function $Y \mapsto r(\lceil Y \rceil)$, $\lceil Y \rceil$ the marks of $\mathcal{B}$ whose blocks meet Y. So Y is independent exactly when it meets each block in at most one mark and $\lceil Y \rceil$ is independent: the circuits of $\mathcal{B}_S$ are the pairs $\{h, h'\}$, $h \in S$, and the sets meeting each block in at most one mark whose shadow $\lceil \cdot \rceil$ is a circuit of $\mathcal{B}$. A closed set contains with a mark its whole block, adding a mark of a block already met not raising the rank; so the closed sets are the unions of the blocks over the closed sets of $\mathcal{B}$, and since the cocircuits are the complements of the closed sets of rank $r - 1$ (fact (β) in the proof of Theorem 30.6) the cocircuits of $\mathcal{B}_S$ are $D^+ = D \cup \{h' : \ h \in D \cap S\}$,

D a cocircuit of $\mathcal{B}$. In D^+ the marks h, h' of a block are covered by $\{h, h'\}$, and a mark $e \in D \setminus S$ is covered exactly when a circuit of $\mathcal{B}_S$ through e lies in D^+, that is when a circuit of $\mathcal{B}$ through e, its shadow, lies in D. So $\mathcal{B}_S$ has no uncovered mark exactly when every mark of $\mathcal{E} \setminus S$ is covered in every cocircuit of $\mathcal{B}$ through it: when S contains the uncovered marks; and by (i) for $\mathcal{B}_S$, a list or a table of the width $c + |S| \neq 0$, it is then fusable exactly when it has no uncovered mark. Its fusion width is $n + |S| - 2r$. The bases of $\mathcal{B}_S$ avoiding S' are the bases T of $\mathcal{B}$, each with its weight θ_T (Theorem 21.5), so $(\mathcal{B}_S, \theta) \setminus S' = (\mathcal{B}, \theta)$. (iii) $(\mathcal{B}_S)^\sharp/G = (\mathcal{B}_S, \theta)$ and $(\mathcal{B}_S, \theta) \setminus S' = (\mathcal{B}, \theta)$, the two minors being taken at disjoint sets. Let $c \geq 0$, $(\mathcal{B}, \theta)$ not fusable, and U its set of uncovered marks, none a loop, since a loop lies in no cocircuit. If $U \neq \varnothing$, $S = U$ gives the width $c + |U| \geq 1$ and no uncovered mark, and $\mathcal{B}_U$ is fusable by (ii). If $U = \varnothing$, (i) leaves $c = 0$ and $(\mathcal{B}, \theta)$ not identically self-dual, while $\mathcal{B} = \mathcal{B}^*$ by (a) and the proof of Definition 30.4; a loop of $\mathcal{B}$ would be a coloop of $\mathcal{B}^* = \mathcal{B}$, so there is none, and $\mathcal{E} \neq \varnothing$, since on no marks the one basis $\varnothing$ is its own complement with its own weight. For any mark h, $S = \{h\}$ gives the width one and no uncovered mark, and $\mathcal{B}_S$ is fusable by (ii). For a list $\mathcal{B}$, the set of the marks that are not loops contains U, and the list $\mathcal{B}_S$ it doubles has no uncovered mark and is fusable by (i). (iv) The copy h' is neither a loop nor a coloop, so its wall at $t = 0$ is $\kappa_{\{h'\}} = m_{h'}$. Theorem 16.25 at the bunch $\{h'\}$, whose bottom level holds the bases avoiding h', with the empty pattern alone, so that the weights factor on it, gives the residue as the product of the periods of the faces: on $\{h'\}$ the contraction of the room, of rank $d(\{h'\}) = 0$ and letter 1, whose period on one mark is 1; on the room, $(\mathcal{B}_S|(\mathcal{E}_S \setminus h'); s, 0) = (\mathcal{B}_{S-h}; s, 0)$. □

50.31 Chapter 31: closing a glue along a direction

Theorem 31.2 (Closing the glue along a direction). *As stated, the largest values of the monomials of the letter vector of the partner being read on its law when its room word has a Newton sum of full dimension.*

Proof. Apart from the sentence on the partner, the statement is the reference's, with its proof (the reference, proof of thm:closecone). Let the room word of the partner have a Newton sum of full dimension. The partner is a piece on R with the stations $\mathcal{D}$, read with the reversed excesses $c_j - i(D)$ (28.4); its scale γ_R^ρ and its seam vector $\boldsymbol{\varrho}_R^\rho = (\varrho_{R,jD}^\rho, \varrho_{R,jD}^{\rho *})_{j,D}$ are those of 28.5 with its room letters and these excesses. In this proof write $L_{j,R}^{(0)}$ for the sum of the L_{jD} over the stations of excess c_j, which have the reversed excess 0, and $L_{j,R}^{*(c)}$ for the sum of the L_{jD}^* over the stations of excess 0, which have the reversed excess c_j. By 28.5,

$$L_{jD} = L_{j,R}^{(0)} \, (\gamma_R^\rho)^{c_j - i(D)} \, \varrho_{R,jD}^\rho, \qquad L_{jD}^* = L_{j,R}^{*(c)} \, (\gamma_R^\rho)^{i(D)} \, \varrho_{R,jD}^{\rho *}.$$

A direction $\mathbf{v} \in V$ keeps the letter totals, $\sum_D v_{jD} = 0$ and $\sum_D v_{jD}^* = 0$ for every active letter. It also keeps the pin of 28.12 for every vector of M, the pin of $\mathbf{1}$ holding by the letter totals on the balance wall, and $\mathbf{1}_R \in \vec{\mathcal{N}}_R^\perp \subseteq M$, the room letters being homogeneous. The exponents in $\mathbf{n}(\mathbf{a}, \mathbf{b})$ of the monomials of V_{jD} and V_{jD}^* vanish on R, and those of the monomials of L_{jD} and L_{jD}^* have the totals $\deg L_{jD} = e_j + c_j - i(D)$ and $\deg L_{jD}^* = e_j^* + i(D)$ on R (28.4); so, by the letter totals,

$$0 = \langle \mathbf{n}(\mathbf{v}), \mathbf{1}_R \rangle = \sum_{j,D} \big(v_{jD} \deg L_{jD} + v_{jD}^* \deg L_{jD}^* \big) = \sum_{j,D} \big((c_j - i(D)) v_{jD} + i(D) v_{jD}^* \big).$$

So in $\mathbf{V}_R^\mathbf{v} = \prod_{j,D} L_{jD}^{v_{jD}} {L_{jD}^*}^{v_{jD}^*}$ the sums $L_{j,R}^{(0)}$ and $L_{j,R}^{*(c)}$ and the scale γ_R^ρ enter with the exponent 0, and $\mathbf{V}_R^\mathbf{v} = (\boldsymbol{\varrho}_R^\rho)^\mathbf{v}$ on the open orthant of R, where these sums are positive, both sides being homogeneous of degree zero; hence $\sup \mathbf{V}_R^\mathbf{v} = \sup_{v \in \Delta_R} \boldsymbol{\varrho}_R^\rho(v)^\mathbf{v}$, the supremum over the open simplex.

The scale form ϕ_R^ρ has a positive continuous density on the open simplex and the seam vector is continuous there, so the law $(\boldsymbol{\varrho}_R^\rho)_*\phi_R^\rho$ is carried by the closure of the image of the open simplex, and every point of that image lies in its support: the preimage of a neighbourhood of an image point is a nonempty open set, of positive mass. The supremum of the continuous function $\mathbf{x}^{\mathbf{v}}$ over the image is therefore its largest value on the support of the law, in $(0,\infty]$. □

Lemma S14. *Let $L_1,\dots,L_p$ be positive letters on a finite set B (25.1), $e_0\in B$, $e_1,\dots,e_p$ real exponents and $\mathbf{m}$ real masses on B with $m_B=\sum_\ell e_\ell \deg L_\ell$; the pairings below are taken on $B\setminus e_0$.*

(i) There are finitely many rational simplicial cones of dimension $|B|-1$ with disjoint interiors covering $\mathbb{R}^{B\setminus e_0}$, each contained, for every ℓ, in a set $\{\mathbf{v}:\ \langle\mathbf{t},\mathbf{v}\rangle\le\langle\mathbf{t}',\mathbf{v}\rangle$ for every exponent $\mathbf{t}'$ of the support of $L_\ell\}$ for one exponent $\mathbf{t}$ of that support.

(ii) On such a cone π, with the primitive integral generators $\mathbf{v}_{\pi,1},\dots,\mathbf{v}_{\pi,|B|-1}$, write $x=\log\alpha_{B\setminus e_0}=-\sum_k u_k\mathbf{v}_{\pi,k}$ on the section $\alpha_{e_0}=1$, $u_k\ge0$, and $q_k=e^{-u_k}$. The exponent $\mathbf{t}_{\ell,\pi}$ of (i) is unique, and $L_\ell=\prod_k q_k^{\langle\mathbf{t}_{\ell,\pi},\mathbf{v}_{\pi,k}\rangle}\,k_{\ell,\pi}(q)$ on the section, with $k_{\ell,\pi}$ a polynomial in q with nonnegative coefficients whose constant term is the coefficient of $\alpha^{\mathbf{t}_{\ell,\pi}}$ in L_ℓ.

(iii) For a generator $\mathbf{v}$ of π the number $\kappa_{\mathbf{v}}=\langle\mathbf{m}-\sum_\ell e_\ell\mathbf{t}_{\ell,\pi},\mathbf{v}\rangle$ is the same for every cone π of which $\mathbf{v}$ is a generator, and, in $[0,\infty]$,

$$\int_{\alpha_{e_0}=1}\alpha^{\mathbf{m}-\mathbf{1}}\prod_\ell L_\ell^{-e_\ell}\,d\alpha_{B\setminus e_0}$$
$$=\sum_\pi|\det(\mathbf{v}_{\pi,1},\dots,\mathbf{v}_{\pi,|B|-1})|\int_{[0,1]^{|B|-1}}\prod_k q_k^{\kappa_{\mathbf{v}_{\pi,k}}-1}\prod_\ell k_{\ell,\pi}(q)^{-e_\ell}\,dq;$$

both sides are finite exactly when every $\kappa_{\mathbf{v}}$ is positive, and they are then the period of the word $\prod_\ell L_\ell^{-e_\ell}$ at $\mathbf{m}$, the integral over a section of 25.1.

Proof. (i) Identify $\mathbb{R}^{B\setminus e_0}$ with the hyperplane $v_{e_0}=0$ of $\mathbb{R}^B$. For each ℓ the sets $C_{\ell,\mathbf{t}}=\{\mathbf{v}:\ \langle\mathbf{t},\mathbf{v}\rangle\le\langle\mathbf{t}',\mathbf{v}\rangle$ for every $\mathbf{t}'\}$, $\mathbf{t}$ in the support of L_ℓ, are rational polyhedral cones, defined by the inequalities $\langle\mathbf{t}-\mathbf{t}',\mathbf{v}\rangle\le0$: the cones of the inner normal fan of the Newton polytope of L_ℓ cut by that hyperplane, which form a fan covering $\mathbb{R}^{B\setminus e_0}$, every $\mathbf{v}$ having an exponent of least pairing. The cones $\bigcap_\ell C_{\ell,\mathbf{t}_\ell}\cap O$, O running over the closed coordinate orthants of $\mathbb{R}^{B\setminus e_0}$, are pointed rational polyhedral cones which with their faces form a fan covering $\mathbb{R}^{B\setminus e_0}$, the common refinement of these fans and of the fan of the orthants. Order its rays and triangulate each cone by pulling: the cone is the union of the cones spanned by its first ray and by the triangulated faces that do not contain that ray. A face F of a pointed cone C has $\operatorname{span}F\cap C=F$, so the first ray of C lies off $\operatorname{span}F$ for such a face, and the cones produced are simplicial; the pulling triangulation of a cone restricts on each face to the pulling triangulation of that face, which depends on the face alone, so the triangulations of two cones agree on their common face. This gives finitely many rational simplicial cones of dimension $|B|-1$ with disjoint interiors covering $\mathbb{R}^{B\setminus e_0}$, each in some $\bigcap_\ell C_{\ell,\mathbf{t}_\ell}$.

(ii) If $\mathbf{t}$ and $\mathbf{t}''$ both pair least with every $\mathbf{v}_{\pi,k}$, then $\langle\mathbf{t}-\mathbf{t}'',\mathbf{v}_{\pi,k}\rangle=0$ for every k; the generators span $\mathbb{R}^{B\setminus e_0}$, so $\mathbf{t}$ and $\mathbf{t}''$ agree on $B\setminus e_0$, and as $|\mathbf{t}|=|\mathbf{t}''|=\deg L_\ell$ they are equal. On the section $\alpha^{\mathbf{t}'}=e^{\langle\mathbf{t}',x\rangle}=\prod_k q_k^{\langle\mathbf{t}',\mathbf{v}_{\pi,k}\rangle}$, so with $L_\ell=\sum_{\mathbf{t}'}c_{\mathbf{t}'}\alpha^{\mathbf{t}'}$ and $\mathbf{t}=\mathbf{t}_{\ell,\pi}$,

$$L_\ell=\prod_k q_k^{\langle\mathbf{t},\mathbf{v}_{\pi,k}\rangle}\sum_{\mathbf{t}'}c_{\mathbf{t}'}\prod_k q_k^{\langle\mathbf{t}'-\mathbf{t},\mathbf{v}_{\pi,k}\rangle}.$$

Every exponent $\langle \mathbf{t}' - \mathbf{t}, \mathbf{v}_{\pi,k} \rangle$ is an integer, the exponents and the generators being integral, and it is nonnegative by the choice of $\mathbf{t}$; by the uniqueness just proved, all of them vanish only at $\mathbf{t}' = \mathbf{t}$. So the sum is a polynomial $k_{\ell,\pi}$ with nonnegative coefficients and the constant term $c_{\mathbf{t}} > 0$.

(iii) A cone π of which $\mathbf{v}$ is a generator has $\langle \mathbf{t}_{\ell,\pi}, \mathbf{v} \rangle = \min_{\mathbf{t}'} \langle \mathbf{t}', \mathbf{v} \rangle$, the minimum over the support of L_ℓ, which does not depend on π; so neither does $\kappa_{\mathbf{v}}$. On π the map $(u_k)_k \mapsto x = -\sum_k u_k \mathbf{v}_{\pi,k}$ is a linear bijection of $[0,\infty)^{|B|-1}$ onto $-\pi$ with the Jacobian $|\det(\mathbf{v}_{\pi,1}, \dots, \mathbf{v}_{\pi,|B|-1})|$; on the section $d\alpha_e = \alpha_e \, dx_e$ for $e \neq e_0$, $\alpha^{\mathbf{m}} = e^{\langle \mathbf{m}, x \rangle}$, and $du_k = -dq_k/q_k$. By (ii), on the image of $-\pi$, the form $\alpha^{\mathbf{m}-\mathbf{1}} \prod_\ell L_\ell^{-e_\ell} \, d\alpha_{B \setminus e_0} = e^{\langle \mathbf{m}, x \rangle} \prod_\ell L_\ell^{-e_\ell} \, dx$ is

$$|\det(\mathbf{v}_{\pi,1}, \dots, \mathbf{v}_{\pi,|B|-1})| \prod_k q_k^{\langle \mathbf{m} - \sum_\ell e_\ell \mathbf{t}_{\ell,\pi}, \mathbf{v}_{\pi,k} \rangle - 1} \prod_\ell k_{\ell,\pi}(q)^{-e_\ell} \, dq.$$

The cones $-\pi$, like the cones π, cover $\mathbb{R}^{B \setminus e_0}$ with disjoint interiors, their boundaries are null and the integrands are positive, so the two sides agree in $[0,\infty]$ (Tonelli's theorem). On $[0,1]^{|B|-1}$ each $k_{\ell,\pi}$ lies between its constant term and the sum of its coefficients, so $\prod_\ell k_{\ell,\pi}^{-e_\ell}$ is bounded above and below by positive constants, and the integral over the cube is finite exactly when every exponent $\kappa_{\mathbf{v}_{\pi,k}}$ is positive; every generator is a generator of some cone. The form $\alpha^{\mathbf{m}-\mathbf{1}} \prod_\ell L_\ell^{-e_\ell} d\alpha$ is projective, the masses lying on the balance hyperplane, and α_{e_0} is positive and homogeneous of degree one, so the integral over the section is the period (25.1, 16.2). □

Theorem 31.4 (Closing past the walls). *As stated, for every piece whose seam function converges at a real point of the pins of the seam with positive shares, with the sector form of (ii) for every fan of the seam word and with part (iv).*

Proof. The hypothesis. At a real point of the pins with positive shares the seam word $W_B(\mathbf{a}, \mathbf{b})$ is a Newton word (25.1), and the masses $\mathbf{m}_B$ lie on its balance hyperplane: by the letter totals and the scale pin,

$$\sum_{j,D} \Big(a_{jD}\big(d_j + i(D)\big) + b_{jD}\big(d_j^* + c_j - i(D)\big) \Big) = \sum_j \big(s_j d_j + t_j d_j^* \big) + \kappa_B = m_B$$

(28.4, 28.7). Its period, the seam function, converges there, so its Newton sum has the dimension $|B| - 1$ (25.2).

(i). The reference proves (i) for a piece of tables (the reference, proof of thm:pastwalls(i)). Of the piece it uses only that its seam word has a Newton sum of full dimension, so that its reduced period in 28.12 is its seam function at the sums over the monomials, the seam letters repeating over the monomials of the partner; the reference obtains that fact from the connectedness of the family of tables, and here it is the hypothesis. The rest of that proof concerns the partner, whose room letters are read in their monomials, so that $\vec{\mathcal{N}}_R = 0$ and its reduced period is $\prod \xi^{-\mathbf{a}} \prod \xi^{*-\mathbf{b}}$ (28.12); with $M = \mathbb{R}\mathbf{1}_B \oplus \mathbb{R}^R$ and the lattice basis $\mathbf{1}$, $\mathbf{e}_r$ ($r \in R$), the pins of 28.12 are the displayed ones, the scale pin following by the balance.

(ii), the sector form. On the pins of the seam the exponents $\bar{a}_{jD}$, $\bar{b}_{jD}$ of the seam word are affine in the shares with rational linear parts, and the masses $\mathbf{m}_B$ lie on its balance hyperplane at every share, by the display above with the sums in place of the shares. Lemma S14, applied to the seam letters of the active letters with the exponents $\bar{a}_{jD}$, $\bar{b}_{jD}$, gives the fans of the seam word, the sector coordinates, the sector letters with their exponents, the walls and the identity at every real point of the pins, and shows that the seam function converges at a real point exactly when every wall is positive there. The coefficients $\langle \mathbf{t}_{jD,\pi}, \mathbf{v} \rangle$ and $\langle \mathbf{t}^*_{jD,\pi}, \mathbf{v} \rangle$ of the shares in a wall

are integers, so the wall is affine with a rational linear part, and it does not depend on the sector (Lemma S14(iii)).

(ii), continuation and bound. On a sector the integrand is $\prod_k q_k^{\kappa_{\mathbf{v}_{\pi,k}}(\mathbf{z})-1} h(q,\mathbf{z})$ with $h = \prod_{j,D} k_{jD,\pi}^{-\bar a_{jD}} \psi_{jD,\pi}^{-\bar b_{jD}}$. The sector letters are at least their positive constant terms on the closed cube, so their real parts are positive on a neighbourhood of it, where their principal logarithms are holomorphic; so h is holomorphic in q near $[0,1]^{|B|-1}$ and entire in the shares. 8.4, with $x_k = \kappa_{\mathbf{v}_{\pi,k}}(\mathbf{z})$ and the shares as its parameter, continues each sector integral meromorphically to all complex shares, with its poles on the hyperplanes on which a wall of a generator of the sector lies in $-\mathbb{N}$; a wall constant on the pins is positive there, the seam function converging, and gives no hyperplane. The formula of 8.4, repeated in the $|B|-1$ coordinates, writes each term with at most $|B|-1$ factors $(\kappa_{\mathbf{v}_{\pi,k}}+l)^{-1}$, which bounds the orders of the poles by $|B|-1$. For the bound, the proof of 20.32 is run on each sector integral with the several parameters entering through the powers of the sector letters and through the walls, $|\operatorname{Re}\mathbf{z}|_1$ and $|\operatorname{Im}\mathbf{z}|_1$ in place of $|\operatorname{Re} z|$ and $|\operatorname{Im} z|$ (the reference, proof of thm:pastwalls(ii)): each of the at most $|B|-1$ factors $(\kappa+l)^{-1}$ of a term is at most a constant times δ^{-1}, and nothing else depends on δ.

(ii), a piece of tables. Let the seam letters at the station D of the active letters be the basis and the cobasis polynomials of a table $\mathcal{B}_{jD}$ on B with positive weights, and consider the family of these tables at the exponents $\bar a_{jD}, \bar b_{jD}$ at a point with positive shares. Its potential $\sum_{j,D} \left(\bar a_{jD} \log K_{\mathcal{B}_{jD}}(e^y) + \bar b_{jD} \log \Psi_{\mathcal{B}_{jD}}(e^y)\right)$ (8.18) is affine along a direction $\mathbf{w}$ exactly when, in every letter, all the exponents of the support have one pairing with $\mathbf{w}$, a logarithm of a sum of exponentials with positive coefficients being strictly convex along every direction that separates two of its exponents: exactly when $\mathbf{w}$ is orthogonal to the directions of the Newton sum. If the family is connected, that space is $\mathbb{R}\mathbf{1}$ (8.19(iii), a space that does not involve the masses), and the Newton sum has the dimension $|B|-1$. If it is not, some nonempty proper $S \subset B$ has the width $c_{jD}(S) = 0$ in every table (8.1), so that $|T \cap S| = d_{jD}(S)$ for every basis T of $\mathcal{B}_{jD}$ (7.13). The base polytope of $\mathcal{B}_{jD}$ then lies in $\{x_S = d_{jD}(S)\}$ and that of its dual in $\{x_S = |S| - d_{jD}(S)\}$, so the Newton sum lies in a hyperplane $\{x_S = \text{const}\}$, and as $\mathbf{1}_S \notin \mathbb{R}\mathbf{1}$ its dimension is less than $|B|-1$.

In the coordinates of 8.5(ii) on the sector H_π of an order π of B, $\alpha_{\pi(1)} = \rho$ and $\alpha_{\pi(k)} = \rho q_2 \cdots q_k$, so that, with $u_k = -\log q_k$,

$$\log \alpha_{\pi(m)} - \log \alpha_{\pi(1)} = \sum_{k=2}^{m} \log q_k = -\sum_{k=2}^{|B|} u_k \, (\mathbf{1}_{U_k})_{\pi(m)},$$

because $\pi(m) \in U_k$ exactly when $k \le m$. So, modulo $\mathbf{1}$, H_π is the cone with the generators $\mathbf{1}_{U_k}$, $2 \le k \le |B|$, read on the section as $\mathbf{1}_{U_k} - (\mathbf{1}_{U_k})_{e_0}\mathbf{1}$. These $|B|-1$ vectors form a basis of $\mathbb{Z}^B/\mathbb{Z}\mathbf{1}$, since the differences $\mathbf{1}_{U_k} - \mathbf{1}_{U_{k+1}} = \mathbf{e}_{\pi(k)}$ and $\mathbf{1}_{U_1} = \mathbf{1}$ span $\mathbb{Z}^B$; so the cone is simplicial of dimension $|B|-1$ with the determinant ± 1, and the sectors of the orders cover $\mathbb{R}^B/\mathbb{R}\mathbf{1}$ with disjoint interiors. For a basis T, $\alpha^T/\alpha^{T_\pi^+} = \prod_k q_k^{|T\cap U_k| - |T_\pi^+ \cap U_k|}$, and 8.3, $\alpha^T \le \alpha^{T_\pi^+}$ on H_π for every basis, gives, with one q_k small and the others 1, $\langle \mathbf{1}_{T_\pi^+}, \mathbf{1}_{U_k}\rangle \le \langle \mathbf{1}_T, \mathbf{1}_{U_k}\rangle$ for every k. As $\mathbf{1}_T$ and $\mathbf{1}_{T_\pi^+}$ have one total, their pairings on $B \setminus e_0$ with the generator $\mathbf{1}_{U_k} - (\mathbf{1}_{U_k})_{e_0}\mathbf{1}$ differ by the difference of their pairings with $\mathbf{1}_{U_k}$. So the sector lies in the set of (ii) for $K_{\mathcal{B}_{jD}}$ with $\mathbf{t} = \mathbf{1}_{T_\pi^+}$, and likewise for $\Psi_{\mathcal{B}_{jD}}$ with $\mathbf{t} = \mathbf{1}_{B\setminus T_\pi^-}$, the greedy bases being those of $\mathcal{B}_{jD}$; the sectors of the orders form a fan of the seam word. Its sector letters are $\sum_T \theta_{jD,T} \prod_k q_k^{|T\cap U_k| - d_{jD}(U_k)}$ and their cobasis counterparts, the sector letters of 8.5(ii). The vector $\mathbf{m}_B - \sum_{j,D}(\bar a_{jD}\mathbf{1}_{T^+} + \bar b_{jD}\mathbf{1}_{B\setminus T^-})$ has the total 0 on the pins, so its pairing with the generator of a tail U is its pairing with $\mathbf{1}_U$; by 8.3, $|T^+ \cap U| = d_{jD}(U)$ and $|U \setminus T^-| = d^*_{jD}(U)$, and the wall of that generator is $m_U - \sum_{j,D}(\bar a_{jD} d_{jD}(U) + \bar b_{jD} d^*_{jD}(U))$, the proper wall κ_U. Every nonempty proper U is a tail of some order.

(iii). The reference proves (iii) for a piece of tables (the reference, proof of thm:pastwalls(iii)), using three facts about the piece. The first is the continuation with the bound of (ii). The second is that the seam function converges at a real point exactly when its walls are positive there, so that it converges along a ray along which no wall falls, the walls staying above their positive values at $\bar{\mathbf{c}}$, and diverges past a wall that falls. The third is that at real points it is $\int \mathbf{x}^{-\mathbf{w}}\, d\big((\boldsymbol{\varrho}_B^{\rho})_* \phi_B^{\rho}\big)$, with the scale form positive and continuous on the open simplex and the seam vector continuous there, which with 31.2 gives $g(\boldsymbol{\sigma}; 0) = \sup \mathbf{V}_B^{-\bar{\boldsymbol{\sigma}}}$. The first two are (ii), and the third holds for every piece (28.5, 28.7). The rest of that proof (the Gamma bounds, Stirling's formula with $\sum_l \sigma_l = 0$, the crossings and the null set) does not use the tables.

(iv). The partner is a piece on R read with the reversed excesses. The pins of its seam, the letter totals and its scale pin $\sum_{j,D} \big((c_j - i(D))a_{jD} + i(D)b_{jD}\big) = \kappa_R$, are on the balance wall $\kappa_R = \kappa_B^{\mathrm{top}}$ those of the piece (28.10(iii)), and its seam function converges at $\mathbf{c}$; so (ii) applies to the piece and to the partner. On the share side of 28.10(iii) the integrand at $\mathbf{c} + \tau\boldsymbol{\sigma} + i\boldsymbol{\vartheta}$ is $\prod_{j:\, s_j>0} \Gamma_{|\mathcal{D}_j|}\begin{bmatrix}\mathbf{a}_j \\ s_j\end{bmatrix} \prod_{j:\, t_j>0} \Gamma_{|\mathcal{D}_j|}\begin{bmatrix}\mathbf{b}_j \\ t_j\end{bmatrix}$ times the two seam functions. For $M_B > g_B(\boldsymbol{\sigma}; \theta_B)$ and $M_R > g_R(\boldsymbol{\sigma}; \theta_R)$ the definitions of the growths give C, n_1 and n_2 with

$$\big|P_{W_B}\, P_{W_R}\big| \le C^2 \delta^{-2n_2} (1 + \tau + |\boldsymbol{\vartheta}|)^{2n_1} (M_B M_R)^{\tau} e^{(\theta_B + \theta_R)|\boldsymbol{\vartheta}|_1}$$

for $\tau \ge 0$, δ the smaller of 1 and the distance from the polar hyperplanes of both seam functions. From here the proof of (iii) applies with $\theta = \theta_B + \theta_R < \pi/8$ and $M_B M_R$ in place of M, the coefficients sitting inside the seam functions:

- the contour moves along times at distance at least τ^{-3} from the crossings, where δ^{-2n_2} is a power of τ, and the power of $1 + |\boldsymbol{\vartheta}|$ is absorbed into $e^{\eta|\boldsymbol{\vartheta}|_1}$ with η small;
- a share whose real part x grows has $|\Gamma(x + iy)| e^{\theta|y|} \le \Gamma(x) e^{2\theta^2 x/\pi}$, and a share that falls or stays absorbs $e^{\theta|y|}$ against $e^{-\pi|y|/2}$;
- integrating over the directions of the shares, Stirling's formula and $\sum_l \sigma_l = 0$, by the letter totals, give the factor $e^{\tau(h_{\theta_B, \theta_R}(\boldsymbol{\sigma}) + \epsilon)}$ as $M_B \downarrow g_B$ and $M_R \downarrow g_R$.

The ray crosses the hyperplanes of the falling shares and the hyperplanes on which a falling wall of either word lies in $-\mathbb{N}$, and each crossing adds the fibre integral of the residue of the whole integrand (31.3), a Laurent coefficient where several factors are polar. The pins and the walls of both words have rational linear parts, so crossings on parallel hyperplanes coincide or keep a fixed positive distance. Crossings on hyperplanes that are not parallel, closer than T^{-3} near $\tau = T$, occur only for $\mathbf{c}$ in a set of measure $O(T^{-3})$, summable over T (Borel and Cantelli). The local decay (H1) of 31.3 holds because both seam functions grow at most like $e^{\theta' |\operatorname{Im} \mathbf{z}|_1}$ for every $\theta' > 0$, by (ii), against the decay of the Gammas at bounded real parts. (H2) holds at the times above when $h_{\theta_B, \theta_R}(\boldsymbol{\sigma}) < 0$, and 31.3 gives the closing with the stated bounds.

For the last sentence of (iv), let no wall of the word of a side fall along $\boldsymbol{\sigma}$. Both words have Newton sums of full dimension, their seam functions converging at $\mathbf{c}$ (25.2), so the largest value of $\mathbf{x}^{-\boldsymbol{\sigma}}$ on the support of the law of the side is $\sup \mathbf{V}^{-\boldsymbol{\sigma}}$ of its letter vector (31.2, for the partner by its sentence on the partner). At $\theta = 0$ the proof of (iii), run on that side, gives the growth $\sup \mathbf{V}^{-\boldsymbol{\sigma}}$, finite, and the growth does not increase with the angle, a bound with a smaller angle being a bound with a larger one. On the real ray, where $\boldsymbol{\vartheta} = 0$, the walls stay above their positive values at $\mathbf{c}$, so δ is bounded below there, and the seam function at $\mathbf{c} + \tau\boldsymbol{\sigma}$ is at least a positive constant times $e^{\tau h'}$ for every $h' < \log \sup \mathbf{V}^{-\boldsymbol{\sigma}}$ (the proof of (iii)); so every admissible M, at every angle, is at least $\sup \mathbf{V}^{-\boldsymbol{\sigma}}$. □

Definition 31.5 (Chambers of a closing). As stated, for every fibre integral with finitely many affine polar functions.

Proof. The chamber is convex. If $\boldsymbol{\sigma}', \boldsymbol{\sigma}'' \in C(\boldsymbol{\sigma})$ and $0 \le s \le 1$, then $\partial_{s\boldsymbol{\sigma}'+(1-s)\boldsymbol{\sigma}''}\ell = s\,\partial_{\boldsymbol{\sigma}'}\ell + (1-s)\,\partial_{\boldsymbol{\sigma}''}\ell$ equals $\partial_{\boldsymbol{\sigma}}\ell$ for every polar function that $\boldsymbol{\sigma}$ falls and is nonnegative for every other. The ray of $s\boldsymbol{\sigma}' + (1-s)\boldsymbol{\sigma}''$ consists of the points $s(\mathbf{c}+\tau\boldsymbol{\sigma}') + (1-s)(\mathbf{c}+\tau\boldsymbol{\sigma}'')$ of the convex Ω.

The instances:

- In 31.2 the integrand is the Gammas times the reduced periods of the two words. These are holomorphic where they converge absolutely, on a set convex by Hölder's inequality (the reference, def:chamber). On the pins the integrand of a reduced period at $\mathbf{c}' + \tau\boldsymbol{\sigma}$ is its integrand at $\mathbf{c}'$ times $\mathbf{V}^{-\tau\boldsymbol{\sigma}}$ read at the point of the orthant (the reference, proof of thm:closecone), at most $(\sup \mathbf{V}^{-\boldsymbol{\sigma}})^{\tau}$; so when both suprema are finite a ball about $\mathbf{c}$ inside the set of convergence, translated by $\tau\boldsymbol{\sigma}$, stays inside it, and the ray lies in Ω.
- In 31.4(iii) the seam function continues to all complex shares, with its poles where a wall lies in $-\mathbb{N}$ (31.4(ii)), the walls read through the sums of the shares being affine in the shares.
- For a fibre integral of Gammas and coefficients the integrand $\prod_l \Gamma(a_l)\xi_l^{-a_l}$, up to a constant, is meromorphic on all of $A+iV$ with its poles where a share lies in $-\mathbb{N}$. So the polar functions are the shares, $\Omega = A$, and $\partial_{\boldsymbol{\sigma}'} a_l = \sigma_l'$, which gives the chamber displayed. When the pins fix the total of the shares of every letter, every $\boldsymbol{\sigma}' \in V$ has $\sum_{l\in K_j} \sigma_l' = 0$ and $\sum_{l\in\Psi_j} \sigma_l' = 0$, so on the chamber $0 \le \sigma_l' \le \sum |\sigma_{l'}|$, the sum over the falling shares l' of the letter of l: the chamber is a compact convex polytope.
- A source factor that is a cube integral continued by Reg is meromorphic on all of $A + iV$, with its poles where one of its walls lies in $-\mathbb{N}$ (8.4).

□

Theorem 31.6 (A closing depends only on its chamber). *As stated, for every fibre integral of 31.5 with the local decay (H1) of 31.3.*

Proof. A polar function ℓ that $\boldsymbol{\sigma}$ falls has $\ell(\mathbf{c}+\tau\boldsymbol{\sigma}) = \ell(\mathbf{c}) + \tau\partial_{\boldsymbol{\sigma}}\ell = \ell(\mathbf{c}+\tau\boldsymbol{\sigma}')$. So its hyperplanes $\ell = -n$ are met by the two rays at the same times, and ℓ is constant on the segment joining their points at a time τ. A polar function that $\boldsymbol{\sigma}$ does not fall is not fallen by $\boldsymbol{\sigma}'$ either; it is at least $\ell(\mathbf{c}) > 0$ at both points, hence on the segment, and does not lie in $-\mathbb{N}$ there.

So the two rays meet the same polar hyperplanes at the same times. At a crossing time τ^* the polar hyperplanes through $\mathbf{c} + \tau^*\boldsymbol{\sigma}$ and through $\mathbf{c} + \tau^*\boldsymbol{\sigma}'$ are the same, with $\partial_{\boldsymbol{\sigma}}\ell_H = \partial_{\boldsymbol{\sigma}'}\ell_H$, so (H0) holds along one ray exactly when it holds along the other.

At a time τ that is no crossing, the segment avoids every polar hyperplane at a positive distance and lies in the convex Ω. By (H1) on a compact neighbourhood of the segment in Ω, step (1) of the proof of 31.3 (Cauchy's theorem on rectangles whose horizontal sides vanish by (H1), then Fubini's theorem) equates the fibre integrals through its two ends. A crossing term is the difference of the fibre integrals just before and just after the crossing (step (2) of that proof), so the crossing terms of the two rays at a common crossing are equal. Equal terms and equal remainders carry convergence and bounds from one closing to the other.

The rest is the reference's (the reference, proof of thm:chamber). The integrands of 31.2 and of 31.4(iii) have the local decay (H1), by Stirling's formula and the bounds of their proofs, so the first part applies to them. For every $\epsilon > 0$ some $\boldsymbol{\sigma}' \in C(\boldsymbol{\sigma})$, with some θ in the case of 31.4(iii), has a rate below $h' + \epsilon/2$. The null set of 31.2 is the same for every direction of the chamber, its crossings being those of the falling polar functions, and the bounds of 31.2 or of 31.4(iii) along $\boldsymbol{\sigma}'$

bound the terms and the remainders along $\boldsymbol{\sigma}$. On the chamber the falling shares are fixed, $x \log x$ is convex on $[0,\infty)$, and $\log \sup \mathbf{V}_B^{-\boldsymbol{\sigma}'}$ and $\log \sup \mathbf{V}_R^{-\boldsymbol{\sigma}'}$ are suprema of linear functions of $\boldsymbol{\sigma}'$, so the rate h is convex there. □

Theorem 31.7 (Averaging the laws). *As stated, for every share side whose integrand is the Gammas of the shares times a Laplace transform $\int e^{-\langle \mathbf{a}, y\rangle}\, d\lambda$ of a source measure, the kinds (A) and (B) among them.*

Proof. (i). At a source point ζ the kernel is a fibre integral of Gammas and the positive coefficients $e^{y_l(\zeta)}$: the share side of a Gramma (4.2) divided by the constant $\prod_j \Gamma(s_j) \prod_j \Gamma(t_j)$. At the real point $\mathbf{c}$ the Gammas are integrable over the fibre, $|e^{-\langle \mathbf{c}+i\boldsymbol{\vartheta}, y\rangle}| = e^{-\langle \mathbf{c}, y\rangle}$, and $\int e^{-\langle \mathbf{c}, y\rangle}\, d\lambda < \infty$. So the fibre and the source integrals converge absolutely together, and by Fubini's theorem the fibre integral of the share side is the integral of the kernel against λ. In (A) and (B) that fibre integral is $P_{B \sqcup R}(\mathbf{m})$ (28.10(iii), 31.4(i)). In (A) the kernel is $\Gamma(\kappa_B) \mathsf{Z}_{(\kappa_B, \mathbf{s}, \mathbf{t}); t_{\mathcal{D}}}(\mathbf{x} \circ \mathbf{x}')$ (the reference, proof of thm:pool(i)): each active letter of the stand-in pair of 28.10(ii) is opened by 4.4 with one share per station, and the integral over the scale is the pin of the scale.

The bound on the crossing terms is the reference's (the reference, proof of thm:pool(i)). It uses three things:

- 31.6 for the kernel, whose polar functions are the shares, with $\Omega = A$ and (H1) holding by Stirling's formula, so that the closings along $\boldsymbol{\sigma}$ and along every $\boldsymbol{\sigma}' \in C$ are one series;
- Stirling's formula for the Gammas, uniformly on the compact C, the terms $\tau x \log \tau$ cancelling over each letter by its total;
- at a crossing, the expansion of $e^{-\langle \mathbf{a}, y\rangle} = e^{-\langle \mathbf{c}+\tau\boldsymbol{\sigma}', y\rangle} e^{-i\langle \boldsymbol{\vartheta}', y\rangle} e^{-w\langle \mathbf{e}, y\rangle}$ in the transverse variable w to the order $p-1$, with $|\langle \mathbf{e}, y\rangle| \le C|y|_V$, against the Laurent coefficients of the Gammas, which Cauchy's estimate bounds off the null set.

None of these steps uses the kind of the share side.

(ii). The source points with $y(\zeta) \in S_\lambda$ carry all of λ, and there $h_C(y) \le \hat{h}_C$. By (i) the averaged terms are absolutely convergent integrals, at most $C_\epsilon e^{\tau_k(\hat{h}_C+\epsilon)} \int w\, d(y_* \lambda)$, which is finite by the certificate of 31.7. At each source point the kernel is the sum of its crossing terms before a time T separating the crossings and of the integral left at T (31.3, whose identity at a finite time needs no limit), and that integral is at most $C_\epsilon e^{-\langle \mathbf{c}, y\rangle} e^{T(\hat{h}_C+\epsilon)}$. Integrating against λ, the fibre integral of the share side is the sum of the averaged terms before T up to $C_\epsilon e^{T(\hat{h}_C+\epsilon)} \int e^{-\langle \mathbf{c}, y\rangle}\, d\lambda$; the crossings up to T number $O(T)$, and with $\hat{h}_C + \epsilon < 0$ both the sum and the bound follow. At a crossing point, along some $\boldsymbol{\sigma}' \in C$, inside the set where $\int e^{-\langle \mathbf{a}, y\rangle}\, d\lambda$ converges absolutely, with its derivatives in the shares, Fubini's theorem (the Gammas decaying by Stirling's formula) exchanges the fibre and the source integrals in the crossing term of the share side. The inner integral is then the crossing term of the kernel at that point, which is $\mathcal{R}_k(\zeta)$ by 31.6.

(iii). The function $h(\boldsymbol{\sigma}'; y)$ is continuous, convex in $\boldsymbol{\sigma}'$ on C (the falling coordinates being fixed and $x \log x$ convex on $[0,\infty)$), and affine in y; C is compact and convex. Sion's minimax theorem on $C \times \operatorname{conv} S_\lambda$ gives the identity, the supremum of an affine function over $\operatorname{conv} S_\lambda$ being its supremum over S_λ.

For the reading through the log-support,

$$\Big| \int e^{-\langle \mathbf{c}+\tau\boldsymbol{\sigma}'+i\boldsymbol{\vartheta}, y\rangle}\, d\lambda \Big| \le e^{\tau \sup_{y \in S_\lambda} (-\langle \boldsymbol{\sigma}', y\rangle)} \int e^{-\langle \mathbf{c}, y\rangle}\, d\lambda.$$

With the Gamma bounds of the proof of 31.2, this bounds the closing of the share side along $\boldsymbol{\sigma'}$ at the rate $\sum_l \sigma'_l \log|\sigma'_l| + \sup_{S_\lambda}(-\langle \boldsymbol{\sigma'}, y\rangle) = \sup_{y\in S_\lambda} h(\boldsymbol{\sigma'}; y)$. In (A) and (B) this is the rate $h(\boldsymbol{\sigma'})$ of 31.2 (the reference, proof of thm:pool(iii)):

- the seam words of the sides that are laws have Newton sums of full dimension, their seam functions converging at $\mathbf{c}$ (25.2);
- so the largest values of the monomials of their letter vectors are read on the supports of their laws (31.2; for the partner in (A), its sentence on the partner);
- in (B), $\sup \mathbf{V}_R^{-\boldsymbol{\sigma'}} = \boldsymbol{\xi}^{-\boldsymbol{\sigma'}}$;
- the largest value of $-\langle \boldsymbol{\sigma'}, y\rangle$ on the log-support of a product of laws is the sum of its largest values on the log-supports of the factors.

In a bundle G, Jensen's inequality for the logarithm, in the proportions σ'_l/g, gives $\sum_G \sigma'_l \log(\sigma'_l e^{-y_l}) \geq -g\log\left(g^{-1}\sum_G e^{y_l}\right)$, with equality exactly when e^{y_l}/σ'_l is constant on G. □

Definition 31.10 (Keyhole continuations along a direction; ceiling and phase). As stated, for every piece of 31.4 and the sectors of any fan of its seam word.

Proof. The displayed sum is 31.4(ii) at the sums of the shares over the monomials of the partner. A set Y of a box is compact and is the product of a box, of intervals, and of keyholes, a closed disc about 0 joined to a segment of the positive axis (20.47); each factor is star-shaped, about the centre of its disc for a keyhole, so Y is star-shaped, and so is Y plus a small open polydisc about 0. The sector letters do not vanish on Y, by the definition of a keyhole continuation, hence on such a neighbourhood of Y, which is simply connected, so they have logarithms there. The real points of Y form a product of intervals, connected, containing points with nonnegative coordinates, where the letters, with their nonnegative coefficients and positive constant terms, are positive; real and without zeros on that set, they are positive on it, and the logarithms can be taken real at the real points. For a piece of tables and the sectors of the orders, the walls of the generators are the proper walls of the tails and the sector letters are those of 8.5(ii) (31.4(ii)). □

Theorem 31.11 (The travelling bound past the walls). *As stated, for every piece of 31.4.*

Proof. This is the reference's proof (the reference, proof of thm:keyholebound), with the sectors of the fan in place of the orders of B and the generators in place of the tails.

(i) Fix a sector π, a box Ξ of it, the set J of its falling variables with keyholes and their radii r_k, and choose $r_k^- \in (0, r_k)$ with $\sum_{k\in J}(-\dot\kappa_k)\log(r_k/r_k^-) < \epsilon/2$. The term of π is $|\det(\mathbf{v}_{\pi,1},\dots,\mathbf{v}_{\pi,|B|-1})| \int \prod_{k\in J} q_k^{\kappa_k(\bar{\mathbf{z}})-1}\Phi\, dq$, with $\Phi = \prod_{k\notin J} q_k^{\kappa_k(\bar{\mathbf{z}})-1}\mathbf{k}_\pi(q)^{-\bar{\mathbf{z}}}$ holomorphic in the variables of J on a neighbourhood of their keyholes, because the sector letters do not vanish on the sets Y. The following steps apply as in the reference:

- 20.45, applied in the variables of J one at a time with r_k^- and r_k;
- the maximum modulus principle in the variables of $J \setminus A$ that lie in their discs;
- the exact integration of the falling monomials, which carries no phase;
- the identity $|k^{-z}| = |k|^{-\operatorname{Re} z} e^{\operatorname{Im} z \arg k}$ at the points of the outline;
- the bounds of the letters above and below on the compact outline;
- the integrability of $q_k^{\kappa_k(\bar{\mathbf{c}})-1}$ over the base variables, the walls being positive at $\bar{\mathbf{c}}$;

- $|\kappa_k(\bar{\mathbf{z}}) + l_k| \geq c\,\delta$ for at most $|B| - 1$ factors.

Each of these uses only the sector form of 31.4(ii): walls affine in the shares and positive at $\bar{\mathbf{c}}$, and sector letters polynomial, positive on the closed cube and nonvanishing on the sets Y. The determinant is a constant, and the boxes, the sets A and the sectors are finitely many.

(ii) The integrand of the share side of 31.4(i) at $\mathbf{c} + \tau\boldsymbol{\sigma} + i\boldsymbol{\vartheta}$ is the Gammas and the coefficients times the seam function, which (i) bounds. The steps are those of the reference:

- for a growing share, the exact bound $|\Gamma(x + iy)|e^{\varphi y} \leq \Gamma(x)(\cos\varphi)^{-x}$ for $|\varphi| < \frac{\pi}{2}$, from $\Gamma(z) = e^{i\varphi z}\int_0^\infty u^{z-1}e^{-ue^{i\varphi}}du$, applied with $\varphi = \upsilon_l(q) + \eta\,\operatorname{sign} y$;
- falling and staying shares absorb $e^{\upsilon_l(q)y}$ against $e^{-\pi|y|/2}$, as $|\upsilon_l| \leq \frac{\pi}{2} - \epsilon_0$;
- Stirling's formula with $\sum_l \sigma_l = 0$, the supremum over q being taken after the integration over the directions of the shares.

Together these give the travelling bound at the rate $h_{\boldsymbol{\upsilon}}(\boldsymbol{\sigma})$. Then 31.3 applies: (H0) off the null set; (H1) by 31.4(ii) with any $\theta < \pi/2$ and Stirling's formula; (H2) at times at distance at least τ^{-3} from the crossings. □

Corollary 31.12 (When the phase costs nothing). *As stated, for every piece of 31.4.*

Proof. In (i) the price $-\sum_{\sigma_l>0}\sigma_l \log\cos\upsilon_l$ vanishes. In (ii), $\log|\varrho_{\pi,\bar{\boldsymbol{\sigma}}}| - \sum_{\sigma_l>0}\sigma_l\log\cos\upsilon_l \leq \log H_{\mathcal{O}}$ on the outline, with equality approached where $|\varrho_{\pi,\bar{\boldsymbol{\sigma}}}|$ approaches $H_{\mathcal{O}}$, the price being nonnegative.

With no falling variables, the outline is the union of the real cubes of the sectors, where the sector letters are positive and the phase vanishes. Differentiating the wall of 31.4(ii) gives $\dot{\kappa}_k = -\langle\sum_{j,D}(\bar{\sigma}_{jD}\mathbf{t}_{jD,\pi} + \bar{\sigma}^*_{jD}\mathbf{t}^*_{jD,\pi}), \mathbf{v}_{\pi,k}\rangle$. So on the section $\varrho_{\pi,\bar{\boldsymbol{\sigma}}} = \prod_{j,D}\big(\prod_k q_k^{\langle\mathbf{t}_{jD,\pi},\mathbf{v}_{\pi,k}\rangle}k_{jD,\pi}\big)^{-\bar{\sigma}_{jD}}\big(\prod_k q_k^{\langle\mathbf{t}^*_{jD,\pi},\mathbf{v}_{\pi,k}\rangle}\psi_{jD,\pi}\big)^{-\bar{\sigma}^*_{jD}} = \mathbf{V}_B^{-\bar{\boldsymbol{\sigma}}}$, read in the sector coordinates. The cubes of the sectors cover the section, so the ceiling is $\sup\mathbf{V}_B^{-\bar{\boldsymbol{\sigma}}}$, the monomial being homogeneous of degree zero, and the rate is that of 31.2 for the glue read in the monomials of the partner. □

Proposition 31.13 (How travelling bounds compose). *As stated, the face coefficient of (iii) being read on the sectors of any fan of the seam word.*

Proof. (i) and (ii) are the reference's (the reference, proof of prop:pathcompose). For (iii), the reference's proof applies with one sentence changed: a wall $\kappa_{\mathbf{v}}$ is the exponent of q_k in each sector of which $\mathbf{v} = \mathbf{v}_{\pi,k}$ is a generator (31.4(ii)).

- The pole is simple, as opposed to the multiple poles of the statement, when no other factor and no second wall of a sector is polar on the hyperplane. Then, by 8.4, the residue of the sector integral in the direction $\mathbf{e}$ at $\kappa_{\mathbf{v}} = -n$ is $|\det(\mathbf{v}_{\pi,1},\dots,\mathbf{v}_{\pi,|B|-1})|$ times the integral over the other coordinates of the n-th Taylor coefficient in q_k of the rest of the integrand, divided by $\partial_{\mathbf{e}}\kappa_{\mathbf{v}}$. Summing over the sectors gives the face coefficient.
- The other powers $q_{k'}^{\kappa_{k'}-1}$ do not depend on q_k, so the Taylor coefficient is that of the product of the powers of the sector letters: a finite sum of products of derivatives of the letters and powers of the letters at $q_k = 0$, with coefficients polynomial in the exponents.
- Where two walls of one sector lie in $-\mathbb{N}$ on the hyperplane, the expansion of 8.4 in both variables gives a pole of the second order. A Laurent coefficient of a product is a finite sum of products of Laurent coefficients, and the derivatives in the shares of $q^{\kappa(\mathbf{z})}$ and of k^{-z} bring $\log q$ and $-\log k$.

- The wall crossed falls along the direction, so q_k is a falling variable and $q_k = 0$ lies in its keyhole, where the letters do not vanish; Cauchy's estimate on $|q_k| = r_k$ bounds the n-th Taylor coefficient by r_k^{-n} times the largest modulus on the circle.

□

Definition 31.16 (A rational retained cohort). As stated: the fibre integrals of Gammas, coefficients and source factors whose pins carry a grading.

Proof. The share side of 31.4(i) and the kernel of 31.7 are graded by their letter totals: the sum of the rows of the pins that fix the totals of the letters takes the value 1 on the column of every share, each share belonging to one letter. By 31.4(ii), the sector integrals of a fan of a seam word are cube integrals $\int_{[0,1]^k} q^{\boldsymbol{\kappa}(\mathbf{a})-\mathbf{1}} \prod_i P_i(q)^{-w_i(\mathbf{a})} dq$. Here the P_i are the sector letters, with nonnegative coefficients and positive constant terms, and the κ_i and w_i are affine with rational linear parts; for tables these are the sector integrals of 8.6. □

Remark. The grading is part of the definition because 31.18 extracts the scalar of a joint word through the change of logarithmic scales $z = \rho\mathbf{v} + E\log X$, which needs a vector $\mathbf{v}$ taking the value 1 on every column. Without one the form of that theorem can fail, as follows.

Take the Gramma $\mathsf{G}_{\nu;(1,2)}(\xi_1,\xi_2) = \int_0^\infty x^{\nu-1} e^{-\xi_1 x - \xi_2 x^2} dx$, $\nu, \xi_1, \xi_2 > 0$. Its configuration has no grading, since $\langle 1, v\rangle = \langle 2, v\rangle = 1$ is impossible. Its share side is pinned by $b_1 + 2b_2 = \nu$, and its closing along $(-2, 1)$ crosses $b_1 = -N$, $N \in \mathbb{N}$, with the crossing terms

$$\frac{(-\xi_1)^N}{N!} \cdot \frac{1}{2}\Gamma\Big(\frac{\nu+N}{2}\Big)\xi_2^{-(\nu+N)/2},$$

the terms of the expansion of the integral in powers of ξ_1, using $\int_0^\infty x^{\nu+N-1} e^{-\xi_2 x^2} dx = \frac{1}{2}\Gamma(\frac{\nu+N}{2})\xi_2^{-(\nu+N)/2}$.

The scalar $\Gamma(\frac{\nu+N}{2})/\Gamma(N+1)$ has an N-th root tending to 0: its logarithm divided by N is $-\frac{1}{2}\log N + O(1)$. A joint word with the scalar of 31.18, here with $r_G = 1$, would in this positive case have the root rate $\operatorname{ess\,sup} c > 0$, or vanishing terms (31.19).

Theorem 31.18 (A finite procedure for a retained cohort). *As stated, for every retained cohort, the scalar being written through the grading of its pins.*

Proof. This is the reference's proof (the reference, proof of thm:retainedchain); only the radial step involves the totals of the shares.

- At a Gamma crossing, the crossed share is fixed at $-N(n)$, and its Gamma is replaced by the residue $(-1)^{N(n)}/\Gamma(N(n)+1)$.
- The crossed share and its added pin are eliminated together. This leaves the columns t_l, $l \neq f$, of the original pins, with the values $\boldsymbol{\nu} + N(n)t_f$, t_f the column of the crossed share.
- By 31.14 each share of $\mathcal{S}_-$ is translated, $b_l = a_l + \delta_l(n)$, with the factor $(-1)^{\delta_l(n)}\xi_l^{\delta_l(n)}/\Gamma(\delta_l(n))$, the power of ξ_l staying in the joint input.

The completed retained fibre is then the Gramma $\mathsf{G}_{\boldsymbol{\mu}_n;t}$ (4.2), with the remaining columns and the index $\boldsymbol{\mu}_n = \boldsymbol{\nu} + N(n)t_f + \sum_{l\in\mathcal{S}_-} \delta_l(n) t_l$. Every remaining column is a column of the original pins, so $\langle t_l, \mathbf{v}\rangle = 1$ for the grading $\mathbf{v}$, and

$$S_n = \langle \mathbf{v}, \boldsymbol{\mu}_n\rangle = w + N(n) + \sum_{l\in\mathcal{S}_-} \delta_l(n).$$

The change of logarithmic scales $z = \rho\mathbf{v} + E\log X$, with E a rational matrix whose columns complement $\mathbf{v}$, gives $\mathsf{G}_{\boldsymbol{\mu}_n;t} = J_{\mathbf{v}}\Gamma(S_n)\int X^{E^{\mathsf{T}}\boldsymbol{\mu}_n{}^{-\mathbf{1}}}\mathcal{L}(X)^{-S_n}dX$: the integral over ρ is $\Gamma(S_n)\mathcal{L}^{-S_n}$. Collecting the residue, the factors of the translations and $\Gamma(S_n)$ gives the stated G_n. Its slopes in n agree in the numerator and the denominator, $d_0 + \sum_{\mathcal{S}_-} d_l = \bar{d}$, so the terms $n\log n$ of Stirling's formula cancel, and the rest of Stirling's formula gives r_G and the polynomial bound. On the share sides of 31.4 and 31.7, $\mathbf{v}$ is the sum of the letter-total rows and $w = |\mathbf{s}| + |\mathbf{t}|$. The other steps of the procedure (the source strips, the circles, the joint read, the resolution of the endpoints and the fan) do not involve the grading. □

Theorem 31.26 (The exact positive rate of a retained chamber). *As stated, with a real index.*

Proof. The reference's proof (the reference, proof of thm:retainedchamberrate) uses rationality only of the configuration and of the direction, through the cohort and its integer step.

- 31.16 allows real constant terms and indices. The crossing times of a falling share are $(a_l^0 + N)/d_l$, $N \in \mathbb{N}$, and passing to the integer step makes the changes of all falling shares integral, whatever the constant terms.
- The positive construction uses 31.14 with $\delta_l(n) = \delta_l(0) + d_l n$ and real starting values.
- The rate is computed by 31.25, at the slope $\sum_f d_f t_f$ of the index, which does not involve its constant term.
- The root limit is that of 31.19, whose positive case allows real constant terms.

The chamber polytope of the statement is the chamber of 31.5 of the share side, whose polar functions are the shares (31.5), for the direction per step. □

Theorem 31.28 (Averaging is sharp). *As stated, for every share side of Theorem 31.7 and every direction with rational coordinates whose crossings are simple and nonresonant.*

Proof. At each source point the kernel of 31.7(i) is, up to the constant factor $\prod_j \Gamma(s_j)^{-1}\prod_j \Gamma(t_j)^{-1}$, the share side of the Gramma whose configuration is the matrix of the pins, rational by hypothesis, with the grading of the letter totals; whose index is the vector of the values of the pins, real; and whose coefficients are $e^{y_l(\zeta)}$, positive and continuous in ζ (4.2). Let $\boldsymbol{\sigma}$ be rational and the crossings of its ray simple and nonresonant. A falling share l crosses its poles at the times $(c_l + N)/|\sigma_l|$, $N \in \mathbb{N}$; for a rational $\Delta > 0$ with every $\Delta\sigma_l$ an integer these times fall into finitely many progressions of step Δ, so the crossing terms form finitely many cohorts with the integer step of length Δ in τ (31.16), the direction per step being $\Delta\boldsymbol{\sigma}$, from the positive point $\mathbf{c}$.

- 31.26, with a real index, gives every retained term a sign at each index that does not depend on the coefficients, hence not on ζ, so the averaged term has that sign.
- 31.27 applies to each cohort: one averaged term is absolutely integrable by 31.7(i) and its certificate, $\hat{h}_C < \infty$, and the coefficient map is continuous, so the essential supremum of the chamber rate is its supremum on S_λ.
- The chamber of the step direction is ΔC, and since $\sum_l \sigma_l' = 0$ on V, $h(\Delta\boldsymbol{\sigma}'; y) = \Delta h(\boldsymbol{\sigma}'; y)$. So the root rate per step is the limit $e^{\Delta\hat{h}_C}$.

Hence for every $\epsilon > 0$ and every cohort, $|\int \mathcal{R}_n\, d\lambda| \geq e^{n\Delta(\hat{h}_C - \epsilon/2)}$ for all large n. The crossing time being $\tau_n = \tau_0 + n\Delta$, this exceeds $e^{\tau_n(\hat{h}_C - \epsilon)}$ for all large n, the quotient being $e^{n\Delta\epsilon/2 - \tau_0(\hat{h}_C - \epsilon)}$; the cohorts being finitely many, the bound holds for all large k. With 31.7(ii), the terms tend to zero when $\hat{h}_C < 0$ and do not when $\hat{h}_C > 0$.

Now let every falling share be alone in its bundle and the merged fibre have dimension one.

- The merged pins are rational, so the merged directions form a line spanned by a rational vector $\mathbf{r}$. The merged direction of $\boldsymbol{\sigma}$, nonzero since $\boldsymbol{\sigma}$ falls a share, which is alone in its bundle, is $\mu\mathbf{r}$ with $\mu \neq 0$, and $\mu > 0$ after the choice of the sign of $\mathbf{r}$. The falling coordinates of the positive multiple $\mu^{-1}\boldsymbol{\sigma}$ of $\boldsymbol{\sigma}$ are coordinates of $\mathbf{r}$, rational.
- The chamber of $\mu^{-1}\boldsymbol{\sigma}$ is a nonempty polytope defined by rational equations and inequalities, so its vertices have rational coordinates. By 31.6 the closing along $\mu^{-1}\boldsymbol{\sigma}$, which is the closing along $\boldsymbol{\sigma}$ after a change of scale of τ, is the closing along that rational direction.
- At a crossing time the growing shares are positive at the real point of the ray, so the crossing is simple and nonresonant exactly when no other falling share lies in $-\mathbb{N}$ there, that is, when no two lattices of the falling shares meet.

The form of the crossing terms is the reference's (the reference, proof of thm:pool(iv)). The fibre is a bundle over the merged line whose fibres are the splits of the bundles at fixed sums, and 4.4 completes each split, $\int_{\sum_{l\in G} a_l=\bar{a}} \prod_{l\in G} \Gamma(a_l) e^{-a_l y_l} = \Gamma(\bar{a}) e^{-\bar{a} y_G}$. A crossing term on the merged line is a fibre integral of dimension zero: the residue of the Gamma crossed, times the other Gammas at the crossing point and $\prod_G e^{-\bar{a}_{k,G} y_G}$, divided by the Gammas of the exponents and by the determinant of the pins. □

50.32 Chapter 32: laws at their ends: regions of equality and reach

Theorem 32.10 (The reach along a direction is read on the law). *Parts (i) to (iv) as stated, with part (v).*

Proof. Parts (i) to (iv) are the reference's (the reference, proof of thm:dirreach); the piece of tables named in (iii) has a seam word with a Newton sum of full dimension when its tables form a connected family, by 31.4(ii). For (v) fix $\theta \geq 0$ and let g_θ be the infimum of (v).

First, $r \leq g_\theta$. On the half-strip Σ of 32.9 the imaginary parts are bounded, say by Y, so $e^{\theta|\operatorname{Im} z|} \leq e^{\theta Y}$ there. A bound $|\ell(z)| \leq C(1+|z|)^{n'} M^{\operatorname{Re} z} e^{\theta|\operatorname{Im} z|}$ on the half-plane, off the δ-neighbourhoods of the candidate poles, therefore gives on Σ the bound of 32.9 with $Ce^{\theta Y}$, and $r \leq M$.

Second, $g_\theta \leq r$. By (i), on (r,∞) the measure λ has a density that is a wall series of radius r. By (ii) with $x_0 = r$, for every $x' > r$ there is C with $|\ell(z)| \leq C\delta^{-J-1} x'^{\operatorname{Re} z}$ at every z with $\operatorname{Re} z \geq 0$ at distance at least $\delta \leq 1$ from the poles, whatever $\operatorname{Im} z$. The poles with $\operatorname{Re} z \geq 0$ lie among the candidate poles, and those with $\operatorname{Re} z < 0$ keep a distance at least some $\epsilon_0 > 0$ from the half-plane, ℓ converging absolutely on a strip about the imaginary axis (32.9). So at every z with $\operatorname{Re} z \geq 0$ at distance at least δ from the candidate poles, with $\delta_1 = \min(\delta, 1, \epsilon_0)$, $|\ell(z)| \leq C\delta_1^{-J-1} x'^{\operatorname{Re} z}$: the bound of (v) with the constant $C\delta_1^{-J-1}$ and $n' = 0$. So $M = x'$ is admissible in (v) at $\theta = 0$, hence at every $\theta \geq 0$, the factor $e^{\theta|\operatorname{Im} z|}$ being at least 1, and $g_\theta \leq x'$ for every $x' > r$. □

Theorem 32.15 (Ceilings, simple tops and fibres along a direction). *As stated, for every piece whose seam function converges at a real point of the pins with positive shares, with the sectors of any fan of its seam word.*

Proof. By 31.4(ii) the piece has walls and growth bounds (32.7), its walls being those of the generators of the fan, so 32.9 applies with these walls. The proof is the reference's (the reference,

proof of thm:dirheights), with the sectors of the fan in place of the orders of B, the generators in place of the tails, and the constant $|\det(\mathbf{v}_{\pi,1},\dots,\mathbf{v}_{\pi,|B|-1})|$ in the sector forms. At the point $\mathbf{w}_0 + i\bar{\boldsymbol{\vartheta}} + z\bar{\boldsymbol{\sigma}}$ the integrand of the sector integral of π is

$$|\det(\mathbf{v}_{\pi,1},\dots,\mathbf{v}_{\pi,|B|-1})| \prod_k q_k^{\kappa_k(\mathbf{w}_0)+i\partial_{\bar{\boldsymbol{\vartheta}}}\kappa_k-1}\, \mathbf{k}_\pi^{-\mathbf{w}_0-i\bar{\boldsymbol{\vartheta}}}\, \varrho_{\pi,\bar{\boldsymbol{\sigma}}}^{z}.$$

(i) The proof of 31.11(i) concerns the seam function alone. It holds at the points $\mathbf{w}_0 + \operatorname{Re} z\,\bar{\boldsymbol{\sigma}} + i(\bar{\boldsymbol{\vartheta}} + \operatorname{Im} z\,\bar{\boldsymbol{\sigma}})$, with δ the distance of the complex point from the hyperplanes on which a wall lies in $-\mathbb{N}$, which is at least a constant times the distance of z from the candidate poles (the reference, proof of cor:dirtube). On Σ the phase is bounded, the imaginary parts being bounded there. So $|\ell(z)| \le C\delta^{-(|B|-1)} e^{\operatorname{Re} z(\log H_{\mathcal{O}}+\epsilon)}$, and $r \le H_{\mathcal{O}} e^{\epsilon}$ for every $\epsilon > 0$.

(ii) and (iii) follow from the proof of 20.51(i) and (iii), with the point $\mathbf{w}_0 + m\bar{\boldsymbol{\sigma}}$ in place of $b^d = -k$, $\varrho_{\pi,\bar{\boldsymbol{\sigma}}}$ in place of ϱ_π and $\phi_{\pi,\mathbf{w}_0}$ in place of ϕ_π.

- The falling variables carry $q_k^{\kappa_k(\mathbf{w}_0)-m|\dot{\kappa}_k|-1}$ with $|\dot{\kappa}_k|$ an integer, so the factor $(e^{2\pi i\kappa_k(\mathbf{w}_0)}-1)^{-1}$ of their circles is the same at every m. The letters whose exponents are nonnegative integers at every large m carry polynomials and need not be kept from vanishing.
- Every wall is the wall of a generator of some sector, so its falling rate is one of the integers $|\dot{\kappa}_k|$. The points m lie at a distance bounded below from the candidate poles, the falling walls being off the integers at $\mathbf{w}_0$, so $|\ell(m)| \le C(1+m)^D r'^m$ for every $r' > r$ by 32.9, and $\operatorname{growth}_{\mathbb{Z}} \le r$.
- Under (iii), $\operatorname{growth}_{\mathbb{Z}} = H_{\mathcal{O}}$ as in 20.51(iii), and a keyhole continuation of ceiling $H_{\mathcal{O}}$ gives $r \le H_{\mathcal{O}}$ by (i).

(iv) follows from the proofs of 20.55 and 20.56, applied to the positive directional law, with 32.10(i) and (ii) in place of 20.44.

- A keyhole box is handled as in (i).
- In a fibre box, $\varrho_{\pi,\bar{\boldsymbol{\sigma}}}$ is meromorphic in each falling variable on its disc, the exponents $\bar{\sigma}_L$ and $\dot{\kappa}_j$ being integers. At a point above the ceiling and the stationary bound, the map is a submersion on its stratum: by 20.52 when one coordinate of falling rate one lies inside its disc, and by the definition of the stationary bound otherwise.
- The Mellin transform of a fibre law is a cube integral as in 20.32, with its poles in finitely many cosets of $(\operatorname{lcm}_j |\dot{\kappa}_j|)^{-1}\mathbb{Z}$, so 20.53 applies.

None of these steps uses more of a sector integral than the form displayed above, which 31.4(ii) supplies for every fan of the seam word of every such piece. □

Theorem 32.16 (The closing past the walls is read along its direction). *As stated, with the last sentence of (i), for the share side of 31.4(iv).*

Proof. Apart from the last sentence of (i), the statement is the reference's (the reference, proof of thm:dirclosing). For that sentence, the piece and the partner have walls and growth bounds (31.4(ii), applied to each), and $\boldsymbol{\sigma}$ has rational coordinates, so 32.12 applies to each of the two seam functions at $\mathbf{c}$, over the whole space V of the directions of the shares. There the growth $g_X(\boldsymbol{\sigma};\theta)$ of 31.4(iv), $X \in \{B,R\}$, is the function $g_V(\boldsymbol{\sigma};\theta)$ of 32.12 for that seam function: the two definitions coincide, the shares carrying no sums and the walls of 31.4(ii) serving as the walls of (W1), so that δ is measured from the same hyperplanes, those of the polar functions of the seam function (31.5).

It does not increase with θ and tends to $r_X^\sharp$ as $\theta \downarrow 0$, so $g_X(\boldsymbol{\sigma};\theta) \le r_X^\sharp$ for every $\theta > 0$. Then

$$h_{\theta/2,\theta/2}(\boldsymbol{\sigma}) \le \sum_l \sigma_l \log|\sigma_l| + \log r_B^\sharp + \log r_R^\sharp + \frac{2\theta^2}{\pi} \sum_{l:\,\sigma_l>0} \sigma_l,$$

which is negative for θ small when $\sum_l \sigma_l \log|\sigma_l| + \log r_B^\sharp + \log r_R^\sharp < 0$. 31.4(iv) gives the closing, its terms and remainders being $O(e^{\tau(h_{\theta/2,\theta/2}(\boldsymbol{\sigma})+\epsilon)})$, and letting $\theta \to 0$ gives the stated bound. □

Corollary 32.18 (A law with log expansions bounds a closing of any fibre dimension). *As stated, with its last sentence, for the share side of 31.4(iv).*

Proof. Apart from the last sentence, the statement is the reference's (the reference, proof of cor:anyfibre). For that sentence, apply 32.14 to the law of the piece and to that of the partner, a piece with the reversed excesses. On the contour through $\mathbf{c} + \tau\boldsymbol{\sigma}'$ each seam function is at most $C\delta^{-n} X_{\text{in}}^X(\boldsymbol{\sigma}')^\tau$, with no factor in the imaginary parts and no power of τ, so $g_X(\boldsymbol{\sigma}';0) \le X_{\text{in}}^X(\boldsymbol{\sigma}')$ for every direction $\boldsymbol{\sigma}'$. Hence

$$h_{0,0}(\boldsymbol{\sigma}') \le \sum_l \sigma_l' \log|\sigma_l'| + \log X_{\text{in}}^B(\boldsymbol{\sigma}') + \log X_{\text{in}}^R(\boldsymbol{\sigma}'), \qquad \boldsymbol{\sigma}' \in C(\boldsymbol{\sigma}).$$

The polar functions of the share side of 31.4(iv) are the shares and the walls of both words, with $\Omega = A$, and (H1) holds by 31.4(ii) and Stirling's formula. So 31.6 makes the closings along the directions of the chamber one series; their crossings and the near coincidences of these are those of the falling polar functions, the same for every direction of the chamber, so $\mathbf{c}$ lies off the null set of 31.4(iv) for each of them; and 31.4(iv) at $\theta_B = \theta_R = 0$, along a direction of the chamber whose bound is within ϵ of the infimum, gives the closing along $\boldsymbol{\sigma}$ with the stated bound. On the chamber the falling coordinates are fixed and the others are nonnegative, where $x \log x$ is convex, and the logarithms of the inner bounds are convex (32.13). □

Remark (The directional ratio at width one, in the paragraph after 32.9). At width one with one table, factoring weights normalized as in 28.11, and $s, t > 0$, the directional ratio $x_{D_0}^*/x_{D_1}$ along $\bar{\boldsymbol{\sigma}} = (-1, 1, -1, 1)$ is the ratio ϱ_B at the seam points, and every coordinate of the seam torus there is a power of ϱ_B.

Proof. On the seam torus $x_{D_0} = x_{D_1}^* = 1$, so $\mathbf{x}^{-\bar{\boldsymbol{\sigma}}} = x_{D_0}\, x_{D_1}^{-1}\, x_{D_0}^*\, x_{D_1}^{*-1} = x_{D_0}^*/x_{D_1}$. At the seam point of u, 28.5 gives $\varrho_{D_0}^{\rho*}/\varrho_{D_1}^{\rho} = V_{D_0}^* V_{D_0}/(V_{D_1}^* V_{D_1})$, the scale cancelling. By Lemma S13(i) this is

$$\Big(\frac{\hat\theta_0}{\hat\theta_1}\Big)^2 \frac{\Psi_{\mathcal{B}/R}\, K_{\mathcal{B}/R}}{\Psi_{\mathcal{B}|B}\, K_{\mathcal{B}|B}} = \Big(\frac{\hat\theta_0}{\hat\theta_1}\Big)^2 \varrho_B,$$

with $\varrho_B = \gamma_B^\Psi/\gamma_B^K$ of 19.2. Under the normalization $\hat\theta_0 = \hat\theta_1 = 1$, so it is ϱ_B. By 28.11(ii) with $N = 1$, $\mathbf{x} = (1, \varrho_B)$ and $\psi = \varrho_B^{t/(s+t)}$, the coordinates of the seam point are 1, $\varrho_B^{-t/(s+t)}$, $\varrho_B^{s/(s+t)}$ and 1, all powers of ϱ_B. □

50.33 Chapter 34: the motive of a family and the coaction along a tree

Five outside works enter these proofs, each named where it is used together with the property of the setting it needs: the theory of toric varieties (W. Fulton, *Introduction to toric varieties*, Princeton

University Press, 1993, Chapters 1 to 3), for the braid fan; F. Brown, *Notes on motivic periods*, Commun. Number Theory Phys. 11 (2017), 557–655 (*Brown's notes*), for motivic periods, the coaction and the weight-graded face maps; F. Brown, *Feynman amplitudes, coaction principle, and cosmic Galois group*, Commun. Number Theory Phys. 11 (2017), 453–556, §5, for the affine model; A. Huber and S. Müller-Stach, *Periods and Nori motives*, Springer, 2017, for the functoriality of relative cohomology in Nori's category, whose objects and morphisms realize in Brown's category; and H. Hironaka, *Resolution of singularities of an algebraic variety over a field of characteristic zero*, Ann. of Math. 79 (1964), 109–326. In this section a *pair* (V, D) is a smooth variety V over $\mathbb{Q}$ of dimension m with a divisor $D \subset V$ with simple normal crossings and smooth components. Its relative cohomology $H^m(V, D)$ is an object of Brown's category, a morphism of pairs giving a morphism of Nori's category and so of Brown's (Huber and Müller-Stach). A regular form η of degree m on V is closed and restricts to zero on the components of D, which have smaller dimension; $[\eta]$ is its class in $H^m_{\mathrm{dR}}(V, D)$. A compact semialgebraic $\sigma \subset V(\mathbb{R})$ that is the closure of an oriented open semialgebraic set $\sigma^\circ \subseteq (V \setminus D)(\mathbb{R})$ of dimension m, with $\sigma \setminus \sigma^\circ \subseteq D$, is a *relative cycle*: a semialgebraic triangulation makes the sum of its oriented top simplices a chain whose boundary lies in $D(\mathbb{R})$, and its class in $H_m(V(\mathbb{C}), D(\mathbb{C}); \mathbb{Q})$ is written σ again. The comparison of the two realizations is integration, so the period of $[H^m(V, D), \sigma, [\eta]]^{\mathrm{mot}}$ is $\int_\sigma \eta$. The positive cells $\widetilde{\sigma}_Z$ are oriented as in Definition 34.5.

Definition 34.1 (The model of a family). As stated.

Proof. $\Omega_{\mathcal{E}}$ is the contraction of $d\alpha_{e_1} \wedge \cdots \wedge d\alpha_{e_n}$ with the vector field $\sum_e \alpha_e \, \partial/\partial\alpha_e$, which does not depend on the order, while the volume form changes by the sign of the permutation. The coefficient $f = \alpha^{\mathbf{m-1}} \prod_j K_j^{-s_j} \Psi_j^{-t_j}$ of $\omega_F = f\,\Omega_{\mathcal{E}}$ is homogeneous of the degree $m_{\mathcal{E}} - \sum_j (s_j r_j + t_j r_j^*) - n = \kappa_{\mathcal{E}} - n = -n$ (Definition 8.1), the masses being on the balance wall. With the affine coordinates $x_i = \alpha_{e_i}/\alpha_{e_n}$, $i < n$, of the chart $\alpha_{e_n} \neq 0$ of $\mathbb{P}(\mathbb{Q}^{\mathcal{E}})$, a direct computation gives $dx_1 \wedge \cdots \wedge dx_{n-1} = (-1)^{n-1} \alpha_{e_n}^{-n} \Omega_{\mathcal{E}}$, so that $f\,\Omega_{\mathcal{E}} = (-1)^{n-1} f(x_1, \ldots, x_{n-1}, 1)\, dx_1 \wedge \cdots \wedge dx_{n-1}$ is the pull-back of a rational form on that chart. These forms agree on the overlaps of the charts, all pulling back to $f\,\Omega_{\mathcal{E}}$ on $\mathbb{Q}^{\mathcal{E}} \setminus \{0\}$; so ω_F is a rational form of degree $n-1$ on $\mathbb{P}(\mathbb{Q}^{\mathcal{E}})$, and on $X_{\mathcal{E}}$, which contains the torus of $\mathbb{P}(\mathbb{Q}^{\mathcal{E}})$ as a dense open set. □

Definition 34.2 (Flags and steps). As stated.

Proof. The steps are $\ell + 1$ nonempty sets that partition $\mathcal{E}$, so $\sum_i (|Z_i| - 1) = n - 1 - \ell$. For $\ell \geq 1$ the step lists at Z_i depend on S_{i-1} and S_i alone (Proposition 12.20), and the α_J with $J \subseteq Z_i$ on Z_i alone; so does $\mathrm{Let}(Z_i; \mathfrak{f})$. When $|Z_i| = 1$, X_{Z_i} is the toric variety of the fan $\{0\}$ in $\mathbb{R}^{Z_i}/\mathbb{R}\mathbf{1} = 0$, a point, and the step has no letter: the basis polynomials of the lists on one mark are 1 and α_e, monomials, and no $J \subseteq Z_i$ has two marks. □

Lemma 34.3 (Charts, strata and the letters in a chart). *As stated.*

Proof. (i) The fan lies in $N_{\mathbb{R}}$, $N = \mathbb{Z}^{\mathcal{E}}/\mathbb{Z}\mathbf{1}$, with the dual lattice $M = \{\mathbf{a} \in \mathbb{Z}^{\mathcal{E}} : \; a_{\mathcal{E}} = 0\}$, whose elements are the characters $\alpha^{\mathbf{a}}$ of the torus. For an order $e_1, \ldots, e_n$ the vectors $\mathbf{1}_{S_1}, \ldots, \mathbf{1}_{S_{n-1}}, \mathbf{1}$ form a basis of $\mathbb{Z}^{\mathcal{E}}$, their matrix in the basis $(\mathbf{e}_{e_k})_k$ being triangular with ones on the diagonal; so the images of $\mathbf{1}_{S_1}, \ldots, \mathbf{1}_{S_{n-1}}$ form a basis of N, with the dual basis $\mathbf{e}_{e_i} - \mathbf{e}_{e_{i+1}}$, $i < n$, of M, since $\langle \mathbf{1}_{S_k}, \mathbf{e}_{e_i} - \mathbf{e}_{e_{i+1}} \rangle$ is 1 for $k = i$ and 0 otherwise. Every $\mathbf{x} \in \mathbb{R}^{\mathcal{E}}$ lies in such a cone modulo $\mathbf{1}$: ordering $\mathcal{E}$ with $x_{e_1} \geq \cdots \geq x_{e_n}$, $\mathbf{x} = \sum_{i<n} (x_{e_i} - x_{e_{i+1}}) \mathbf{1}_{S_i} + x_{e_n} \mathbf{1}$. The cones of two chains meet in the cone of their common sets, a face of both. So the braid fan is a complete fan whose cones are spanned by parts of bases of N; it is the normal fan of the polytope $\sum_{\{a,b\}} \mathrm{conv}\{\mathbf{e}_a, \mathbf{e}_b\}$, the sum over the pairs of marks, since on the interior of the cone of an order a linear form $\mathbf{x}$ has

$x_{e_1} > \cdots > x_{e_n}$ and attains its least value on that polytope at the one vertex $\sum_{\{a,b\}} \mathbf{e}_{\max(a,b)}$, the maximum taken in the order, which is the same on the whole cone and differs for different orders. By the dictionary between fans and toric varieties (Fulton, Chapters 1 to 3), which applies to such a fan, $X_{\mathcal{E}}$ is smooth and complete, and projective, the fan being a normal fan; the chart of the cone of the chain is the affine space with the coordinates $\alpha^{\mathbf{e}_{e_i}-\mathbf{e}_{e_{i+1}}} = \varepsilon_i$; the charts of the maximal cones cover $X_{\mathcal{E}}$; and the closure D_S of the orbit of the ray ρ_S meets the chart exactly when ρ_S is a ray of its cone, in the coordinate hyperplane of the dual coordinate, here $\{\varepsilon_i = 0\}$ for $S = S_i$, several of these closures meeting exactly when their rays span a cone, here when their sets form a chain (the orbit–cone correspondence). In every chart D is a union of coordinate hyperplanes, so it has simple normal crossings and smooth components. In every chart the torus is $\{\varepsilon_i \neq 0 \text{ for all } i\}$ and $\widetilde{\sigma}^\circ_{\mathcal{E}} = (0,\infty)^{n-1}$, since $\alpha_{e_j}/\alpha_{e_n} = \prod_{i\geq j} \varepsilon_i$; its closure in the open set $U(\mathbb{R})$ is $[0,\infty)^{n-1} = \widetilde{\sigma}_{\mathcal{E}} \cap U$. The points of $\widetilde{\sigma}^\circ_{\mathcal{E}}$ with $\alpha_{e_1} < \cdots < \alpha_{e_n}$ are $(0,1)^{n-1}$ in the chart, with the closure $[0,1]^{n-1}$, compact and so closed in $X_{\mathcal{E}}(\mathbb{R})$. Every point of $\widetilde{\sigma}^\circ_{\mathcal{E}}$ is a limit of points with distinct coordinates, so $\widetilde{\sigma}^\circ_{\mathcal{E}}$ lies in the union of the sectors, a finite union of compact sets, and so does its closure $\widetilde{\sigma}_{\mathcal{E}}$, which contains every sector. The open cube $(0,1)^{n-1}$ of one order is open in $X_{\mathcal{E}}(\mathbb{R})$ and misses the open sector of every other order, hence its closure; so two sectors meet in the boundary of a cube, of measure zero.

(ii) For a basis T of a table of rank δ, $\alpha^T/\alpha^\delta_{e_n} = \alpha^{\mathbf{1}_T - \delta\mathbf{e}_{e_n}} = \prod_{i<n} \varepsilon_i^{|T\cap S_i|}$, by the dual basis of (i) and $e_n \notin S_i$. So $K_{\mathcal{B}}/\alpha^\delta_{e_n}$ is the sum of these monomials over the bases. Every exponent $|T \cap S_i|$ is at least $d(S_i)$ (Theorem 7.13), and along the maximal chain $(S_i)_{i<n}$ exactly one basis has $|T \cap S_i| = d(S_i)$ for every i, its term having the coefficient 1 (Proposition 12.20); dividing by its monomial leaves $\widetilde{f}$, a polynomial with nonnegative integer coefficients, the numbers of bases with given traces, and with the constant term 1. For $\Psi_{\mathcal{B}} = K_{\mathcal{B}^*}$ the same holds with the dual table, whose floors are the $d^*(S)$ (Proposition 7.2, Theorem 7.13), and for α_J with the list $\binom{J}{1}$ on $\mathcal{E}$, whose floor at S is 1 or 0 as $J \subseteq S$ or not. In the sector coordinates of Theorem 8.5(ii), with $\pi(k) = e_{n+1-k}$, the coordinates are $q_k = \varepsilon_{n+1-k}$ and the tails are $U_k = S_{n+1-k}$, and $\widetilde{f}$ is the sector letter there. On $\varepsilon \geq 0$, $\widetilde{f} \geq 1$.

On $\{\varepsilon_i = 0 :\ i \in I\}$ only the bases T with $|T \cap S_i| = d(S_i)$ for every $i \in I$ leave a term. By Proposition 12.20 for the chain $(S_i)_{i\in I}$ they are the unions $\bigsqcup_Z X_Z$ of one basis X_Z of the step table at the bottom at each step Z of that chain. For $i \notin I$ let $Z = S_b \setminus S_a$ be the step with $S_a \subsetneq S_i \subsetneq S_b$, where S_a may be $\varnothing$ and S_b may be $\mathcal{E}$; then $|T \cap S_i| = d(S_a) + |X_Z \cap (S_i \setminus S_a)|$. The basis at the bottom of the maximal chain is one of these unions and has the least traces, so $d(S_i) - d(S_a)$ is the floor $d_Z(S_i \setminus S_a)$ of $S_i \setminus S_a$ in the step table at Z, and

$$\widetilde{f}\big|_{\{\varepsilon_i = 0:\, i\in I\}} = \prod_Z \sum_{X_Z} \prod_{a<k<b} \varepsilon_k^{|X_Z \cap (S_k \setminus S_a)| - d_Z(S_k \setminus S_a)}.$$

The factor of Z is the polynomial that the rule above attaches to K of the step table in the chart of X_Z of the order $e_{a+1}, \ldots, e_b$, whose initial segments are the $S_k \setminus S_a$ and whose coordinates are the ε_k, $a < k < b$. For Ψ the same holds with the tops and the dual tables, and for α_J with its step letters (Proposition 12.20). Finally, on the torus part of U, $f = 0$ exactly where $\widetilde{f} = 0$. No irreducible component of $\{\widetilde{f} = 0\}$ lies in a coordinate hyperplane $\{\varepsilon_i = 0\}$, since ε_i does not divide $\widetilde{f}$, whose constant term is 1; so each component is the closure of its part in the torus, and $\{\widetilde{f} = 0\}$ is the closure in U of the zero set of f in the torus, that is $\widetilde{Y}_f \cap U$.

(iii) In the affine coordinates $x_j = \alpha_{e_j}/\alpha_{e_n} = \prod_{i\geq j} \varepsilon_i$, $\Omega_{\mathcal{E}}/\alpha^{\mathcal{E}} = (-1)^{n-1} \bigwedge_{j<n} dx_j/x_j$ (proof of Definition 34.1), and $\bigwedge_j d\log x_j = \bigwedge_i d\log \varepsilon_i$, the matrix of the $\log x_j$ in the $\log \varepsilon_i$ being triangular with ones on the diagonal; so $\Omega_{\mathcal{E}}/\alpha^{\mathcal{E}} = (-1)^{n-1} \bigwedge_{i<n} d\varepsilon_i/\varepsilon_i$. By (ii), $\alpha^{\mathbf{m}}/\alpha^{m_{\mathcal{E}}}_{e_n} = \prod_i \varepsilon_i^{m_{S_i}}$, $K_j/\alpha^{r_j}_{e_n} = \prod_i \varepsilon_i^{d_j(S_i)} \widetilde{K}_j$ and $\Psi_j/\alpha^{r^*_j}_{e_n} = \prod_i \varepsilon_i^{d^*_j(S_i)} \widetilde{\Psi}_j$. On the balance wall the powers of α_{e_n} cancel,

and the exponent of ε_i is $m_{S_i} - \sum_j \big(s_j d_j(S_i) + t_j d_j^*(S_i)\big) - 1 = \kappa_{S_i} - 1$. □

Lemma S15 (Integrals over the positive cell)**.** *Let ϕ be a measurable function on $\mathbb{R}^{\mathcal{E}}_{>0}$, homogeneous of degree zero, $n = |\mathcal{E}| \geq 2$. Then, in $[0,\infty]$ when $\phi \geq 0$, and whenever one side converges absolutely,*

$$\int_{\widetilde{\sigma}^\circ_{\mathcal{E}}} \phi\, \frac{\Omega_{\mathcal{E}}}{\alpha^{\mathcal{E}}} = \int_{\Delta_{\mathcal{E}}} \phi(u)\, u^{-\mathbf{1}}\, d\omega_{\mathcal{E}}(u) = \int_{\Delta_B \times \Delta_R} \int_0^\infty \phi(\rho u, u')\, \frac{d\rho}{\rho}\; u^{-\mathbf{1}} u'^{-\mathbf{1}}\, d\omega_B(u)\, d\omega_R(u')$$

for every partition $\mathcal{E} = B \sqcup R$ into nonempty sets; in the chart of an order the left side is $\int_{(0,\infty)^{n-1}} \phi \prod_i d\varepsilon_i/\varepsilon_i$. If $\phi\, \Omega_{\mathcal{E}}/\alpha^{\mathcal{E}}$ is the restriction of a form that is regular on an open set containing $\widetilde{\sigma}_{\mathcal{E}}$, the integrals converge absolutely and are its integral over $\widetilde{\sigma}_{\mathcal{E}}$.

Proof. In the logarithmic coordinates $y = \log \alpha$, $\alpha^{-\mathbf{1}} d\alpha = dy$. For an order of $\mathcal{E}$ the linear map $y \mapsto \big((y_{e_i} - y_{e_{i+1}})_{i<n}, y_{e_n}\big)$ has the determinant ± 1, and its first $n-1$ coordinates are the $\log \varepsilon_i$, on which ϕ depends alone. For a positive h homogeneous of degree one and a measurable $\varphi \geq 0$ on $(0,\infty)$, at fixed ε the substitution $\rho = e^{y_{e_n}} h(\alpha/\alpha_{e_n})$ has $d\rho/\rho = dy_{e_n}$; by Tonelli

$$\int_{\mathbb{R}^{\mathcal{E}}_{>0}} \phi(\alpha)\, \varphi\big(h(\alpha)\big)\, \alpha^{-\mathbf{1}} d\alpha = \int_0^\infty \varphi(\rho) \frac{d\rho}{\rho} \int_{(0,\infty)^{n-1}} \phi \prod_i \frac{d\varepsilon_i}{\varepsilon_i},$$

the same holds with $|\phi|$, and with ϕ whenever the integrals of $|\phi|$ are finite. With $h = |\alpha|$, Lemma 2.7 on $\mathcal{E}$ writes the left side as $\int_0^\infty \varphi(\rho) \frac{d\rho}{\rho} \int_{\Delta_{\mathcal{E}}} \phi(u) u^{-\mathbf{1}} d\omega_{\mathcal{E}}(u)$. With $h = |\alpha_R|$, Lemma 2.7 on B and on R, $\alpha_B = \rho' u$ and $\alpha_R = \lambda u'$, gives $\alpha^{-\mathbf{1}} d\alpha = u^{-\mathbf{1}} u'^{-\mathbf{1}} \frac{d\rho'}{\rho'} \frac{d\lambda}{\lambda} d\omega_B(u) d\omega_R(u')$ and $\phi(\rho' u, \lambda u') = \phi(\rho u, u')$ with $\rho' = \lambda\rho$, so the left side is the third expression times $\int \varphi(\lambda) d\lambda/\lambda$. A φ with $\int_0^\infty \varphi\, d\rho/\rho = 1$ gives the identities. In the chart $\Omega_{\mathcal{E}}/\alpha^{\mathcal{E}} = (-1)^{n-1} \bigwedge_i d\varepsilon_i/\varepsilon_i$ (proof of Lemma 34.3(iii)), which with the orientation of $\widetilde{\sigma}^\circ_{\mathcal{E}} = (0,\infty)^{n-1}$ is the measure $\prod_i d\varepsilon_i/\varepsilon_i$. If the form is regular near the compact $\widetilde{\sigma}_{\mathcal{E}}$, it is $g\, d\varepsilon$ on each sector cube with g continuous on the cube; so its integral over each sector converges absolutely, the sectors cover $\widetilde{\sigma}_{\mathcal{E}}$ and meet in sets of measure zero, and $\widetilde{\sigma}_{\mathcal{E}} \setminus \widetilde{\sigma}^\circ_{\mathcal{E}}$ lies in the coordinate hyperplanes of the charts (Lemma 34.3(i)). □

Lemma S16 (The continued period off the balance wall)**.** *Let F be a family of lists on $\mathcal{E}$, $n \geq 2$. For an order π with the chain $(S_i^\pi)_{i<n}$ let $\widetilde{K}_j, \widetilde{\Psi}_j$ and $\widetilde{L}_\pi$ be the sector letters of K_j, Ψ_j and of the linear letter $\alpha_{\mathcal{E}} = |\alpha|$ in its chart (Lemma 34.3(ii)), and $h_\pi(\varepsilon; \kappa, \mathbf{s}, \mathbf{t}) = \widetilde{L}_\pi^{-\kappa} \prod_j \widetilde{K}_j^{-s_j} \widetilde{\Psi}_j^{-t_j}$. As meromorphic functions of $(\mathbf{m}, \mathbf{s}, \mathbf{t}) \in \mathbb{C}^{\mathcal{E}} \times \mathbb{C}^N \times \mathbb{C}^N$,*

$$\frac{J_F(\mathbf{m}; \mathbf{s}, \mathbf{t})}{\Gamma(\kappa_{\mathcal{E}})} = \sum_\pi \operatorname{cube}\Big(\big(\kappa_{S_i^\pi}\big)_{i<n},\ (\kappa_{\mathcal{E}}, \mathbf{s}, \mathbf{t});\ h_\pi\Big),$$

with cube *the cube integral of Lemma 8.4; the right side is holomorphic off the hyperplanes $\kappa_S = -j$, $\varnothing \neq S \subsetneq \mathcal{E}$, $j \in \mathbb{N}$. So the period $P_F = J_F/\Gamma(\kappa_{\mathcal{E}})$ (Theorem 8.7) has its poles on these hyperplanes only, and on the balance wall it is the right side at $\kappa_{\mathcal{E}} = 0$, where $h_\pi = \prod_j \widetilde{K}_j^{-s_j} \widetilde{\Psi}_j^{-t_j}$.*

Proof. On the region where $\operatorname{Re} \kappa_S > 0$ for every nonempty $S \subseteq \mathcal{E}$, which contains the points with $\mathbf{s} = \mathbf{t} = 0$ and $\operatorname{Re} \mathbf{m} > 0$, Theorem 8.5(ii) is the display, read in the chart coordinates as in the proof of Lemma 34.3(ii): its sector letters $k_{j,\pi}, \psi_{j,\pi}, L_\pi$ are $\widetilde{K}_j, \widetilde{\Psi}_j, \widetilde{L}_\pi$. The sector letters are at least 1 on the cube, so h_π is smooth in ε near $[0,1]^{n-1}$, with every ε-derivative continuous in all the variables and holomorphic in $(\kappa, \mathbf{s}, \mathbf{t}) \in \mathbb{C}^{1+2N}$. The map $(\mathbf{m}, \mathbf{s}, \mathbf{t}) \mapsto \big((\kappa_{S_i^\pi})_{i<n}, \kappa_{\mathcal{E}}, \mathbf{s}, \mathbf{t}\big)$ is a linear isomorphism of $\mathbb{C}^{\mathcal{E}} \times \mathbb{C}^{2N}$, since $\mathbf{m} \mapsto (m_{S_1^\pi}, \ldots, m_{S_{n-1}^\pi}, m_{\mathcal{E}})$ is triangular. Lemma 8.4 continues

each term to a meromorphic function on the whole space with poles on the hyperplanes $\kappa_{S_i^\pi} = -j$ only. The sum agrees with the meromorphic $J_F/\Gamma(\kappa_\mathcal{E})$ (Theorems 8.5(iii) and 8.7) on a nonempty open set, hence everywhere. At $\kappa_\mathcal{E} = 0$, $\widetilde{L}_\pi^{-\kappa_\mathcal{E}} = 1$. □

Proposition 34.4 (The model). *As stated.*

Proof. (i) $\widetilde{\sigma}_\mathcal{E}$ is the union of the finitely many sectors, cubes (Lemma 34.3(i)), so it is compact. In a chart $\widetilde{\sigma}_\mathcal{E} \cap U = [0,\infty)^{n-1}$ and $\widetilde{\sigma}_\mathcal{E}^\circ = (0,\infty)^{n-1}$, whose difference lies in the coordinate hyperplanes, that is in D; and the charts cover $X_\mathcal{E}$. For a letter f of a list or a linear letter, $\widetilde{Y}_f \cap U = \{\widetilde{f} = 0\}$ and $\widetilde{f} \geq 1$ on $[0,\infty)^{n-1}$ (Lemma 34.3(ii)).

(ii) Let $\varnothing \neq S \subsetneq \mathcal{E}$ and take an order whose chain contains $S = S_i$. D_S meets V_F: the face $\{\varepsilon_i = 0\} \cap [0,1]^{n-1}$ of the sector cube lies in $D_S \cap \widetilde{\sigma}_\mathcal{E}$, and $\widetilde{\sigma}_\mathcal{E} \subseteq V_F(\mathbb{R})$ by (i). On $V_F \cap U$ every $\widetilde{K}_j$ with $s_j \neq 0$ and every $\widetilde{\Psi}_j$ with $t_j \neq 0$ is a unit, V_F omitting their zero sets, so by Lemma 34.3(iii) ω_F is a unit times $\prod_k \varepsilon_k^{\kappa_{S_k}-1} d\varepsilon_1 \wedge \cdots \wedge d\varepsilon_{n-1}$ there. Its order along D_S, read at a point of $D_S \cap V_F \cap U$, is $\kappa_S - 1$, and on the torus, where every ε_k is a unit, it has neither zeros nor poles. A prime divisor of V_F either meets the torus or is one of the $D_S \cap V_F$, each irreducible as a nonempty open subset of the irreducible D_S. So the divisor of ω_F on the smooth V_F is $\sum_S (\kappa_S - 1)(D_S \cap V_F)$, and ω_F is regular exactly when this divisor is effective, that is when F is convergent. On the cube of a sector, $\omega_F = \pm \prod_k \varepsilon_k^{\kappa_{S_k^\pi}-1} h_\pi \, d\varepsilon$ with $h_\pi = \prod_j \widetilde{K}_j^{-s_j} \widetilde{\Psi}_j^{-t_j}$ positive and continuous on the compact cube, so bounded between two positive constants; as $\int_0^1 \varepsilon^{\kappa-1} d\varepsilon$ converges for $\kappa \geq 1$, the integral over $\widetilde{\sigma}_\mathcal{E}$ converges when F is convergent. By Lemma S15 it is the integral over $\Delta_\mathcal{E}$ of $u^{\mathbf{m}-\mathbf{1}} \prod_j K_j^{-s_j} \Psi_j^{-t_j}$, the period (Theorem 8.7), positive with the orientation in which $\Omega_\mathcal{E}/\alpha^\mathcal{E}$ is positive on $\widetilde{\sigma}_\mathcal{E}^\circ$.

(iii) V_F is open in the smooth $X_\mathcal{E}$. The complement in $X_\mathcal{E}$ of the $\widetilde{Y}_{\alpha_J}$, $|J| \geq 2$, is Brown's affine model (Brown, *Feynman amplitudes*, §5), which applies because $X_\mathcal{E}$ is the iterated blow-up of $\mathbb{P}(\mathbb{Q}^\mathcal{E})$ along its coordinate linear subspaces, the toric variety of the subdivision of its fan by all chains, and the removed hypersurfaces are the strict transforms of the hyperplanes $\alpha_J = 0$ of all the sets J of at least two marks. In toric terms the divisor $A = \sum_{|J|\geq 2} \widetilde{Y}_{\alpha_J}$ is ample. In the chart of an order, $\alpha_J/\alpha_y = \widetilde{\alpha}_J$ for the last mark y of J in the order (Lemma 34.3(ii)), so $\widetilde{Y}_{\alpha_J}$ is the divisor of the section $\sum_{e\in J} \alpha^{\mathbf{e}_e}$ of the line bundle of the simplex $\Delta_J = \operatorname{conv}\{\mathbf{e}_e : \ e \in J\}$, whose vertex of least value on the cone of the order is $\mathbf{e}_y$; A is then the divisor of a section of the line bundle of the polytope $\sum_J \Delta_J$, whose vertex of least value on the interior of the cone of the order $e_1, \ldots, e_n$ is $\sum_J \mathbf{e}_{y_J} = \sum_k (2^{k-1} - 1)\, \mathbf{e}_{e_k}$, the mark e_k being the last mark of $2^{k-1} - 1$ sets J; it is the only point of least value there and differs for different orders. So the normal fan of $\sum_J \Delta_J$ is the braid fan, the divisor A is ample (Fulton, Chapter 3), a multiple of it is a hyperplane section in a projective embedding, and its complement is affine. A finite set $\mathcal{G}$ of polynomials that contains the α_J removes in addition the $\widetilde{Y}_g$, $g \in \mathcal{G}$, divisors of the smooth $X_\mathcal{E}$, hence Cartier divisors; the complement of a Cartier divisor in an affine variety is affine, the inclusion being locally the complement of the zero set of one function. D_F is the restriction of D to the open V_F, with simple normal crossings and smooth components (Lemma 34.3(i)). A stratum is an intersection of components meeting transversally, so smooth, and closed in the affine V_F, so affine.

(iv) Let τ be the cone of the flag. By the orbit–cone correspondence (Fulton, Chapter 3), $D_{S_1} \cap \cdots \cap D_{S_\ell}$ is the toric variety of the star of τ, the fan in $N/(N \cap \mathbb{R}\tau)$ of the images of the cones that contain τ. Restriction to the steps, $\mathbf{x} \mapsto (\mathbf{x}|_{Z_i} \bmod \mathbb{Z}\mathbf{1}_{Z_i})_i$, maps $\mathbb{Z}^\mathcal{E}$ onto $\bigoplus_i \mathbb{Z}^{Z_i}/\mathbb{Z}\mathbf{1}_{Z_i}$ with the kernel spanned by $\mathbf{1}_{Z_1}, \ldots, \mathbf{1}_{Z_{\ell+1}}$, that is by $\mathbf{1}_{S_1}, \ldots, \mathbf{1}_{S_\ell}$ and $\mathbf{1}$; a set S with $S_{i-1} \subsetneq S \subsetneq S_i$ goes to $\mathbf{1}_{S\setminus S_{i-1}}$ in the summand of Z_i and to 0 in the others. So the cones of the chains that refine the flag go to the products of cones of chains of the steps, the star of τ is the product of the braid

fans of the steps, and $D_{S_1} \cap \cdots \cap D_{S_\ell} \cong \prod_i X_{Z_i}$. The charts that meet the stratum are those of the orders whose chains contain the flag; in such a chart the stratum is $\{\varepsilon_i = 0 :\ i \in I\}$, I the positions of the sets of the flag, and the remaining coordinates are the chart coordinates of the steps. By Lemma 34.3(ii) $\widetilde{Y}_f$ meets it in the union over the steps Z of the zero sets of the polynomials attached to the step letters of f at Z, and by the same lemma on Z these are the $\widetilde{Y}_g \cap U_Z$ for the step letters g, empty for a monomial. The step letters at Z of the augmented letters of F that are not monomials form $\mathrm{Let}(Z;\mathfrak{f})$: the step letter of α_J is $\alpha_{J\cap Z}$ at the first step Z with $J \subseteq S_b$ and 1 elsewhere, and every $\alpha_{J'}$ with $J' \subseteq Z$, $|J'| \geq 2$, arises from $J = J'$. So the stratum of $\mathfrak{f}$ is $\prod_i V_{Z_i;\mathfrak{f}}$. Its boundary, its meeting with the D_S of the sets S outside the flag, is $\{\varepsilon_k = 0\}$ for the other positions k, the union of the pull-backs of the toric boundaries of the factors; and $\widetilde{\sigma}_{\mathcal{E}}$ meets it in $[0,\infty)^{n-1} \cap \{\varepsilon_i = 0 :\ i \in I\} = \prod_Z [0,\infty)^{|Z|-1}$, chart by chart, that is in $\prod_i \widetilde{\sigma}_{Z_i}$.

(v) Where every proper wall has positive real part the period converges (Theorem 8.7), and by Lemma S15, the sectors and Lemma 34.3(iii) it is $\sum_\pi \int_{[0,1]^{n-1}} \prod_i \varepsilon_i^{\kappa_{S_i^\pi}-1} h_\pi \, d\varepsilon = \sum_\pi \mathrm{cube}(\boldsymbol{\kappa}_\pi(\mathbf{m}); h_\pi)$, each term converging absolutely. By Lemma S16 the right side is, on the whole balance wall, the restriction of $J_F/\Gamma(\kappa_{\mathcal{E}})$, meromorphic there jointly in the masses and the exponents, with poles on the hyperplanes $\kappa_S = -j$ only. □

Definition 34.5 (Motivic periods; Galois conjugates; open spaces). As stated.

Proof. The motivic periods, the de Rham periods, their relations and the coaction are those of Brown's notes (§2 and §3.1), where the coaction is shown to be well defined. For a convergent family, (V_F, D_F) is a pair with V_F affine (Proposition 34.4(iii)), so H_F is an object of Brown's category; $\widetilde{\sigma}_{\mathcal{E}}$ is a relative cycle of it, compact, the closure of the open cell, with $\widetilde{\sigma}_{\mathcal{E}} \setminus \widetilde{\sigma}^\circ_{\mathcal{E}} \subseteq D_F$ and $\widetilde{\sigma}_{\mathcal{E}} \subseteq V_F(\mathbb{R})$ (Proposition 34.4(i)); and ω_F is a regular form of degree $n-1$ on V_F (Proposition 34.4(ii)), with its class $[\omega_F]$. The period of P_F^{mot} is $\int_{\widetilde{\sigma}_{\mathcal{E}}} \omega_F = P_F(\mathbf{m};\mathbf{s},\mathbf{t})$ (Proposition 34.4(ii)). For a step with $|Z| \geq 2$ the letters of the step are letters of lists on Z and the α_J, $J \subseteq Z$, $|J| \geq 2$; so by Proposition 34.4(i) and (iii) on Z, $(V_{Z;\mathfrak{f}}, \partial V_{Z;\mathfrak{f}})$ is a pair with $V_{Z;\mathfrak{f}}$ affine and $\widetilde{\sigma}_Z$ is a relative cycle of it. □

Lemma 34.6 (Galois conjugates). *As stated.*

Proof. $\mathcal{P}^{\mathrm{dR}}$ is the ring of functions on the de Rham Galois group, $[M,f,\omega]^{\mathrm{dR}}$ being the function $g \mapsto f(g\,\omega)$ (Brown's notes, §2); evaluation at the identity is a $\mathbb{Q}$-linear map $\varphi_1 : \mathcal{P}^{\mathrm{dR}} \to \mathbb{Q}$ with $\varphi_1([M,f,\omega]^{\mathrm{dR}}) = f(\omega)$.

(i) For $\xi = [M,\gamma,\omega]^{\mathrm{mot}}$, $(\mathrm{id}\otimes\varphi_1)\Delta\xi = \sum_i [M,\gamma,e_i]^{\mathrm{mot}}\, e_i^\vee(\omega) = [M,\gamma,\omega]^{\mathrm{mot}}$ by bilinearity; by linearity the same holds for every ξ.

(ii) $(\mathrm{id}\otimes\varphi)\Delta[M,\gamma,\omega]^{\mathrm{mot}} = \big[M,\gamma,\sum_i \varphi([M,e_i^\vee,\omega]^{\mathrm{dR}})\, e_i\big]^{\mathrm{mot}} \in L(M,\gamma)$, and the left factors of the coaction of an element of $L(M,\gamma)$ lie in $L(M,\gamma)$.

(iii) $\mathrm{C}(\xi)$ is the image of the linear map $\varphi \mapsto (\mathrm{id}\otimes\varphi)\Delta\xi$, a space; so $\mathrm{C}(\xi+\xi') \subseteq \mathrm{C}(\xi)+\mathrm{C}(\xi')$ and $\mathrm{C}(q\,\xi) = q\,\mathrm{C}(\xi) = \mathrm{C}(\xi)$ for $q \neq 0$. Write $\Delta\xi = \sum_i \xi_i \otimes \xi_i'$ with the ξ_i' linearly independent; a φ with $\varphi(\xi_k')$ equal to 1 for $k = i$ and to 0 otherwise shows $\xi_i \in \mathrm{C}(\xi)$. Likewise $\Delta\xi' = \sum_k \eta_k \otimes \eta_k'$ with $\eta_k \in \mathrm{C}(\xi')$. The coaction is a homomorphism of rings (Brown's notes, §2), so $(\mathrm{id}\otimes\varphi)\Delta(\xi\xi') = \sum_{i,k} \xi_i\eta_k\, \varphi(\xi_i'\eta_k') \in \mathrm{C}(\xi)\cdot\mathrm{C}(\xi')$. □

Lemma 34.7 (Birational invariance). *As stated.*

Proof. The resolution. Let $\Gamma \subseteq X_1 \times X_2$ be the closure of the graph of Φ, a projective variety. The graph is closed in $U_1 \times X_2$, so $\Gamma \cap (U_1 \times X_2)$ is the graph; it is also the graph of Φ^{-1}, closed in $X_1 \times U_2$, so $\Gamma \cap (X_1 \times U_2)$ is the graph too; and the graph, isomorphic to U_1, is a smooth dense

open subset of Γ. By resolution of singularities in characteristic zero (Hironaka), in the form that gives for a projective variety and a smooth dense open subset of it a smooth projective variety with a proper birational morphism onto it that is an isomorphism over that subset and under which the complement pulls back to a divisor with simple normal crossings and smooth components, there is such a $\varpi : \widetilde{X} \to \Gamma$ for the graph; the property used is that the graph of Φ is smooth and the ground field $\mathbb{Q}$ has characteristic zero. Let $q_i : \widetilde{X} \to X_i$ be the two projections; by the above $q_1^{-1}(U_1) = q_2^{-1}(U_2) = \varpi^{-1}(\text{graph})$, on which q_1 and $q_2 = \Phi \circ q_1$ are isomorphisms onto U_1 and U_2. Put $\widetilde{D}_i = q_i^{-1}(D_i)$ and $\widetilde{Y} = q_1^{-1}(Y_1) \cup q_2^{-1}(Y_2)$, both closed. A point of $\widetilde{D}_1$ is not over the graph, D_1 missing U_1; so $\widetilde{D}_1$, the support of the pull-back of a Cartier divisor under the dominant q_1, is a divisor contained in the divisor $\varpi^{-1}(\Gamma \setminus \text{graph})$ and so a union of its components; likewise $\widetilde{D}_2$ and $\widetilde{D}_1 \cup \widetilde{D}_2$. All three have simple normal crossings and smooth components.

The cycle. Let $\widetilde{\sigma}$ be the closure in $\widetilde{X}(\mathbb{R})$ of $\widetilde{\sigma}^\circ = q_1^{-1}(\sigma_1^\circ)$, which q_1 maps isomorphically onto σ_1° and q_2 onto σ_2°; orient it by q_1. It is compact, and $q_i(\widetilde{\sigma}) = \sigma_i$, which misses Y_i; so $\widetilde{\sigma}$ misses $\widetilde{Y}$. If $x \in \widetilde{\sigma} \setminus \widetilde{\sigma}^\circ$ had $q_1(x) \in \sigma_1^\circ \subseteq U_1$, x would lie over the graph, where q_1 is injective, and so in $\widetilde{\sigma}^\circ$; hence $q_1(x) \in \sigma_1 \setminus \sigma_1^\circ \subseteq D_1$ and $x \in \widetilde{D}_1$. The same argument with q_2 and $\Phi(\sigma_1^\circ) = \sigma_2^\circ$ gives $x \in \widetilde{D}_2$. So $\widetilde{\sigma}$ is a relative cycle of $(\widetilde{X} \setminus \widetilde{Y}, \widetilde{D}_i \setminus \widetilde{Y})$ for $i = 1, 2$ and of $(\widetilde{X} \setminus \widetilde{Y}, (\widetilde{D}_1 \cup \widetilde{D}_2) \setminus \widetilde{Y})$, and q_i carries its class to that of σ_i, mapping $\widetilde{\sigma}^\circ$ onto σ_i° with the orientation, Φ preserving it, and $\widetilde{\sigma} \setminus \widetilde{\sigma}^\circ$ into D_i.

The form. $q_1^*\omega_1$ and $q_2^*\omega_2$ are rational forms on $\widetilde{X}$ that agree on the dense open $q_1^{-1}(U_1)$, where $q_2 = \Phi \circ q_1$ and $\Phi^*\omega_2 = \omega_1$; so they are one form $\widetilde{\omega}$, regular off $q_1^{-1}(Y_1)$ and off $q_2^{-1}(Y_2)$, hence on $\widetilde{X} \setminus \widetilde{Y}$.

The chain of pairs. The maps

$$(X_1^\circ, D_1^\circ) \xleftarrow{q_1} (\widetilde{X} \setminus \widetilde{Y}, \widetilde{D}_1 \setminus \widetilde{Y}) \xrightarrow{\mathrm{id}} \big(\widetilde{X} \setminus \widetilde{Y}, (\widetilde{D}_1 \cup \widetilde{D}_2) \setminus \widetilde{Y}\big) \xleftarrow{\mathrm{id}} (\widetilde{X} \setminus \widetilde{Y}, \widetilde{D}_2 \setminus \widetilde{Y}) \xrightarrow{q_2} (X_2^\circ, D_2^\circ)$$

are morphisms of pairs, so their maps on relative cohomology are morphisms of Brown's category (Huber and Müller-Stach). Each pulls back the class of the form of degree m to the class of the pulled-back form, and its transpose carries the class of $\widetilde{\sigma}$, or of σ_1, σ_2 at the ends, to the class of the cycle at its target. The relation $[M, \phi^{\mathrm{t}}\gamma', \omega]^{\mathrm{mot}} = [M', \gamma', \phi(\omega)]^{\mathrm{mot}}$ along the four morphisms gives

$$\big[H^m(X_1^\circ, D_1^\circ), \sigma_1, \omega_1\big]^{\mathrm{mot}} = \big[H^m(\widetilde{X} \setminus \widetilde{Y}, \widetilde{D}_1 \setminus \widetilde{Y}), \widetilde{\sigma}, \widetilde{\omega}\big]^{\mathrm{mot}} = \cdots = \big[H^m(X_2^\circ, D_2^\circ), \sigma_2, \omega_2\big]^{\mathrm{mot}}.$$

The particular cases. With $X_1 = X_2$, $D_1 = D_2$, $Y_2 \supseteq Y_1$ closed and missing σ_1, $U_1 = U_2 = X_1 \setminus (D_1 \cup Y_2)$ and Φ the identity, the hypotheses hold, σ_1° lying in $U_1(\mathbb{R})$. For a convergent family, ω_F is regular on $X_{\mathcal{E}} \setminus \bigcup_{f \in \mathrm{Let}(F)} \widetilde{Y}_f$, by the proof of Proposition 34.4(ii), which uses only that the letters of F are units there; and V_F removes in addition the $\widetilde{Y}_{\alpha_J}$, which miss $\widetilde{\sigma}_{\mathcal{E}}$ (Proposition 34.4(i)). Two convergent families F, F' on $\mathcal{E}$ with $\omega_F = \omega_{F'}$ give $X_1 = X_2 = X_{\mathcal{E}}$, $D_1 = D_2 = D$, Y_1 and Y_2 the unions of the $\widetilde{Y}_f$ over the augmented letters of F and of F', both missing $\widetilde{\sigma}_{\mathcal{E}}$, $U_1 = U_2$ the torus less $Y_1 \cup Y_2$ and Φ the identity. □

Lemma S17 (Products of pairs)**.** *For $i = 1, \dots, p$ let (V_i, D_i) be a pair of dimension m_i with a relative cycle σ_i and a regular form η_i of degree m_i on V_i. Let $V = \prod_i V_i$, $D = \bigcup_i \mathrm{pr}_i^{-1}(D_i)$, $\sigma = \prod_i \sigma_i$ with the product orientation, and $\eta = \mathrm{pr}_1^*\eta_1 \wedge \cdots \wedge \mathrm{pr}_p^*\eta_p$. Then (V, D) is a pair, σ is a relative cycle of it, and, with $m = \sum_i m_i$,*

$$\big[H^m(V, D), \sigma, [\eta]\big]^{\mathrm{mot}} = \prod_{i=1}^{p} \big[H^{m_i}(V_i, D_i), \sigma_i, [\eta_i]\big]^{\mathrm{mot}}.$$

Proof. In products of local coordinates D is a union of coordinate hyperplanes of the factors, so (V, D) is a pair; σ is the closure of the oriented $\prod_i \sigma_i^\circ$, of dimension m, and $\sigma \setminus \prod_i \sigma_i^\circ \subseteq D$. The cross product $\mu : \bigotimes_i H^{m_i}(V_i, D_i) \to H^m(V, D)$ is a morphism of Nori's category (Huber and Müller-Stach), hence of Brown's; on de Rham realizations it carries $\bigotimes_i [\eta_i]$ to $[\eta]$, and its transpose carries σ to $\bigotimes_i \sigma_i$, the class of a product of relative cycles being the cross product of their classes; on forms this is Fubini, $\int_\sigma \mathrm{pr}_1^* \theta_1 \wedge \cdots \wedge \mathrm{pr}_p^* \theta_p = \prod_i \int_{\sigma_i} \theta_i$. The relation of Definition 34.5 for μ, with the product of motivic periods defined by the tensor product of objects (Brown's notes, §2), gives the identity. □

Corollary 34.8 (Cremona between motivic periods). *As stated.*

Proof. The walls. With $d(S) = r - r(\mathcal{E} \setminus S)$, $d^*(S) = |S| - r(S)$, $d(\mathcal{E} \setminus S) = r - r(S)$ and $d^*(\mathcal{E} \setminus S) = |\mathcal{E} \setminus S| - r(\mathcal{E} \setminus S)$ in every table (Definition 7.12), and $m_\mathcal{E} = \sum_j (s_j r_j + t_j(n - r_j))$ on the balance wall,

$$\kappa_S(F^\mathrm{c}) = 2\sigma|S| - m_S - \sum_j t_j\big(r_j - r_j(\mathcal{E} \setminus S)\big) - \sum_j s_j\big(|S| - r_j(S)\big),$$
$$\kappa_{\mathcal{E}\setminus S}(F) = m_\mathcal{E} - m_S - \sum_j s_j\big(r_j - r_j(S)\big) - \sum_j t_j\big(n - |S| - r_j(\mathcal{E} \setminus S)\big),$$

and both equal $-m_S + \sum_j s_j r_j(S) + \sum_j t_j\big(|S| - r_j + r_j(\mathcal{E} \setminus S)\big)$, using $2\sigma = \sum_j (s_j + t_j)$. At $S = \mathcal{E}$ the same computation gives $\kappa_\mathcal{E}(F^\mathrm{c}) = -\kappa_\mathcal{E}(F) = 0$. So F^c is on its balance wall, at integer data, and convergent with F.

The forms. Let Φ be the inversion $\alpha \mapsto \alpha^{-1}$ of the torus, an automorphism that maps $\widetilde{\sigma}_\mathcal{E}^\circ$ onto itself. By Proposition 7.2, $K_j(\alpha^{-1}) = \alpha^{-\mathcal{E}} \Psi_j(\alpha)$ and $\Psi_j(\alpha^{-1}) = \alpha^{-\mathcal{E}} K_j(\alpha)$, and $\Phi^*(\Omega_\mathcal{E}/\alpha^\mathcal{E}) = (-1)^{n-1} \Omega_\mathcal{E}/\alpha^\mathcal{E}$, every $d \log \alpha_e$ changing sign. So

$$\Phi^* \omega_{F^\mathrm{c}} = \alpha^{\mathbf{m} - 2\sigma\mathbf{1}}\, \alpha^{2\sigma\mathbf{1}} \prod_j K_j^{-s_j} \Psi_j^{-t_j}\, (-1)^{n-1} \frac{\Omega_\mathcal{E}}{\alpha^\mathcal{E}} = (-1)^{n-1} \omega_F,$$

the factor $\alpha^{2\sigma\mathbf{1}}$ collecting the powers $\alpha^\mathcal{E}$ of the letters, $\sum_j (s_j + t_j) = 2\sigma$. Let U_1 be the torus less the zero sets of the augmented letters of F and the preimages under Φ of those of F^c, and $U_2 = \Phi(U_1)$; these polynomials are positive at the positive points, so $\widetilde{\sigma}_\mathcal{E}^\circ \subseteq U_1(\mathbb{R})$. The periods P_F and $P_{F^\mathrm{c}} = \int \omega_{F^\mathrm{c}}$ over the positively oriented cell are both positive, so Φ maps the oriented $\widetilde{\sigma}_\mathcal{E}^\circ$ onto itself with the sign $(-1)^{n-1}$ of the forms; reversing the orientation of the target cell and the sign of ω_{F^c} together when that sign is -1, Lemma 34.7 applies to $(X_\mathcal{E}, D, Y_F)$ and $(X_\mathcal{E}, D, Y_{F^\mathrm{c}})$, Y the unions of the $\widetilde{Y}_f$ over the augmented letters, and gives $P_{F^\mathrm{c}}^\mathrm{mot} = P_F^\mathrm{mot}$ by bilinearity. □

Definition 34.9 (Attachment). As stated.

Proof. Every vertex of a tree of bunches is a split vertex, a node that is not a leaf, or a leaf (Definition 20.7), and the first two have children: the molecules of a split vertex, and the room of a node. Along the descent $Z \subseteq M_w$ at every vertex w reached: this holds at the root, a split vertex passes Z to the child that contains it, and a node passes Z to its room only when $Z \subseteq M_w \setminus B_w$, the marks of the room. At each vertex exactly one rule applies, Z being nonempty, and the vertex reached next has fewer marks: a child of a split vertex is one of at least two molecules, and $B_w \neq \varnothing$. So the descent ends, and it ends exactly where Z is attached. □

Lemma 34.10 (The letters of an attached step). *As stated.*

Proof. For a vertex w on the descent of Z say that Z *is read at* w when every letter of the step other than the linear letters is K, respectively Ψ, of the child at a pattern of $M_w \setminus Z$ of a table at w that carries K, respectively Ψ. At the root it holds: the step lists of $\mathcal{B}_j$ at Z are the children $\mathcal{B}_{j,(T_0\setminus Z)}$ and $\mathcal{B}_{j,(T_1\setminus Z)}$ at patterns of $\mathcal{E}\setminus Z$ (Proposition 12.20), or $\mathcal{B}_j$ itself when $Z=\mathcal{E}$, and the tables at the root are the active tables of F, $\mathcal{B}_j$ carrying K exactly when $s_j\neq 0$ and Ψ exactly when $t_j\neq 0$. Let it hold at w, and let the descent pass to a child w'.

At a split vertex, $Z\subseteq M'$ for a molecule M', and every table N at w is the direct sum of its restrictions to the molecules (Proposition 7.9). So the bases of N with a given trace p on $M_w\setminus Z$ have their other parts fixed, and the child of N at p is the child of $N|M'$ at the pattern $p\cap M'$ of $M'\setminus Z$; $N|M'$ is a table at w' with the exponents of N.

At a node that is not a leaf, $Z\subseteq M_w\setminus B_w$. A pattern p of $M_w\setminus Z$ in a table N at w is $p_B\sqcup p_R$ with $p_B=p\cap B_w$ a pattern of B_w and $p_R\subseteq (M_w\setminus B_w)\setminus Z$, and the bases T of N with $T\setminus Z=p$ are those with $T\cap B_w=p_B$ whose parts $T\setminus B_w$, bases of the child $N_{(p_B)}$, have the trace p_R on $(M_w\setminus B_w)\setminus Z$. So the child of N at p is the child of $N_{(p_B)}$ at p_R (Proposition 14.5). $N_{(p_B)}$ is a table made at w, carrying the letters N carries with exponents that are positive multiples of those of N (Definition 20.7); it is a table of the room, of the one childcule when the room is a node and of the split vertex otherwise.

So Z is read at the vertex where it is attached, which is the statement. □

Lemma 34.11 (One form carries every period). *As stated.*

Proof. Number the components $D_1,\dots,D_K$ of D and put $D_I=\bigcap_{k\in I}D_k$, $D_\varnothing=V$; each D_I is smooth of dimension $m-|I|$ or empty, and closed in the affine V, so affine. The relative de Rham cohomology $H^\bullet_{\mathrm{dR}}(V,D)$ is the hypercohomology of the double complex $\Omega^\bullet_V\to\bigoplus_{|I|=1}\Omega^\bullet_{D_I}\to\bigoplus_{|I|=2}\Omega^\bullet_{D_I}\to\cdots$ with the alternating restrictions (Brown's notes, §10; Huber and Müller-Stach). Its terms are coherent sheaves on the affine V, with no higher cohomology, so it is the cohomology of the total complex of global sections, $\mathrm{Tot}^q=\bigoplus_I\Omega^{q-|I|}(D_I)$. Since $\Omega^q(D_I)=0$ for $q>m-|I|$, $\mathrm{Tot}^{m+1}=0$ and every $(\eta_I)_I\in\mathrm{Tot}^m$ is a cocycle, η_I a form of top degree on D_I. Let ℓ be the largest $|I|$ with $\eta_I\neq 0$, and suppose $\ell\geq 1$.

Restriction is onto. For $|I'|=\ell-1$, restriction maps $\Omega^{m-\ell}(D_{I'})$ onto $\bigoplus_{k\notin I'}\Omega^{m-\ell}(D_{I'}\cap D_k)$, the top forms on the boundary components of $D_{I'}$. In local coordinates of $D_{I'}$ in which the components $D_{I'}\cap D_k$ through a point are $\{z_1=0\},\dots,\{z_r=0\}$ and dw is the product of the differentials of the other coordinates, the form $\sum_t\widetilde{g}_t\,dz_1\wedge\cdots\widehat{dz_t}\cdots\wedge dz_r\wedge dw$ restricts to $\pm g_t\,dw$ on $\{z_t=0\}$, $\widetilde{g}_t$ any local extension of g_t, and to 0 on the others; so the map of coherent sheaves is onto, and so is its map on global sections, $D_{I'}$ being affine.

The deepest level removed. For $|I|=\ell$ let $I'=I\setminus\{\max I\}$. Choose $\gamma_{I'}\in\Omega^{m-\ell}(D_{I'})$ for every $|I'|=\ell-1$ restricting on $D_{I'\cup\{k\}}$, $k>\max I'$, to the form that cancels $\eta_{I'\cup\{k\}}$ in the total differential, and to 0 on the $D_{I'\cup\{k\}}$ with $k<\max I'$. In $(\eta)-d\gamma$ the entry at $|I|=\ell$ is η_I less the restrictions of the $\gamma_{I\setminus\{k\}}$, $k\in I$, of which only $k=\max I$ contributes, and it is 0; the entries above ℓ stay 0, and those at $\ell-1$ change by $d\gamma_{I'}$. By induction every class is the class of $(\eta_\varnothing,0,\dots,0)$, a regular m-form on V.

For a convergent family, (V_F,D_F) is such a pair (Proposition 34.4(iii)), and $V_{\mathcal{E};\varnothing\subsetneq\mathcal{E}}=V_F$, the letters of the one step $\mathcal{E}$ being the augmented letters of F that are not monomials, whose $\widetilde{Y}_f$ are empty; so $L(H_F,\widetilde{\sigma}_\mathcal{E})=\mathrm{Open}(\mathcal{E};\varnothing\subsetneq\mathcal{E})$. For a step with $|Z|\geq 2$ the same holds on Z (proof of Definition 34.5); for $|Z|=1$ both sides are $\mathbb{Q}$. □

Proposition 34.12 (Weight-graded faces). *As stated.*

Proof. For a chain $\mathfrak{c}$ of nonempty proper sets let $D_{\mathfrak{c}}$ be its stratum in V_F, a smooth affine variety of dimension $n-1-|\mathfrak{c}|$, nonempty since it meets $\widetilde{\sigma}_{\mathcal{E}}$ (Proposition 34.4(iii),(iv)), with its boundary $\partial D_{\mathfrak{c}}$, its meeting with the other components of D_F. The summands of the double complex of the proof of Lemma 34.11 over the chains refining $\mathfrak{c}$ form the double complex of $(D_{\mathfrak{c}}, \partial D_{\mathfrak{c}})$, shifted by $|\mathfrak{c}|$, and their inclusion is the *face map* $\phi_{\mathfrak{c}} : H^{n-1-|\mathfrak{c}|}(D_{\mathfrak{c}}, \partial D_{\mathfrak{c}}) \to H^{n-1}(V_F, D_F)$, a morphism of Brown's category whose transpose takes a relative cycle that is a manifold with corners, with its faces on the components of D_F, to its face on $D_{\mathfrak{c}}$, with a sign (Brown's notes, §10). Here $\widetilde{\sigma}_{\mathcal{E}}$ is such a cycle, $[0,\infty)^{n-1}$ in every chart, and $\phi_{\mathfrak{c}}^{\mathrm{t}}\widetilde{\sigma}_{\mathcal{E}} = \pm\widetilde{\sigma}_{\mathcal{E}} \cap D_{\mathfrak{c}}$. By Brown's weight-graded face maps (Brown's notes, §10), for $k < n-1$ the sum of the face maps of the chains with $n-1-|\mathfrak{c}| = k$ maps $\bigoplus_{\mathfrak{c}} W_k H^k(D_{\mathfrak{c}}, \partial D_{\mathfrak{c}})$ onto $W_k H^{n-1}(V_F, D_F)$; the property it needs is that every stratum is affine, so that its cohomology vanishes above its dimension. Write $e = \sum_{\mathfrak{c}} \phi_{\mathfrak{c}}(e_{\mathfrak{c}})$. By Lemma 34.11 on the pair $(D_{\mathfrak{c}}, \partial D_{\mathfrak{c}})$, $e_{\mathfrak{c}} = [\eta_{\mathfrak{c}}]$ for a regular k-form on $D_{\mathfrak{c}}$, and by the relation for $\phi_{\mathfrak{c}}$

$$[H_F, \widetilde{\sigma}_{\mathcal{E}}, e]^{\mathrm{mot}} = \sum_{\mathfrak{c}} \pm \big[H^k(D_{\mathfrak{c}}, \partial D_{\mathfrak{c}}), \widetilde{\sigma}_{\mathcal{E}} \cap D_{\mathfrak{c}}, [\eta_{\mathfrak{c}}]\big]^{\mathrm{mot}}.$$

The chain $\mathfrak{c}$ is a flag $\mathfrak{f}$ of dimension k, and by Proposition 34.4(iv) its stratum with its boundary is the product of the pairs $(V_{Z_i;\mathfrak{f}}, \partial V_{Z_i;\mathfrak{f}})$ over its steps, with $\widetilde{\sigma}_{\mathcal{E}} \cap D_{\mathfrak{c}} = \prod_i \widetilde{\sigma}_{Z_i}$. The factors are affine, so the regular functions on the product are the tensor product of those on the factors, the top forms likewise, and $\eta_{\mathfrak{c}}$ is a finite sum of products of top forms on the factors. By Lemma S17 each term is a product over the steps of elements of $\mathrm{Open}(Z_i;\mathfrak{f})$, a step of one mark giving a rational number; the signs are absorbed, $\mathrm{Open}(Z;\mathfrak{f})$ being closed under negation. □

Theorem 34.13 (Small steps along the tree). *As stated.*

Proof. Proposition 34.12 at $e = e_i$ is the inclusion. A flag of dimension k has $\sum_i (|Z_i| - 1) = k$, so each of its steps has at most $k+1$ marks. Each step is attached to exactly one vertex (Definition 34.9), and its letters are those of Lemma 34.10. □

Proposition 34.14 (Laurent coefficients are read on convergent data). *As stated.*

Proof. Meromorphy. The line $\mathbf{m} + \varepsilon\mathbf{v}$ lies in the balance wall, $v_{\mathcal{E}} = 0$, and $\kappa_S(\mathbf{m}+\varepsilon\mathbf{v}) = \kappa_S + \varepsilon v_S$ with $v_S \neq 0$, so the line meets every hyperplane $\kappa_S = -j$ in at most one point, and the continued period is meromorphic on it (Proposition 34.4(v)).

A relation at each wall. For lists every weight is 1. Let $\varnothing \neq S \subsetneq \mathcal{E}$. Summing the mark relations of Theorem 8.9(iii) over $e \in S$, and subtracting $s_j d_j(S)$ times the first letter relation of table j and $t_j d_j^*(S)$ times the second, for every j, gives, as meromorphic functions of the data,

$$\kappa_S\, P_F(\mathbf{m};\mathbf{s},\mathbf{t}) = \kappa_{\mathcal{E}} \sum_{e\in S} P_F(\mathbf{m}+\mathbf{e}_e;\mathbf{s},\mathbf{t}) + \sum_j s_j \sum_{T\in\mathcal{B}_j} \big(|T\cap S| - d_j(S)\big) P_F(\mathbf{m}+\mathbf{1}_T;\mathbf{s}+\mathbf{e}_j,\mathbf{t}) + \sum_j t_j \sum_{T\in\mathcal{B}_j} \big(|S\setminus T| - d_j^*(S)\big) P_F(\mathbf{m}+\mathbf{1}_{\mathcal{E}\setminus T};\mathbf{s},\mathbf{t}+\mathbf{e}_j).$$

Each term has its poles on the hyperplanes $\kappa_{S'} = -j$, S' proper, of its own data (Lemma S16), none of which contains the balance wall; so on the balance wall the first term vanishes, and the data of the other terms stay on it, $|T| = r_j$ and $|\mathcal{E}\setminus T| = r_j^*$. On the line $\mathbf{m}+\varepsilon\mathbf{v}$ every remaining term is meromorphic, as above, and

$$P_F(\mathbf{m}+\varepsilon\mathbf{v};\mathbf{s},\mathbf{t}) = \frac{1}{\kappa_S + \varepsilon v_S}\Big(\sum_j s_j \sum_T \big(|T\cap S| - d_j(S)\big) P_F(\mathbf{m}+\mathbf{1}_T+\varepsilon\mathbf{v};\mathbf{s}+\mathbf{e}_j,\mathbf{t})$$

$$+\sum_j t_j \sum_T \big(|S\setminus T| - d_j^*(S)\big) P_F(\mathbf{m}+\mathbf{1}_{\mathcal{E}\setminus T}+\varepsilon\mathbf{v};\mathbf{s},\mathbf{t}+\mathbf{e}_j)\Big),$$

with $1/(\kappa_S+\varepsilon v_S)\in\mathbb{Q}(\varepsilon)$ and integer coefficients.

The descent. Put $\delta(F)=\sum_{\varnothing\neq S\subsetneq\mathcal{E}}\max(0,1-\kappa_S)$, a nonnegative integer, zero exactly when F is convergent. If $\delta(F)>0$, choose S with $\kappa_S\leq 0$ and apply the relation at S, keeping the terms with nonzero coefficients. Their families are on the same tables, at integer data on their balance walls, with the exponents larger by one unit vector; their walls are $\kappa_{S'}+|T\cap S'|-d_j(S')\geq\kappa_{S'}$, respectively $\kappa_{S'}+|S'\setminus T|-d_j^*(S')\geq\kappa_{S'}$, for every S' (Theorem 7.13), and at S itself, the coefficient being nonzero, at least κ_S+1. As $1-\kappa_S\geq 1$, the term of S in δ drops by one, and δ drops by at least one. Repeating on every family with $\delta>0$ ends after finitely many steps, with convergent families F_k and coefficients $R_k\in\mathbb{Q}(\varepsilon)$, products of the factors above. The exponents only grow, so with $\mathbf{s},\mathbf{t}\geq 0$ every F_k has nonnegative exponents, and then positive masses, $m_e^{(k)}=\kappa_{\{e\}}(F_k)+\sum_j\big(s_j^{(k)}d_j(\{e\})+t_j^{(k)}d_j^*(\{e\})\big)\geq 1$, the singletons being proper as $n\geq 2$.

The coefficients. At the masses $\mathbf{m}^{(k)}+\varepsilon\mathbf{v}$ the walls of F_k have positive real parts for $|\varepsilon|$ small, so its period is the integral over $\Delta_{\mathcal{E}}$, converging absolutely and locally uniformly, holomorphic in ε, with the derivatives under the integral sign, $u^{\varepsilon\mathbf{v}}=\exp(\varepsilon\langle\mathbf{v},\log u\rangle)$. The displayed integrals converge absolutely: on $\Delta_{\mathcal{E}}$, $|\langle\mathbf{v},\log u\rangle|^l\leq C\prod_e u_e^{-\eta}$ for every $\eta>0$, and the walls at $\mathbf{m}^{(k)}-\eta\mathbf{1}$ are positive for small η, so that the integral of $u^{\mathbf{m}^{(k)}-\eta\mathbf{1}-\mathbf{1}}\prod_j K_j^{-s_j^{(k)}}\Psi_j^{-t_j^{(k)}}$ converges (Theorem 8.7, which reads the integral over $\Delta_{\mathcal{E}}$ off the balance wall as well). The Laurent coefficients of $\sum_k R_kP_{F_k}$ at 0 are rational combinations of the Taylor coefficients of the P_{F_k}, those of the R_k being rational. □

Corollary 34.15 (Open periods from families of lists). *As stated.*

Proof. The forms. The torus part of $V_{Z;\mathfrak{f}}$ is the torus less the zero sets of the letters of the step, a principal open subset of the torus, so a regular function on $V_{Z;\mathfrak{f}}$ is there a homogeneous Laurent polynomial divided by a product of powers of the letters, of total degree zero; and Ω_Z/α^Z is a nowhere vanishing form of top degree on the torus. Splitting the Laurent polynomial into its monomials writes η as a finite sum of terms $c_t\,\alpha^{\mathbf{a}_t}\prod_g g^{-k_{t,g}}\,\Omega_Z/\alpha^Z$, $k_{t,g}\in\mathbb{N}$, each the form ω_{F_t} of the family of the statement, a letter K of a step list being K of the table $(N;k_{t,g},0)$, a letter Ψ being Ψ of the table $(N;0,k_{t,g})$, and α_J being K of $(\binom{J}{1};k_{t,g},0)$ (Definition 34.1); $\alpha^{\mathbf{a}_t}\prod_g g^{-k_{t,g}}$ has degree zero, so F_t is on its balance wall.

The period. For $\mathbf{x}\in\mathbb{C}^Z$ with $x_Z=0$ near 0 put $G(\mathbf{x})=\int_{\widetilde{\sigma}_Z}\alpha^{\mathbf{x}}\eta$. In the chart of an order π, $\alpha^{\mathbf{x}}=\prod_i\varepsilon_i^{x_{S_i}}$ (proof of Lemma 34.3(ii)), and η, regular near $\widetilde{\sigma}_Z\subseteq V_{Z;\mathfrak{f}}(\mathbb{R})$ (proof of Definition 34.5), integrates over the sector as $g_\pi\,d\varepsilon$ on $[0,1]^{|Z|-1}$ with g_π smooth near the cube. So $G(\mathbf{x})=\sum_\pi\operatorname{cube}(\mathbf{x}_\pi+\mathbf{1};g_\pi)$, $\mathbf{x}_\pi=(x_{S_i^\pi})_i$, holomorphic near $\mathbf{x}=0$, and $G(0)=\int_{\widetilde{\sigma}_Z}\eta$ (Lemma S15). On the open cube Lemma 34.3(iii) gives, with the same sign for every t,

$$g_\pi=\sum_t c_t\,\varepsilon^{\boldsymbol{\kappa}_\pi(F_t)-\mathbf{1}}h_{t,\pi},\qquad h_{t,\pi}=\prod_g\widetilde{g}^{-k_{t,g}},$$

$\boldsymbol{\kappa}_\pi(F_t)$ the walls of F_t at $\mathbf{a}_t$ along the chain of π. Choose $A\in\mathbb{N}$ with $\boldsymbol{\kappa}_\pi(F_t)+A\mathbf{1}\geq\mathbf{1}$ for every t and π. The cube integrals have $\operatorname{cube}(\mathbf{y}+\mathbf{b};h)=\operatorname{cube}(\mathbf{y};\varepsilon^{\mathbf{b}}h)$ for $\mathbf{b}\in\mathbb{N}^{|Z|-1}$, where both converge and so, both sides being meromorphic (Lemma 8.4), everywhere; they are linear in h. So, as meromorphic functions of $\mathbf{x}$,

$$\sum_t c_t\operatorname{cube}\big(\mathbf{x}_\pi+\boldsymbol{\kappa}_\pi(F_t);h_{t,\pi}\big)=\sum_t c_t\operatorname{cube}\big(\mathbf{x}_\pi+(1-A)\mathbf{1};\varepsilon^{\boldsymbol{\kappa}_\pi(F_t)+(A-1)\mathbf{1}}h_{t,\pi}\big)$$

$$= \operatorname{cube}\big(\mathbf{x}_\pi + (1-A)\mathbf{1}; \varepsilon^{A\mathbf{1}} g_\pi\big) = \operatorname{cube}(\mathbf{x}_\pi + \mathbf{1}; g_\pi),$$

the functions $\varepsilon^{\boldsymbol{\kappa}_\pi(F_t)+(A-1)\mathbf{1}} h_{t,\pi}$ being smooth near the cube. Summing over π and using Proposition 34.4(v) with $\kappa_S(\mathbf{a}_t + \mathbf{x}) = \kappa_S(\mathbf{a}_t) + x_S$, $G(\mathbf{x}) = \sum_t c_t P_{F_t}(\mathbf{a}_t + \mathbf{x})$ as meromorphic functions near $\mathbf{x} = 0$ on $\{x_Z = 0\}$. On the line $\mathbf{x} = \varepsilon\mathbf{v}$, every v_S being nonzero, each term is meromorphic in ε, as in the proof of Proposition 34.14, the sum is $G(\varepsilon\mathbf{v})$, holomorphic at 0 with the value $\int_{\widetilde{\sigma}_Z} \eta$, and the constant term is linear.

The rest. Every F_t has nonnegative exponents, so Proposition 34.14 writes its constant term through convergent families of lists on Z with nonnegative integer exponents and positive integer masses, whose periods are values of the serif family (Proposition 8.12(i)), and their derivatives along $\mathbf{v}$. The period of $[H^{|Z|-1}(V_{Z;\mathfrak{f}}, \partial V_{Z;\mathfrak{f}}), \widetilde{\sigma}_Z, \eta]^{\mathrm{mot}}$ is $\int_{\widetilde{\sigma}_Z} \eta$, and taking periods is a homomorphism of rings; Theorem 34.13 gives the last sentence. □

Theorem 34.16 (The node form). *As stated.*

Proof. (i) A letter K of the step is K of a step list, which by Lemma 34.10 is the child N' of a table N at v at a pattern p of $M_v \setminus Z$, a list being determined by its basis polynomial; a letter Ψ is Ψ of such a child N', that is K of N'^* (Proposition 7.2); a letter α_J is K of $\binom{J}{1}$ read on Z, its marks outside J loops. Lemma 12.3, for the table N on M_v with the bunch $M_v \setminus Z$, its room Z, the pattern p, $A = Z_B$ and $W = B_v \setminus Z$, so that $A \cup W = B_v$, gives $c_{N'}(Z_B) \le c_N(B_v) \le c$; the dual has the same widths (Theorem 7.13). $\binom{J}{1}$ has rank at most one, so the width of Z_B in it is at most one. Finally $c \ge 1$: if every table at v had $c(B_v) = 0$, B_v would be a union of molecules of every table (Lemma 7.10), no circuit of a table at v would meet both B_v and $M_v \setminus B_v$, and B_v would be a union of molecules of the tables at v (Definition 7.4), against $\varnothing \ne B_v \subsetneq M_v$ and the tables at the node v forming one molecule.

(ii) For $g = K_{N_g}$ and the gauge (u, u'), $g(\rho u, u') = \sum_k \rho^k K^{(k)}_{Z_B}(u, u')$ over the levels $d_g \le k \le d_g + c_g$ (Definition 12.16, Theorem 7.13). The bases of the top level are the unions of a basis of $N_g|Z_B$ and one of N_g/Z_B, each of weight 1 (Theorem 12.19), so the top level letter is $K_{N_g|Z_B}(u)\, K_{N_g/Z_B}(u')$. The Skeleton polynomial $\mathsf{Q}^K_{Z_B}(x; (u, u')) = x^{-d_g} g(xu, u')/g(u, u') = \prod_i (x + \xi_{g,i})/(1 + \xi_{g,i})$ (Definition 12.10) shows that $\rho^{-d_g} g(\rho u, u')$ is a polynomial of degree c_g in ρ with the roots $-\xi_{g,i}$, and comparing leading coefficients gives the display. The Skeleton values of $K_{N''^*}$ along Z_B are those of $\Psi_{N''}$ (Definition 12.10), so the union over the letters is the joint spectrum of Z_B in the sense of Definition 12.14 and Theorem 15.3.

(iii) By Corollary 34.15, on the torus $\eta = \phi\, \Omega_Z/\alpha^Z$ with $\phi = \sum_t c_t \alpha^{\mathbf{a}_t} \prod_g g^{-k_{t,g}}$, homogeneous of degree zero. By Lemma S15 for the partition $Z = Z_B \sqcup Z_R$, $\int_{\widetilde{\sigma}_Z} \eta$ is the absolutely convergent integral over $\Delta_{Z_B} \times \Delta_{Z_R} \times (0, \infty)$ of $\phi(\rho u, u')\rho^{-1} u^{-\mathbf{1}} u'^{-\mathbf{1}}$. By (ii) the term t of this integrand is

$$A_t(u)\, B_t(u')\, \rho^{\nu_t - 1} \prod_{g,i} \big(\rho + \xi_{g,i}\big)^{-k_{t,g}},$$

with $A_t = c_t\, u^{\mathbf{a}_t|_{Z_B} - \mathbf{1}} \prod_g K_{N_g|Z_B}^{-k_{t,g}}$, $B_t = u'^{\mathbf{a}_t|_{Z_R} - \mathbf{1}} \prod_g K_{N_g/Z_B}^{-k_{t,g}}$ and $\nu_t = \sum_{e \in Z_B} a_{t,e} - \sum_g k_{t,g} d_g$. By Tonelli, for almost every (u, u') the integral over ρ of the sum converges absolutely, and the integral over $\Delta_{Z_B} \times \Delta_{Z_R}$ of it is the period, with an integrable modulus. At such a point the integral over ρ is its own finite part (Proposition 1.6): each term is $\rho^{\nu_t - 1}$ times a rational function of ρ without poles on $(0, \infty)$, the $\xi_{g,i}$ lying off $(-\infty, 0]$, whose primitive, a sum of rational functions and of logarithms $\log \rho$ and $\log(\rho + \xi_{g,i})$, has log-power expansions at both ends. Finite parts are linear, so the integral over ρ is $\sum_t A_t B_t \operatorname{Sc}_t$. A term in which no letter with $k_{t,g} > 0$ has a Skeleton value integrates $\rho^{\nu_t - 1}$, whose primitive ρ^{ν_t}/ν_t or $\log \rho$ has no constant term at either

end, so $\mathrm{Sc}_t = 0$. Otherwise, by Theorem 1.7, Sc_t is the constant term at $\kappa = \nu_t$ of the integral $\int_0^\infty \rho^{\kappa-1} \prod_{g,i} (\rho + \xi_{g,i})^{-k_{t,g}} d\rho$, continued from the strip $0 < \operatorname{Re}\kappa < |\mathbf{w}_t|$, where it converges, the product having degree $|\mathbf{w}_t| = \sum_g k_{t,g} c_g$ in ρ; on the strip it is the stacked Gamma times the Breta of the statement (Proposition 15.1, coincident Skeleton values merging), and both sides are meromorphic in κ, so their constant terms at ν_t agree.

(iv) At $c = 1$ every c_g is at most one by (i). A letter with $c_g = 1$ has the one Skeleton value $\gamma_R^g(u')/\gamma_B^g(u)$, positive (Corollary 19.5, the weights 1 factoring). Fix κ in the strip. Corollary 15.5, one coefficient ξ_g for each letter of the term with a Skeleton value, writes the stacked Gamma times the Breta as an integral over $|J_t| - 1$ shares a_ℓ on the lines $\operatorname{Re} a_\ell = c_\ell$ of a product of Beta corners in the shares and of the powers $\xi_g^{-b_g}$, $b_\ell = w_{t,\ell} - a_\ell$ for the shared coefficients and $b_0 = w_{t,0} - \kappa + |\mathbf{a}|$ for the last, affine in the shares and in κ, with $\operatorname{Re} b_g$ constant on the contour. The Beta corners are absolutely integrable over the contour: those in one share are bounded by a constant times $e^{-\pi|\operatorname{Im} a_\ell|}(1 + |\operatorname{Im} a_\ell|)^{w_{t,\ell}-1}$ by the classical bound $|\Gamma(c + i\tau)| \le C_c\, e^{-\pi|\tau|/2}(1 + |\tau|)^{c-1/2}$, and the last one by its value at the real parts of its entries, since $|\Gamma(z)| \le \Gamma(\operatorname{Re} z)$ for $\operatorname{Re} z > 0$. As $|\xi_g^{-b_g}| = \gamma_R^g(u')^{-\operatorname{Re} b_g} \gamma_B^g(u)^{\operatorname{Re} b_g}$, the integral of the modulus of $A_t B_t$ times the share integrand over the contour, Δ_{Z_B} and Δ_{Z_R} is the integral of the modulus of the share kernel times the two integrals of the statement, finite; by Fubini the integrals over Δ_{Z_B} and Δ_{Z_R} move inside the share integral, where at fixed shares the integrand is a function of u times a function of u', and they separate. If $0 < \nu_t < |\mathbf{w}_t|$, the integral over ρ of the term converges at $\kappa = \nu_t$ and is Sc_t (Proposition 1.6), and the argument runs at $\kappa = \nu_t$.

(v) By Lemma 34.11, every element of $L(H_F, \widetilde{\sigma}_\mathcal{E})$ is $[H_F, \widetilde{\sigma}_\mathcal{E}, [\eta]]^{\mathrm{mot}}$ for a regular form η on $V_F = V_{\mathcal{E};\varnothing\subsetneq\mathcal{E}}$. The step $\mathcal{E}$ meets the bunch of the root and its complement, so it is attached to the root as a node step, and (iii) applies to η. The left factors are elements of $L(H_F, \widetilde{\sigma}_\mathcal{E})$ by Definition 34.5.

(vi) At a split vertex the tables are direct sums over the molecules (Proposition 7.9), so the children at patterns of $M_v \setminus Z$ are direct sums over the parts of Z in the molecules (proof of Lemma 34.10), and $Z_B = Z \cap M_1$ is a union of molecules of each of them, of width zero (Lemma 7.10); the same holds for the duals. The list $\binom{J}{1}$ has width one at Z_B exactly when it has bases on both sides, that is when J meets Z_B and Z_R, and width zero otherwise. The proofs of (ii) to (iv) use only the widths of the letters at Z_B, here at most one. □

Lemma S18 (Families on two marks)**.** *Every convergent family F on a set $\mathcal{E}$ of two marks (Definition 34.1) has $H_F \cong \mathbb{Q}(0)$, and $P_F^{\mathrm{mot}} = P_F$, the Beta corner $\Gamma_{\!\!\begin{smallmatrix}2\\1\end{smallmatrix}}\!\left[\begin{smallmatrix}\kappa_{\{1\}}, & \kappa_{\{2\}}\\ \kappa_{\{1\}} + \kappa_{\{2\}}\end{smallmatrix}\right]$ of its walls, a positive rational number.*

Proof. The lists on $\mathcal{E} = \{1, 2\}$ have the basis polynomials 1, α_1, α_2, $\alpha_1\alpha_2$ and $\alpha_1 + \alpha_2$, and their cobasis polynomials are among these. $X_\mathcal{E}$ is the projective line, its boundary the two points $\alpha_1 = 0$ and $\alpha_2 = 0$, the monomials have no zeros on the torus, and the linear letter $\alpha_1 + \alpha_2$ is always removed; so V_F is the projective line less one point, an affine line, and D_F two points of it. In the long exact sequence of the pair, a sequence of morphisms of Brown's category (Huber and Müller-Stach), $H^0(V_F) \to H^0(D_F) \to H^1(V_F, D_F) \to H^1(V_F)$, the first map is the diagonal $\mathbb{Q}(0) \to \mathbb{Q}(0)^2$ and H^1 of the affine line is 0, every form $f(x)\,dx$ being exact; so $H_F \cong \mathbb{Q}(0)$. By the relation of Definition 34.5 for this isomorphism every motivic period of H_F is a rational multiple of the unit $[\mathbb{Q}(0), 1, 1]^{\mathrm{mot}} = 1$, the multiple being its period. On $\Delta_\mathcal{E}$ the letter $\alpha_1 + \alpha_2$ is 1 and the monomials shift the masses to the walls, so $P_F = \int_0^1 u^{\kappa_{\{1\}}-1}(1-u)^{\kappa_{\{2\}}-1} du$, with $\kappa_{\{1\}}, \kappa_{\{2\}} \ge 1$ integers. □

Theorem 34.17 (Pinned cells split off motivically). *As stated.*

Proof. Write $\mathbf{h} = \{h_1, \dots, h_q\}$ and $r_{ij} = r_{\mathcal{A}_{ij}}$, so that $K_{\mathcal{A}_{ij}/g_i}$ and $\Psi_{\mathcal{A}_{ij}\setminus g_i}$ have the degrees $r_{ij} - 1$ and $|R_i| - r_{ij}$; the core $\mathcal{H}_j$ has at least two marks, as no mark of a table on one mark is neither a loop nor a coloop, so $\mathcal{E} \setminus R_i \neq \varnothing$.

(v) is Corollary 21.11.

The walls of the cells. R_i has width one in every active table (Proposition 21.3(i)), so on the balance wall $\kappa_{R_i} + \kappa_{\mathcal{E}\setminus R_i} = \sum_j (s_j + t_j) = 2\sigma$ (Proposition 8.16); both are at least 1, F being convergent, so $1 \leq \kappa_i \leq 2\sigma - 1$.

The letters. By Theorem 21.4 and the hypothesis every active letter reads the core at one point:

$$K_j = \prod_i K_{\mathcal{A}_{ij}/g_i}(\alpha_{R_i})\, K_{\mathcal{H}_j}(\mathbf{x}), \qquad \Psi_j = \prod_i \Psi_{\mathcal{A}_{ij}\setminus g_i}(\alpha_{R_i})\, \Psi_{\mathcal{H}_j}(\mathbf{x}),$$
$$\mathbf{x} = \big(\alpha_L, \gamma_1(\alpha_{R_1}), \dots, \gamma_q(\alpha_{R_q})\big),$$

a mark of L standing at its own variable, both hinge values of $\binom{\{l,g\}}{1}$ being α_l.

The map. Each γ_i is a quotient of polynomials, homogeneous of degree one, so

$$\Phi :\ \mathbb{P}(\mathbb{Q}^{\mathcal{E}}) \dashrightarrow \mathbb{P}(\mathbb{Q}^{L\sqcup\mathbf{h}}) \times \prod_i \mathbb{P}(\mathbb{Q}^{R_i}), \qquad [\alpha] \mapsto \big([\mathbf{x}], [\alpha_{R_1}], \dots, [\alpha_{R_q}]\big),$$

is well defined, between varieties of the same dimension $|\mathcal{E}| - 1$; off the zero sets of the numerators and denominators of the γ_i it is an isomorphism between open subsets of the tori, with the inverse $\alpha_L = x_L$, $\alpha_{R_i} = \big(x_{h_i}/\gamma_i(v_i)\big)v_i$ at $([\mathbf{x}], [v_1], \dots, [v_q])$, well defined by the same homogeneity. Let U_1 be the torus less these zero sets, those of the augmented letters of F, and the preimages under Φ of those of the augmented letters of the core family and of the pinned families, and $U_2 = \Phi(U_1)$. All these polynomials are positive at the positive points, so Φ maps $\widetilde{\sigma}^\circ_{\mathcal{E}}$ onto $\widetilde{\sigma}^\circ_{L\sqcup\mathbf{h}} \times \prod_i \widetilde{\sigma}^\circ_{R_i}$.

The forms. On the positive points write $\alpha_{R_i} = \lambda_i v_i$ with $\lambda_i > 0$ and v_i on a section of the rays of $\mathbb{R}^{R_i}_{>0}$, so that $x_{h_i} = \lambda_i \gamma_i(v_i)$. In logarithmic coordinates Φ keeps $\log \alpha_L$ and the v_i and adds $\log \gamma_i(v_i)$ to $\log \lambda_i$, a map with Jacobian determinant 1; with $\nu_X = \Omega_X/\alpha^X$, the form Ω_X/α^X being the invariant volume of the logarithmic coordinates modulo $\mathbf{1}$ (proof of Lemma S15), $\Phi^*\big(\nu_{L\sqcup\mathbf{h}} \wedge \bigwedge_i \nu_{R_i}\big) = \pm\nu_{\mathcal{E}}$, an identity of rational forms since it holds at the Zariski dense positive points. The core family $F_{\mathcal{H}}$ is on its balance wall: by Proposition 21.3(i), $r_j = r_{\mathcal{H}_j} + \sum_i (r_{ij} - 1)$, and

$$m_L + \sum_i \kappa_i = m_{\mathcal{E}} - \sum_{i,j} \big(s_j(r_{ij} - 1) + t_j(|R_i| - r_{ij})\big) = \sum_j \Big(s_j r_{\mathcal{H}_j} + t_j\big(|L| + q - r_{\mathcal{H}_j}\big)\Big),$$

with $\kappa_i = m_{R_i} - \sum_j \big(s_j(r_{ij} - 1) + t_j(|R_i| - r_{ij})\big)$ (Theorem 21.10). The word of G_i is that of Corollary 22.7, $\gamma_i^{-\kappa_i} \prod_j K_{\mathcal{A}_{ij}/g_i}^{-s_j} \Psi_{\mathcal{A}_{ij}\setminus g_i}^{-t_j}$, homogeneous of the degree $-m_{R_i}$, so G_i is on its balance wall. Pulling back $\omega_{F_{\mathcal{H}}}$ and ω_{G_i} by Φ substitutes $\mathbf{x}$ and $v_i = \alpha_{R_i}$ in their coefficients, and the powers $\gamma_i(\alpha_{R_i})^{\pm\kappa_i}$ cancel:

$$\Phi^*\big(\omega_{F_{\mathcal{H}}} \boxtimes \omega_{G_1} \boxtimes \cdots \boxtimes \omega_{G_q}\big) = \pm\, \alpha^{\mathbf{m}} \prod_j K_j^{-s_j} \Psi_j^{-t_j}\, \nu_{\mathcal{E}} = \pm\, \omega_F.$$

(i) By the change of variables the period of F, of the positive integrand, is the product of the periods of $F_{\mathcal{H}}$ and of the G_i in $(0, \infty]$; this is Corollary 22.6 with Corollary 22.7. P_F is finite, so every factor is finite, and at integer data on its balance wall every proper wall of each factor is then at least 1 (Theorem 8.7): $F_{\mathcal{H}}$ and the G_i are convergent, their tables being lists.

(ii) Apply Lemma 34.7 to $(X_{\mathcal{E}}, D, Y_F)$ and to the product of the toric varieties of $F_{\mathcal{H}}$ and of the G_i with the union of the pull-backs of their boundaries and of their removed sets, a smooth projective variety with a divisor with simple normal crossings and smooth components, with the cells $\widetilde{\sigma}_{\mathcal{E}}$ and $\widetilde{\sigma}_{L\sqcup\mathbf{h}} \times \prod_i \widetilde{\sigma}_{R_i}$ and the forms ω_F and $\omega_{F_{\mathcal{H}}} \boxtimes \omega_{G_1} \boxtimes \cdots \boxtimes \omega_{G_q}$, regular on $V_{F_{\mathcal{H}}} \times \prod_i V_{G_i}$ by (i); the two periods are positive, so the signs of the orientations and of the forms match as in the proof of Corollary 34.8. With Lemma S17,

$$P_F^{\mathrm{mot}} = \Big[H^{n-1}\Big(V_{F_{\mathcal{H}}} \times \prod_i V_{G_i}, \partial\Big), \widetilde{\sigma}_{L\sqcup\mathbf{h}} \times \prod_i \widetilde{\sigma}_{R_i}, \omega_{F_{\mathcal{H}}} \boxtimes \cdots \boxtimes \omega_{G_q}\Big]^{\mathrm{mot}} = P_{F_{\mathcal{H}}}^{\mathrm{mot}} \prod_i P_{G_i}^{\mathrm{mot}},$$

and Lemma 34.6(iii) gives the conjugates.

(iii) Each cell is itself a substitution: $\mathcal{A}_{ij} = \binom{\{x,h\}}{1}\langle\binom{\{g_i,y\}}{1}, \mathcal{A}'_{ij}\rangle$, the mark g_i left in place at x and $\mathcal{A}'_{ij}$, a copy of $\mathcal{A}_{ij}$ with its hinge renamed, at h: the basis $\{h\}$ of the core contributes the bases of $\mathcal{A}_{ij} \setminus g_i$ and the basis $\{x\}$ the sets $Y + g_i$, Y a basis of $\mathcal{A}_{ij}/g_i$ (Definition 21.1). The hinge values of $\mathcal{A}'_{ij}$ are those of $\mathcal{A}_{ij}$, so the cell family F_i is read through the one hinge value γ_i, its wall at R_i is κ_i (Theorem 21.10, with the masses $\mathbf{m}|_{R_i}$), and it is on its balance wall with the mass $2\sigma - \kappa_i$ on g_i (Lemma 21.12). Its core family F'_i has the tables $\binom{\{g_i,h\}}{1}$, whose two letters are both $\alpha_{g_i} + \alpha_h$, with the masses $2\sigma - \kappa_i$ on g_i and κ_i on h, and its pinned family at the same loads is G_i. By the change of variables as in (i), in $(0,\infty]$, $P_{F_i} = P_{F'_i} P_{G_i}$ with $P_{F'_i} = \int_0^1 u^{2\sigma-\kappa_i-1}(1-u)^{\kappa_i-1}du = \Gamma\begin{bmatrix}\kappa_i, & 2\sigma-\kappa_i \\ & 2\sigma\end{bmatrix}_2^1$, finite since $1 \le \kappa_i \le 2\sigma - 1$. So P_{F_i} is finite, F_i is convergent (Theorem 8.7), and (ii) for F_i gives $P_{F_i}^{\mathrm{mot}} = P_{F'_i}^{\mathrm{mot}} P_{G_i}^{\mathrm{mot}}$, with $P_{F'_i}^{\mathrm{mot}}$ the Beta corner by Lemma S18.

(iv) The form of G_i was computed above without reference to the loads; its period is the integral over Δ_{R_i} of its coefficient, the pinned shape integral of Theorem 22.5 with all its constants 1; and two choices of loads give two convergent families on R_i with one form, hence one motivic period (Lemma 34.7). □

Corollary 34.18 (Dual pairs and full leans). *As stated.*

Proof. (a) By Proposition 21.8(ii) each cell has $\gamma^K_{\mathcal{A}_i} = \gamma^{\Psi}_{\mathcal{A}_i} = k_i/\psi_i$, so the one active table reads it through one hinge value whatever s and t, and Theorem 34.17 applies. With $K_{\mathcal{A}_i/g_i} = \Psi_{\mathcal{A}_i \setminus g_i} = \psi_i$, the form of the pinned family (Theorem 34.17(iv)) is $(k_i/\psi_i)^{-\kappa_i}\psi_i^{-s}\psi_i^{-t}\alpha^{\mathbf{m}|_{R_i}}\nu_{R_i} = k_i^{-\kappa_i}\psi_i^{-(s+t-\kappa_i)}\alpha^{\mathbf{m}|_{R_i}}\nu_{R_i}$, the form of $(\mathcal{A}_i \setminus g_i; \kappa_i, s+t-\kappa_i)$ at the masses $\mathbf{m}|_{R_i}$, and $\mathcal{A}_i \setminus g_i = \mathcal{B}|R_i$, the cell of the bunch R_i (Proposition 21.3(i), Theorem 19.4). By Proposition 21.8(i), $|R_i| - r_{\mathcal{A}_i} = r_{\mathcal{A}_i} - 1$ with $r_{\mathcal{A}_i} = r(R_i)$, so Theorem 21.10 gives $\kappa_i = m_{R_i} - (s+t)(r(R_i)-1)$. The family $(\mathcal{B}|R_i; \kappa_i, s+t-\kappa_i)$ at the masses $\mathbf{m}|_{R_i}$ has the form of the convergent pinned family, which is homogeneous of degree zero, so it is on its balance wall; its walls are the orders of the form along the boundary divisors plus one (Proposition 34.4(ii)), those of the pinned family, so it is convergent, and by Lemma 34.7 the two have one motivic period. Theorem 34.17(ii) is the display.

(b) Let $t = 0$; the case $s = 0$ is the same with Ψ. If $s = 0$ too, $\kappa_S + \kappa_{\mathcal{E}\setminus S} = 0$ for every S on the balance wall (Proposition 8.16), against convergence; so $s \neq 0$, and only K is active: every cell of every substitution of $\mathcal{B}$ is read through one hinge value, its γ^K. By Proposition 8.16, $\kappa_S + \kappa_{\mathcal{E}\setminus S} = s\,c(S) \ge 2$ for every nonempty proper S, so $\mathcal{B}$ is connected. We induct on $|\mathcal{E}|$.

If $\mathcal{B}$ has a set R of width one with $|R|, |\mathcal{E} \setminus R| \ge 2$, then $\mathcal{B} = \mathcal{H}\langle\mathcal{A}\rangle$, the marks of $L = \mathcal{E} \setminus R$ left in place, $\mathcal{H}$ the cell of the room and $\mathcal{A}$ the cell of the bunch R (Proposition 21.3(iii)), connected lists on fewer marks (Proposition 21.3(iv)). Theorem 34.17(ii),(iii) with $q = 1$ give

$$P_F^{\mathrm{mot}} = \Gamma\begin{bmatrix}\kappa_R, & s-\kappa_R \\ & s\end{bmatrix}_2^1{}^{-1} P_{(\mathcal{H};s,0)}^{\mathrm{mot}}\, P_{(\mathcal{A};s,0)}^{\mathrm{mot}},$$

the two families convergent at the masses $(\mathbf{m}|_L, \kappa_R)$ and $(\mathbf{m}|_R, s-\kappa_R)$, where $s-\kappa_R=\kappa_L$ (Proposition 8.16); the marker of each carries the wall of F at the marks on the other side of the split. A wall of $(\mathcal{H}; s, 0)$ at a set containing the marker is the wall of F at that set with the marker replaced by R, and at a set of marks of L it is the wall of F there (Theorem 21.10, the hinge g of $\mathcal{A}$ having $d_{\mathcal{A}}(R+g)=d_{\mathcal{A}}(R)+1$ and $d^*_{\mathcal{A}}(R+g)=d^*_{\mathcal{A}}(R)+1$); likewise for $(\mathcal{A}; s, 0)$. So the induction, applied to the two families, writes P_F^{mot} as a positive rational number times the product over the prime nodes of $P_{F_v}^{\mathrm{mot}}$, with the masses of the statement.

Otherwise $\mathcal{B}$ is prime, its own one node, or it has two or three marks. A connected list on two marks is $\binom{\mathcal{E}}{1}$, and one on three marks is $\binom{\mathcal{E}}{1}$ or $\binom{\mathcal{E}}{2}$, having no loop and no coloop. On two marks P_F^{mot} is a positive rational number by Lemma S18. On three marks, for a mark g, neither a loop nor a coloop, $\mathcal{B}$ is the cell $\binom{\{g,h\}}{1}\langle g, \mathcal{A}'\rangle$ of the proof of Theorem 34.17(iii) with the two other marks as R, and Theorem 34.17(ii) writes P_F^{mot} as the product of the motivic periods of a convergent family on the two marks g, h and of a convergent pinned family on the two marks of R, each a positive rational number by Lemma S18. Lemma 34.6(iii) gives the conjugates, a nonzero rational factor changing nothing. □

Theorem 34.19 (A pinned set splits off motivically). *As stated.*

Proof. F is a family of lists, so by Theorem 28.25 the active hinge values at S are equal, $\gamma=\gamma^K_{j,S}=\gamma^\Psi_{j',S}$ for all active K_j and $\Psi_{j'}$. Every active table $\mathcal{B}_j$ has width one at S with factoring weights, so it is the gluing of its cell of the bunch $\mathcal{B}^+_{j,S}$ and its cell of the room $\mathcal{B}^+_{j,S'}$ along their hinges (Proposition 21.3(iii)), that is the substitution $\mathcal{B}^+_{j,S'}\langle\mathcal{B}^+_{j,S}\rangle$ with the marks of S' left in place (Definition 21.1); the hinge values of $\mathcal{B}^+_{j,S}$ are $\gamma^K_{j,S}$ and $\gamma^\Psi_{j,S}$. So the hypothesis of Theorem 34.17 holds with $q=1$, $L=S'$, $R_1=S$ and $\gamma_1=\gamma$, $|S|\geq 2$. Its core family is $((\mathcal{B}^+_{j,S'}; s_j, t_j))_j$ at the masses $(\mathbf{m}|_{S'}, \kappa_S)$. By Proposition 28.3(ii) the room station letters of S' are $\mathsf{y}_{jD_0}=K_{\mathcal{B}_j|S'}$, $\mathsf{y}_{jD_1}=K_{\mathcal{B}_j/S}$, $\mathsf{y}^*_{jD_0}=\Psi_{\mathcal{B}_j|S'}$ and $\mathsf{y}^*_{jD_1}=\Psi_{\mathcal{B}_j/S}$, so the partner with its stand-in at $\mathbf{1}$ has the letters $K_{\mathcal{B}_j|S'}+\alpha_g K_{\mathcal{B}_j/S}$ and $\alpha_g\Psi_{\mathcal{B}_j|S'}+\Psi_{\mathcal{B}_j/S}$ and the mass κ_S on g (Theorem 28.10(i)), the letters of the cell of the room (Theorem 19.4): it is the core family. The period of the pinned family is $\int_{\Delta_S}\gamma^{-\kappa_S}u^{\mathbf{m}|_S-\mathbf{1}}\prod_j K^{-s_j}_{\mathcal{B}_j/S'}\Psi^{-t_j}_{\mathcal{B}_j|S}\,d\omega_S$ (Theorem 34.17(iv)), and by the display after Definition 28.5, with the weights factoring, this is $\int_{\Delta_S}\phi^\rho_S$: there $\gamma^\rho_S=\prod_j(\gamma^K_{j,S})^{s_j/w}(\gamma^\Psi_{j,S})^{t_j/w}=\gamma$, $w=\sum_j(s_j+t_j)$ being the sum of the exponents of the active tables, all of width one at S. Theorem 34.17(ii) is the display, and its period is $P_F=c\,P_{S'(\mathbf{1})}$. □

Proposition 34.20 (Rational data on a Kummer cover). *As stated.*

Proof. (i) $\omega_F=\alpha^{\mathbf{m}}\prod_j K_j^{-s_j}\Psi_j^{-t_j}\,\Omega_{\mathcal{E}}/\alpha^{\mathcal{E}}$, and the balance $m_{\mathcal{E}}=\sum_g\delta_g e_g$ lets the powers of α_{e_0} be distributed as displayed, each factor of degree 0. The letters and the coordinate ratios are regular units on the points of the torus in V_F, and Mm_e, Me_g are integers, so the M-th power of the function in front of $\Omega_{\mathcal{E}}/\alpha^{\mathcal{E}}$ is a regular unit there.

(ii) In the chart of an order the ratios α_e/α_{e_0} are monomials in the ε_i, and each letter is $g/\alpha_{e_n}^{\delta_g}=\prod_i\varepsilon_i^{d_g(S_i)}\widetilde{g}$ with the sector letter $\widetilde{g}$, a unit on $V_F\cap U$ (Lemma 34.3(ii), Definition 34.1). So over the chart the extension is generated by the η_i and the $\widetilde{w}_g$, and the ring $\mathcal{O}(V_F\cap U)[\eta,\widetilde{w}]$ with $\eta_i^M=\varepsilon_i$ and $\widetilde{w}_g^M=\widetilde{g}$ is the coordinate ring of a variety finite over $V_F\cap U$: the coordinatewise M-th power map in η, which is finite and flat from a smooth variety with the coordinates η, followed by an étale cover adjoining roots of units. It is smooth, hence normal, so it is the normalization over the chart, and the charts glue because the r_e, the w_g and the $\eta_i=r_{e_i}/r_{e_{i+1}}$ are expressed in one another by monomials. The preimage of $\{\varepsilon_i=0\}$ is $\{\eta_i=0\}$. By Lemma 34.3(iii), read

for rational exponents on a branch, $\omega_F = \pm \prod_i \varepsilon_i^{\kappa_{S_i}-1} \prod_g \widetilde{g}^{-e_g} d\varepsilon$, and $\varepsilon_i^{\kappa-1} d\varepsilon_i = M \eta_i^{M\kappa-1} d\eta_i$ with $\widetilde{g}^{-e_g} = \widetilde{w}_g^{-Me_g}$ gives the display. The walls lie in $\frac{1}{M}\mathbb{Z}$ and are positive, so $M\kappa_{S_i} - 1 \geq 0$, and the $\widetilde{w}_g$ are units: the form is regular.

(iii) On $\widetilde{\sigma}_{\mathcal{E}}^{\circ}$ every ratio and every letter is real and positive (Proposition 34.4(i)), so the branch with every r_e and w_g positive is defined over it, and in a chart it is $[0,\infty)^{n-1}$ in η, mapped onto $[0,\infty)^{n-1}$ in ε by the coordinatewise M-th power, a homeomorphism preserving the orientation. So $\widetilde{\sigma}_{\mathcal{E}}^{(M)}$ is compact, semialgebraic, with its boundary in $D^{(M)}$, and it is a class in $H_{n-1}(V_F^{(M)}, D^{(M)})$; the change of variables $\varepsilon = \eta^M$ carries the integral of $\omega_F^{(M)}$ over it to the integral of the principal branch of ω_F over the positive cell, which is P_F (Proposition 34.4(v)). $V_F^{(M)}$, $D^{(M)}$ and $\omega_F^{(M)}$ are defined over $\mathbb{Q}$, so $H^{n-1}(V_F^{(M)}, D^{(M)})$ is an object of the category of realizations, as in Definition 34.5. At $M = 1$ there are no roots to adjoin.

(iv) The group acts on the generators of the extension and so on the normalization, over $\mathbb{Q}(\mu_M)$. By (i), $\omega_F^{(M)} = \prod_e r_e^{Mm_e} \prod_g w_g^{-Me_g}\, \Omega_{\mathcal{E}}/\alpha^{\mathcal{E}}$ on the points over the torus, and $\Omega_{\mathcal{E}}/\alpha^{\mathcal{E}}$ is pulled back from V_F; so the pullback by (ζ,ζ') multiplies it by $\chi(\zeta,\zeta')$ there, hence everywhere, the points over the torus being dense. The action on the de Rham cohomology is by pullback, so the class lies in the χ-eigenspace. □

Theorem 34.21 (Motivic periods are separated by their conjugates). *As stated.*

Proof. (i) The category of realizations of Definition 34.5 is a Tannakian category with two fibre functors, the Betti and the de Rham realizations, and its motivic periods are the functions on the scheme P of tensor isomorphisms from the de Rham to the Betti fibre functor, its de Rham periods the functions on the group G^{dR} of tensor automorphisms of the de Rham fibre functor; the coaction is dual to the action $P \times G^{\mathrm{dR}} \to P$, $(p,g) \mapsto p \circ g$, and the period is evaluation at the comparison isomorphism $c \in P(\mathbb{C})$ (Brown's description of motivic periods, which applies because $\mathcal{P}^{\mathrm{mot}}$ and $\mathcal{P}^{\mathrm{dR}}$ are defined as the matrix coefficients $[M,\gamma,\omega]$ of the objects of that category). For $\xi \in \mathcal{P}^{\mathrm{mot}}$, $(\mathrm{per} \otimes \mathrm{id})\Delta\xi$ is the function $g \mapsto \xi(c \circ g)$ on $G^{\mathrm{dR}}_{\mathbb{C}}$, the pullback of ξ along $g \mapsto c \circ g$. Since P is a torsor under G^{dR}, this map $G^{\mathrm{dR}}_{\mathbb{C}} \to P_{\mathbb{C}}$ is an isomorphism, and its pullback is injective on $\mathcal{O}(P) \subseteq \mathcal{O}(P) \otimes \mathbb{C}$. An element $\sum_j z_j \otimes w_j$ of $\mathbb{C} \otimes_{\mathbb{Q}} \mathcal{P}^{\mathrm{dR}}$ with the w_j independent over $\mathbb{Q}$ vanishes exactly when every z_j does, that is when $\mathrm{id} \otimes \varphi$ kills it for every $\mathbb{Q}$-linear $\varphi : \mathcal{P}^{\mathrm{dR}} \to \mathbb{Q}$; and $(\mathrm{id} \otimes \varphi)(\mathrm{per} \otimes \mathrm{id})\Delta\xi = \mathrm{per}\big((\mathrm{id} \otimes \varphi)\Delta\xi\big)$, the period of an element of $\mathrm{C}(\xi)$. Conversely $\xi \in \mathrm{C}(\xi)$ (Lemma 34.6(i)), so $\xi = 0$ makes every conjugate 0.

(ii) By Definition 34.5, $\Delta P_F^{\mathrm{mot}} = \sum_i [H_F, \widetilde{\sigma}_{\mathcal{E}}, e_i]^{\mathrm{mot}} \otimes [H_F, e_i^{\vee}, \omega_F]^{\mathrm{dR}}$, and $(\mathrm{per} \otimes \varphi)$ of it is the displayed sum; (i) gives the equivalence. For $e_i \in W_k$, $k < n-1$, Theorem 34.13 places $[H_F, \widetilde{\sigma}_{\mathcal{E}}, e_i]^{\mathrm{mot}}$ in the sum over flags of dimension k of the products over their steps of the open spaces, the steps having at most $k+1$ marks and being attached as stated, and Corollary 34.15 writes the period of each element of an open space as a rational combination of values of families of lists on the step and of their derivatives in the masses, which are values of families of lists with logarithmic insertions, read on convergent data. □

50.34 Chapter 35: positive words

Theorem 35.1 (Positive coefficient jets). *As stated, at positive weights that need not be rational.*

Proof. Write $P = P_F(n\mathbf{m}; n\mathbf{s}, n\mathbf{t})$, finite and positive because its walls $n\kappa_S$ are positive (8.7), and $\mathbb{E}$ for the expectation of $U \sim \mathrm{Breta}^{\circ}(F; n\mathbf{m}; n\mathbf{s}, n\mathbf{t})$, whose density on the sim-

plex is $P^{-1}u^{n\mathbf{m}-\mathbf{1}}\prod_j K_j(u)^{-ns_j}\Psi_j(u)^{-nt_j}$, positive on the open simplex. For $v\in\mathbb{R}^k$ put $X_j=v^{\mathsf T}\partial_{\mathbf b}K_j/K_j$ and $X_j^*=v^{\mathsf T}\partial_{\mathbf b}\Psi_j/\Psi_j$. With $u_{j,T}=\mathbf b_{j,T}/\theta_{j,T}$,

$$\frac{\partial_{\mathbf b}K_j}{K_j}=\mathbb{E}_{T\sim\mathbb{P}_{j,\alpha}}[u_{j,T}],\qquad \frac{\partial_{\mathbf b}\Psi_j}{\Psi_j}=\mathbb{E}_{T\sim\mathbb{P}^*_{j,\alpha}}[u_{j,T}],$$

so $|X_j|$ and $|X_j^*|$ are at most $\beta_j=\max_T|v^{\mathsf T}u_{j,T}|$ on the whole orthant.

(i) For $|\varepsilon|\max_j\beta_j<\frac12$ the weights $\theta_{j,T}\pm\varepsilon v^{\mathsf T}\mathbf b_{j,T}=\theta_{j,T}(1\pm\varepsilon v^{\mathsf T}u_{j,T})$ are positive, and the letters of the two copies of table j are $K_j(1\pm\varepsilon X_j)$ and $\Psi_j(1\pm\varepsilon X_j^*)$. The copies have the levels of table j, each counted twice at half the exponents, so the doubled family at the masses $n\mathbf m$ has the imbalance 0 and the walls $n\kappa_S$, and its word is

$$\prod_j K_j^{-ns_j}\Psi_j^{-nt_j}\cdot B_\varepsilon,\qquad B_\varepsilon=\prod_j\bigl(1-\varepsilon^2X_j^2\bigr)^{-\frac{ns_j}{2}}\bigl(1-\varepsilon^2X_j^{*2}\bigr)^{-\frac{nt_j}{2}}.$$

Its period is therefore $P\,\mathbb{E}[B_\varepsilon(U)]$, the display of (i). For $|\varepsilon|\le\varepsilon_0<(2\max_j\beta_j)^{-1}$, B_ε is a power series in ε^2 whose coefficients are polynomials in the bounded functions X_j^2,X_j^{*2}, converging uniformly on the orthant; so $\mathbb{E}[B_\varepsilon(U)]$ is analytic in ε and expands term by term, with the coefficient $\sum_j\bigl(\frac{ns_j}{2}\mathbb{E}[X_j^2]+\frac{nt_j}{2}\mathbb{E}[X_j^{*2}]\bigr)$ of ε^2. Since $X_j^2=v^{\mathsf T}\bigl(\partial_{\mathbf b}K_j\,\partial_{\mathbf b}K_j^{\mathsf T}/K_j^2\bigr)v$, P times this coefficient is $v^{\mathsf T}\mathbf H_nv$. It is a sum of nonnegative terms. If it vanishes, then for every j with $s_j>0$, $X_j(U)=0$ almost surely; the law of U has a positive density on the open simplex, so the polynomial $\sum_T(v^{\mathsf T}\mathbf b_{j,T})\alpha^T$ vanishes on an open set, and every $v^{\mathsf T}\mathbf b_{j,T}$ is 0, the monomials of distinct bases being distinct. For $t_j>0$ the same holds with $\alpha^{\mathcal E\setminus T}$. So v is orthogonal to every direction of an active table, and $v=0$ when these span $\mathbb{R}^k$.

(ii) Write $Q=R^{\mathsf T}R$ with R real. Then

$$\operatorname{tr}(Q\mathbf H_n)=\frac n2\,P\,\mathbb{E}\Bigl[\sum_j\Bigl(s_j\frac{|R\,\partial_{\mathbf b}K_j|^2}{K_j^2}+t_j\frac{|R\,\partial_{\mathbf b}\Psi_j|^2}{\Psi_j^2}\Bigr)(U)\Bigr],$$

a sum of nonnegative terms, which vanishes exactly when, as in (i), $R\mathbf b_{j,T}=0$, that is $\mathbf b_{j,T}^{\mathsf T}Q\mathbf b_{j,T}=0$, for every basis of every active table. If $Q_{11}>0$, then $Q-Q_{11}^{-1}Q_{\cdot1}Q_{\cdot1}^{\mathsf T}$ is rational, positive semidefinite, with first row and column zero; if $Q_{11}=0$, the first row and column of Q vanish, Q being positive semidefinite. Induction on k gives $Q=\sum_l c_lv_lv_l^{\mathsf T}$ with rational $c_l>0$ and rational v_l, and then $\operatorname{tr}(Q\mathbf H_n)=\sum_l c_l\,v_l^{\mathsf T}\mathbf H_nv_l$.

(iii) $\partial_{\mathbf b}K_j^{\mathsf T}Q\,\partial_{\mathbf b}K_j/K_j^2=\sum_{T,T'}\mathbf b_{j,T}^{\mathsf T}Q\,\mathbf b_{j,T'}\,\alpha^{\mathbf 1_T+\mathbf 1_{T'}}K_j^{-2}$, and $P\,\mathbb{E}\bigl[(\alpha^{\mathbf 1_T+\mathbf 1_{T'}}K_j^{-2})(U)\bigr]$ is the period whose integrand is that of P times $u^{\mathbf 1_T+\mathbf 1_{T'}}K_j(u)^{-2}$, the period at $\bigl(n\mathbf m+\mathbf 1_T+\mathbf 1_{T'};n\mathbf s+2\mathbf e_j,n\mathbf t\bigr)$. Its imbalance is that of $(n\mathbf m;n\mathbf s,n\mathbf t)$ plus $2r_j-2r_j=0$, and its wall of S is $n\kappa_S+|T\cap S|+|T'\cap S|-2d_j(S)\ge n\kappa_S$, by 7.13. The cobasis part is the same with $u^{\mathbf 1_{\mathcal E\setminus T}+\mathbf 1_{\mathcal E\setminus T'}}\Psi_j^{-2}$ and the change $|S\setminus T|+|S\setminus T'|-2d_j^*(S)\ge0$. This is the case of order two of 27.9 for the doubled family, the two copies of each table merged.

(iv) $x\mapsto x^{\mathsf T}Qx$ is convex, so $\bigl(\mathbb{E}_T[u_{j,T}]\bigr)^{\mathsf T}Q\,\mathbb{E}_T[u_{j,T}]\le\mathbb{E}_T\bigl[u_{j,T}^{\mathsf T}Qu_{j,T}\bigr]\le\max_T u_{j,T}^{\mathsf T}Qu_{j,T}$ under either law, and $\operatorname{tr}(Q\mathbf H_n)\le\frac n2P\sum_j(s_j+t_j)\max_T\mathbf b_{j,T}^{\mathsf T}Q\,\mathbf b_{j,T}/\theta_{j,T}^2=n\,C(Q)\,P$; positivity is (ii).

(v) With the basis weights $\theta^K_{j,T}$ and the cobasis weights $\theta^\Psi_{j,T}$ of every table independent (8.1), $\partial^2K_j^{-ns_j}/\partial\theta^K_{j,T}\partial\theta^K_{j,T'}=ns_j(ns_j+1)K_j^{-ns_j-2}\alpha^T\alpha^{T'}$. The differentiated integrals are the periods of (iii), convergent locally uniformly in the weights, so differentiation under the integral gives

$$\sum_{T,T'}\mathbf b_{j,T}\mathbf b_{j,T'}^{\mathsf T}\,\frac{\partial^2P}{\partial\theta^K_{j,T}\partial\theta^K_{j,T'}}=ns_j(ns_j+1)\,P\,\mathbb{E}\Bigl[\frac{\partial_{\mathbf b}K_j\,\partial_{\mathbf b}K_j^{\mathsf T}}{K_j^2}(U)\Bigr],$$

which is $2(ns_j+1)$ times the part $\frac{n}{2}s_jP\,\mathbb{E}[\cdots]$ of $\mathbf{H}_n$ carried by K_j; the cobasis part is the same with t_j. On the share side of 18.16 the weights enter only through $\prod_{j,T}(\theta^K_{j,T})^{-a_{j,T}}(\theta^\Psi_{j,T})^{-b_{j,T}}$: a derivative in $\theta^K_{j,T}$ multiplies the integrand by $-a_{j,T}/\theta^K_{j,T}$, one in $\theta^\Psi_{j,T}$ by $-b_{j,T}/\theta^\Psi_{j,T}$, and neither the contour, nor the pins, nor the share kernels involve the weights.

(vi) At the centre the two copies of table j carry the equal exponents $(\frac{ns_j}{2},\frac{ns_j}{2})$, and the masses $n\sigma\mathbf{1}$ are the total strength of the doubled family times $\mathbf{1}$. 8.21(i) holds at every family at its centre, whatever its weights: at $\mathbf{1}$ the usage is $\sum_j\sigma_j(R_j+R^*_j)(\mathbf{1})=\sigma\mathbf{1}$, since $R_{j,e}(\mathbf{1})+R^*_{j,e}(\mathbf{1})$ is the chance that e lies in the basis plus the chance that it does not. □

Remark. No step uses the rationality of the weights; rational weights are what the arithmetic of the jets asks for, through the rows of the periods of (iii).

Theorem 35.3 (Two bases generate positive contrast words of any depth). *As stated, at every point of the balance wall with real data and positive proper walls, and at positive weights.*

Proof. Write $P_n=P_F(n\mathbf{m};n\mathbf{s},n\mathbf{t})$, finite and positive (8.7), $\mathbb{E}$ for the expectation of $U\sim\mathrm{Breta}^\circ(F;n\mathbf{m};n\mathbf{s},n\mathbf{t})$, and $c=\mathbb{P}_{j,\alpha}(T)-\mathbb{P}_{j,\alpha}(T')$, $c^*=\mathbb{P}^*_{j,\alpha}(T)-\mathbb{P}^*_{j,\alpha}(T')$. Each chance lies in $(0,1)$ and two chances of distinct bases sum to at most one, so $|c|,|c^*|<1$ on the open orthant. c vanishes only where $\theta_{j,T}\alpha^{\mathbf{1}_T}=\theta_{j,T'}\alpha^{\mathbf{1}_{T'}}$, a hypersurface, since $\mathbf{1}_T\neq\mathbf{1}_{T'}$; so $c^{2h}>0$ almost everywhere, and the contrast word, $\frac12P_n$ times the expectation of a function that is positive almost everywhere under a law with a positive density, is positive.

(i) $c^{2h}=\sum_{l=0}^{2h}(-1)^l\binom{2h}{l}\theta^{2h-l}_{j,T}\theta^l_{j,T'}\,\alpha^{v_l}K_j^{-2h}$ with $v_l=(2h-l)\mathbf{1}_T+l\mathbf{1}_{T'}$, each term homogeneous of degree 0, and $P_n\,\mathbb{E}\big[(\alpha^{v_l}K_j^{-2h})(U)\big]$ is the period whose integrand is that of P_n times $u^{v_l}K_j(u)^{-2h}$, the period at $\big(n\mathbf{m}+v_l;n\mathbf{s}+2h\mathbf{e}_j,n\mathbf{t}\big)$. Its imbalance changes by $|v_l|-2hr_j=0$, and its wall of S by $(2h-l)|T\cap S|+l|T'\cap S|-2hd_j(S)\geq0$ (7.13). The second half is the same with $\mathbb{P}^*_{j,\alpha}(T)=\theta_{j,T}\alpha^{\mathcal{E}\setminus T}/\Psi_j$, the masses raised by $(2h-l)\mathbf{1}_{\mathcal{E}\setminus T}+l\mathbf{1}_{\mathcal{E}\setminus T'}$, the cobasis exponent by $2h$, and the wall of S by $(2h-l)|S\setminus T|+l|S\setminus T'|-2hd^*_j(S)\geq0$.

From $\Psi_j(\alpha)=\alpha^{\mathbf{1}}K_j(\alpha^{-1})$, $K_j(\alpha^{-1})=\alpha^{-\mathbf{1}}\Psi_j(\alpha)$ and $\Psi_j(\alpha^{-1})=\alpha^{-\mathbf{1}}K_j(\alpha)$, so $\mathbb{P}^*_{j,\alpha^{-1}}(T)=\mathbb{P}_{j,\alpha}(T)$. On the chart $y_g=0$ of 8.7 the integrand of a period at data $(\mathbf{m}';\mathbf{s}',\mathbf{t}')$ is $e^{\langle\mathbf{m}',y\rangle}\prod_j K_j(e^y)^{-s'_j}\Psi_j(e^y)^{-t'_j}$, and $y\mapsto-y$, which keeps dy, carries it to $e^{\langle2\sigma'\mathbf{1}-\mathbf{m}',y\rangle}\prod_j K_j(e^y)^{-t'_j}\Psi_j(e^y)^{-s'_j}$, σ' the total strength of $(\mathbf{s}',\mathbf{t}')$. Applied to the second half at $(n\mathbf{m};n\mathbf{s},n\mathbf{t})$ it gives the first half at $\big(n(2\sigma\mathbf{1}-\mathbf{m});n\mathbf{t},n\mathbf{s}\big)$, the depth n of the data $(2\sigma\mathbf{1}-\mathbf{m};\mathbf{t},\mathbf{s})$ of 8.14, whose wall of S is the wall of $\mathcal{E}\setminus S$ at $(\mathbf{m};\mathbf{s},\mathbf{t})$, positive. At the centre these data are $(\mathbf{m};\mathbf{s},\mathbf{t})$ themselves, and the two halves are equal.

(ii) By 17.1, with $X(z)=2\langle\boldsymbol{\mu}_\perp,z\rangle-\Phi^\circ(z)$ read on $\mathbf{1}^\perp$ and the number of marks written $|\mathcal{E}|$, $P_n=2^{|\mathcal{E}|-1}\int_{\mathcal{T}}e^{nX}dz$ and the contrast word is $2^{|\mathcal{E}|-2}\int_{\mathcal{T}}e^{nX}\big(c^{2h}+c^{*2h}\big)dz$, with c,c^* at $\alpha=e^{2z}$. For $h=\eta n$ put $\psi=-X-2\eta\log\max(|c|,|c^*|)$, with values in $(-\infty,\infty]$, continuous where finite and lower semicontinuous; then $e^{-n\psi}\leq e^{nX}(c^{2h}+c^{*2h})\leq2e^{-n\psi}$. By 17.4(i) and (ii), $-X(z)\geq2\kappa_{\min}(\max_e z_e-\min_e z_e)-C$, and the logarithmic term is nonnegative, so ψ grows at least linearly on $\mathbf{1}^\perp$. Laplace's principle follows: outside a large ball the integral of $e^{-n\psi}$ is at most $e^{-n(\inf\psi+1)}$ for large n, inside it is at most $e^{-n\inf\psi}$ times the volume, and near a point z_0 with $\psi(z_0)<\inf\psi+\epsilon$ the integrand is at least $e^{-n(\inf\psi+2\epsilon)}$ on a ball. So $\frac1n\log$ of the contrast word tends to $-\inf\psi$, and the same with $\eta=0$ and without the contrasts gives $\frac1n\log P_n\to\max X=-\min(\Phi^\circ-2\langle\boldsymbol{\mu}_\perp,\cdot\rangle)$, the maximum attained, X being continuous and tending to $-\infty$. The set $K=\{z\in\mathbf{1}^\perp:\ 2\kappa_{\min}(\max_e z_e-\min_e z_e)-C\leq\inf\psi+1\}$ is compact and contains every z with $\psi(z)\leq\inf\psi+1$; on it $\max(|c|,|c^*|)\leq1-\delta_K<1$, so $\inf\psi\geq\min(-X)+2\eta|\log(1-\delta_K)|>\min(-X)$.

For $A>0$ let B_A be a ball of $\mathbf{1}^{\perp}$ outside which $2\kappa_{\min}(\max_e z_e-\min_e z_e)-C\ge A$; on B_A, $\psi\ge\min(-X)+2\eta|\log(1-\delta_{B_A})|$, which exceeds A for large η, so $\inf\psi\ge A$ for large η.

(iii) Let $s_j>0$ and $q=2h$. In the share form of P_F used by 18.16, the letter $K_j^{-ns_j-q}$ of the term l of (i) is opened by one share a'_U per basis, $\sum_U a'_U=ns_j+q$, with the share kernel $\prod_U\Gamma(a'_U)/\Gamma(ns_j+q)$ and the factors $(\theta_{j,U}\alpha^{\mathbf{1}_U})^{-a'_U}$ (4.4). The insertion $\theta_{j,T}^{q-l}\theta_{j,T'}^{l}\alpha^{v_l}$ turns the factors of T and T' into $(\theta_{j,T}\alpha^{\mathbf{1}_T})^{-a_T}$ and $(\theta_{j,T'}\alpha^{\mathbf{1}_{T'}})^{-a_{T'}}$ with $a_T=a'_T-q+l$, $a_{T'}=a'_{T'}-l$, the other shares unchanged as $a_U=a'_U$. In the shares a the total is ns_j and the factors in α and in the weights are those of $P_F(n\mathbf{m};n\mathbf{s},n\mathbf{t})$, so the integral over α, which produces the pins, gives the pins of $(n\mathbf{m};n\mathbf{s},n\mathbf{t})$, and the kernel is

$$\frac{\Gamma(a_T+q-l)\,\Gamma(a_{T'}+l)\prod_{U\neq T,T'}\Gamma(a_U)}{\Gamma(ns_j+q)}=\frac{\prod_U\Gamma(a_U)}{\Gamma(ns_j)}\cdot\frac{(a_T)_{q-l}\,(a_{T'})_l}{(ns_j)_q}.$$

The factor $\Gamma(a_T+q-l)\Gamma(a_{T'}+l)$ is holomorphic for $\operatorname{Re}a_T>-(q-l)$ and $\operatorname{Re}a_{T'}>-l$, so the contour returns to a wall contour of $(n\mathbf{m};n\mathbf{s},n\mathbf{t})$ without crossing a pole, the share kernels decaying along the imaginary directions. Summing over l with the weights $\frac12(-1)^l\binom{q}{l}$ gives the share side of $P_F(n\mathbf{m};n\mathbf{s},n\mathbf{t})$ with the insertion $H_q(a_{j,T},a_{j,T'})/\big(2(ns_j)_q\big)$. For $t_j>0$ the second half is the same with Ψ_j, the cobasis shares b and nt_j. The insertions are polynomials in the shares and change neither the pins nor the share kernels, hence no pole hyperplane. At the centre the two halves are equal by (i), and their insertions add to the one of the reference. □

Theorem 35.14 (A positive sequence of Beta ports on an interval of a selected mark). *As stated, at every mass $m_e\in(0,1]$.*

Proof. In x, $d\alpha_e=(\lambda_1-\lambda_0)\,dx$, and the constant goes into the room density. The factor of the mass is $\alpha_e^{m_e-1}=L_0^{-(1-m_e)}$ with $L_0=\lambda_0+(\lambda_1-\lambda_0)x$, a linear letter with $c_0=\lambda_0$, $d_0=\lambda_1-\lambda_0>0$ and the exponent $w_0=1-m_e\ge0$; it satisfies $c_0\ge\lambda_0d_0/(\lambda_1-\lambda_0)$ with equality, so the read is $\langle\cdot\rangle_{1,1;\mathbf{w}}$ over the letters of the chart and L_0. For a letter with $d_i>0$ put $\mu=\lambda_0/(\lambda_1-\lambda_0)$; then $x(1-x)d_i/L_i\le x(1-x)/(\mu+x)$, whose derivative vanishes on $[0,1]$ only where $x^2+2\mu x-\mu=0$, at $x=\sqrt{\mu(1+\mu)}-\mu$, with the value $\big(\sqrt{1+\mu}-\sqrt{\mu}\big)^2=(\sqrt{\lambda_1}-\sqrt{\lambda_0})^2/(\lambda_1-\lambda_0)=\varepsilon_{01}$, the ratio of the statement; for $d_i=0$ the quotient is 0. By 35.12(i) at $a=b=1$,

$$\big\langle(-1)^n\Pi_n^{1,1}\big\rangle_{1,1;\mathbf{w}}=\sum_{|v|=n}\prod_i\frac{(w_i)_{v_i}}{v_i!}\Big\langle\prod_i\Big(\frac{x(1-x)d_i}{L_i}\Big)^{v_i}\Big\rangle_{1,1;\mathbf{w}},$$

every term between 0 and $\prod_i\frac{(w_i)_{v_i}}{v_i!}\varepsilon_{01}^n\langle1\rangle_{1,1;\mathbf{w}}$, and $\sum_{|v|=n}\prod_i(w_i)_{v_i}/v_i!=(|\mathbf{w}|)_n/n!$ by the Vandermonde identity for rising factorials. A letter L_i that sees the mark makes the term $v=n\mathbf{e}_i$ positive (35.12(ii) with $J=\{i\}$), and for $n=0$ the read is $\langle1\rangle_{1,1;\mathbf{w}}>0$. When $m_e<1$, $w_0d_0=(1-m_e)(\lambda_1-\lambda_0)>0$: the letter of the mass sees the mark. □

Theorem 35.15 (The finite-band recurrence in the order of the Beta ports). *As stated, at every pair (a_n,b_n) with $a_n,b_n>0$.*

Proof. Write $a=a_n$, $b=b_n$, $w_i=w_i(n)$. The letters are at least $\min_i c_i>0$ on $[0,1]$, so every read of a polynomial converges and the flux $x^a(1-x)^bA\prod_iL_i^{-w_i}$ of a polynomial A vanishes at both ends. 35.10(a) with the polynomial Lg reads, by $x(1-x)\partial_x(Lg)=x(1-x)(L\partial_xg+g\partial_xL)$ and $\partial_x\log L_i=d_i/L_i$,

$$x(1-x)\partial_x(Lg)+\big(a-(a+b)x\big)Lg-x(1-x)Lg\sum_i\frac{w_id_i}{L_i}=L\,x(1-x)\,\partial_xg+A_ng.$$

The coefficient of x^q in $\Pi_q^{a,b}$ is $\binom{a+b+2q-2}{q}$, a product of the q positive numbers $a+b+q-1,\dots,a+b+2q-2$ over $q!$, so $\Pi_0^{a,b},\dots,\Pi_N^{a,b}$ are a basis of the polynomials of degree at most N, and the conditions $a+b+2q-i\neq 0$ of 3.15(v) hold. By its finite rules, multiplication by x maps $\Pi_q^{a,b}$ into the span of $\Pi_{q-1}^{a,b},\Pi_q^{a,b},\Pi_{q+1}^{a,b}$, and $x(1-x)\partial_x$ maps it into the span of $\Pi_{q-1}^{a,b},\Pi_q^{a,b}$ and $x\Pi_q^{a,b}$, with coefficients rational in (a,b,q); for $q=0$, $x\Pi_0^{a,b}=x$ and $\partial_x\Pi_0^{a,b}=0$. So multiplication by a polynomial of degree d moves $\Pi_q^{a,b}$ into the span of $\Pi_{q-d}^{a,b},\dots,\Pi_{q+d}^{a,b}$. L has degree h and A_n degree at most $h+1$, so at $g=(-1)^r\Pi_r^{a,b}$,

$$L\,x(1-x)\,\partial_x g + A_n g = \sum_{s=-h-1}^{h+1} e_s\,\Pi_{r+s}^{a,b},$$

$e_s=0$ when $r+s<0$, with e_s rational in (a,b,r) and polynomial in the coefficients of L and of A_n, hence in the room data and the w_i; the mark relation is the displayed relation with $\mathfrak{b}_{n,r,s}=(-1)^{r+s}e_s$.

$\Pi_{r+h+1}^{a,b}$ is the only member of the expansion of degree $r+h+1$, so e_{h+1} is the coefficient of x^{r+h+1} divided by $\binom{a+b+2r+2h}{r+h+1}$. The coefficient of x^r in g is $(-1)^r\binom{a+b+2r-2}{r}$. The coefficient of x^{h+1} in A_n is $-(a+b)p_h-hp_h+|\mathbf{w}(n)|\,p_h$, the last from $-x(1-x)\sum_i w_i d_i\prod_{i'\neq i}L_{i'}$, whose leading coefficient is $\sum_i w_i d_i\prod_{i'\neq i}d_{i'}=|\mathbf{w}(n)|\,p_h$; and the coefficient of x^{r+h+1} in $L\,x(1-x)\,\partial_x x^r$ is $-rp_h$. So the coefficient of x^{r+h+1} is $(-1)^r\binom{a+b+2r-2}{r}\,p_h\big(|\mathbf{w}(n)|-a-b-h-r\big)$, and $\mathfrak{b}_{n,r,h+1}=(-1)^{r+h+1}e_{h+1}$ is the stated value. □

At $a_n=b_n=n+1$ the furthest coefficient is

$$\big[|\mathbf{w}(n)|-2n-2-h-r\big]\,p_h\,(-1)^{h+1}\binom{2n+2r}{r}\Big/\binom{2n+2r+2h+2}{r+h+1},$$

that of the reference.

50.35 Chapter 36: the critical-line law

Proposition 36.7 (Binomial moments of the critical-line law). *As stated.*

Proof. (i) The density $p_{\mathrm{crit}}(y)=2\pi/(e^{\pi y}+e^{-\pi y})^2$ is at most $2\pi e^{-2\pi|y|}$, so $\mathbb{E}[e^{tX}]=e^{t/2}\mathbb{E}[e^{itY}]$ is holomorphic in t on the strip $|\operatorname{Im}t|<2\pi$, as is $te^t/(e^t-1)$, whose poles $2\pi ik$, $k\neq 0$, lie outside it; they agree for real t (36.2(iii)), hence on the strip. For $|z|<1$, $t=\log(1+z)$ has $|\operatorname{Im}t|<\frac{\pi}{2}$, and $te^t/(e^t-1)=(1+z)\log(1+z)/z$.

(ii) $|\binom{x}{i}|\le\binom{|x|+i-1}{i}$ termwise, and $\sum_i\binom{|x|+i-1}{i}|z|^i=(1-|z|)^{-|x|}$. For $|z|<1-e^{-2\pi}$, $(1-|z|)^{-|X|}\le e^{c(\frac12+|Y|)}$ with $c=-\log(1-|z|)<2\pi$, which has a finite expectation, so $\mathbb{E}[(1+z)^X]=\sum_i\mathbb{E}[\binom{X}{i}]z^i$ there. The expansion $\log(1+z)/z=\sum_{i\ge0}(-1)^i z^i/(i+1)$ times $1+z$ has the coefficient 1 at $i=0$ and $(-1)^i\big(\frac{1}{i+1}-\frac{1}{i}\big)=\frac{(-1)^{i+1}}{i(i+1)}$ at $i\ge1$.

(iii) Differentiating $(1+z)^u=\sum_i\binom{u}{i}z^i$ in u gives $\log(1+z)(1+z)^u=\sum_i\frac{d}{du}\binom{u}{i}z^i$, so $\frac{d}{du}\binom{u}{i}=\sum_{m=1}^{i}\frac{(-1)^{m-1}}{m}\binom{u}{i-m}$, an identity of polynomials. By (ii), $\mathbb{E}[\frac{d}{du}\binom{u}{i}|_X]$ is the coefficient of z^i in $\log(1+z)\cdot(1+z)\log(1+z)/z$. From $\frac{d}{dz}\log^2(1+z)=2\log(1+z)/(1+z)=2\sum_{n\ge1}(-1)^{n-1}H_n z^n$, $\log^2(1+z)=2\sum_{n\ge2}(-1)^nH_{n-1}z^n/n$, and the coefficient of z^i in $(1+z)\log^2(1+z)/z$ is

$$2(-1)^{i+1}\frac{H_i}{i+1}+2(-1)^i\frac{H_{i-1}}{i}=2(-1)^i\Big(\frac{H_{i-1}}{i}-\frac{H_{i-1}+\frac1i}{i+1}\Big)=2(-1)^i\frac{H_{i-1}-1}{i(i+1)}.$$

By 36.4 at $k=1$, for $R=(1-2u)Q$, $R(\frac12)=0$ and $\mathrm{crit}_1[R]=\mathbb{E}[Q'(X)]$, which is the sum. $\square$

Proposition 36.11 (Poles at the half-integers). *As stated.*

Proof. Put $S(u)=\sum_m (u+m)^{-(2k+1)}$. From $\Gamma_{\substack{4\\0}}\big[u,\ u,\ 1-u,\ 1-u\big]=\sum_m (u+m)^{-2}$ (5.16), $\partial_u^{2k-1}\Gamma_{\substack{4\\0}}\big[u,\ u,\ 1-u,\ 1-u\big]=-(2k)!\,S(u)$, so $\mathrm{crit}_k[R]=\frac{2}{2\pi i}\int_{(1/2)} R(u)S(u)\,du/(1-2u)$. S has the period 1, poles of order $2k+1$ at the integers, it decays exponentially as $|\operatorname{Im} u|\to\infty$ uniformly in $\operatorname{Re} u$, and $S(1-u)=-S(u)$, so $S(\frac12)=0$.

For $p\notin\mathbb{Z}$ with $\operatorname{Re} p>\frac12$ let $I(p)=\frac{1}{2\pi i}\int_{(1/2)} S(u)\,du/(u-p)$. Move the line to $\operatorname{Re} u=N+\frac12$: the horizontal segments vanish by the decay of S, and on the new line $|1/(u-p)|\le 1/(N+\frac12-\operatorname{Re} p)\to 0$ while $\int|S|$ there is that on $\operatorname{Re} u=\frac12$. So $I(p)$ is minus the sum of the residues to the right of the line: at $u=p$ the residue $S(p)$, and at an integer $i\ge 1$ the residue of $(u-i)^{-2k-1}/(u-p)$, which is $(i-p)^{-2k-1}$. At $p=\frac12+l$, $l\ge 1$, $S(p)=\sum_{x\in\frac12+\mathbb{Z}} x^{-2k-1}=0$, and

$$I(p)=-\sum_{i\ge1}\big(i-\tfrac12-l\big)^{-2k-1}=-\sum_{x\in\frac12+\mathbb{Z},\ x>l} x^{-2k-1}=-(\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((l,\infty)),$$

the points x with $|x|<l$ cancelling in pairs. At $l=0$ the integrand $S(u)/(u-\frac12)$ is regular on the line; for real $p=\frac12+\varepsilon$, $\varepsilon\downarrow 0$, $|S(u)/(u-p)|\le|S(u)/(u-\frac12)|$ on the line, an integrable function, so the integral is $\lim I(p)=-S(\frac12)-\sum_{i\ge1}(i-\frac12)^{-2k-1}=-(\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,\infty))$.

For the word, $\frac{1}{(u-p)(1-2u)}=\frac{1}{1-2p}\big(\frac{1}{u-p}-\frac{1}{u-\frac12}\big)$, so at $p=\frac12+l$

$$\begin{aligned}\mathrm{crit}_k\left[\frac{1}{u-p}\right]&=\frac{2}{1-2p}\Big((\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,\infty))-(\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((l,\infty))\Big)\\&=-\frac{1}{l}\,(\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,l])\end{aligned}$$

by the cut relation (5.3). Finally $u\mapsto 1-u$ maps the line onto itself, reversing it, and with $S(1-u)=-S(u)$ it gives $\mathrm{crit}_k[R(1-u)]=\mathrm{crit}_k[R(u)]$; for $R(u)=1/(u-\frac12+l)$, $R(1-u)=-1/(u-\frac12-l)$. $\square$

50.36 Chapter 37: the gap and the shape words

Proposition 37.8 (The root rate of the shape words). *As stated, with the maximizer at every $k\ge 2$.*

Proof. (i), the limit in (ii) and the last sentence are the reference's (the reference, proof of prop:kdepth). For the maximum, fix $x_1,\dots,x_k$ and put $y=x_1\cdots x_k$. The factor of f_k in x_0 is $x_0(1-x_0)/\big(1-(1-y)x_0\big)$; its derivative vanishes where $1-2x_0+(1-y)x_0^2=0$, at $x_0=1/(1+\sqrt{y})$, where $1-x_0=\sqrt{y}/(1+\sqrt{y})$ and $1-(1-y)x_0=\sqrt{y}$, with the value $(1+\sqrt{y})^{-2}$. So $M_k(0)=\sup\prod_{i\ge1}x_i(1-x_i)\big/\big(1+\sqrt{x_1\cdots x_k}\big)^2$. At a fixed product the numerator is largest when the x_i are equal, $t\mapsto\log(1-e^t)$ being concave, so $M_k(0)=\max_{0<a<1}\phi(a)$ with $\phi(a)=a^k(1-a)^k/(1+a^{k/2})^2$, and

$$\frac{\phi'(a)}{\phi(a)}=k\Big(\frac{1}{a}-\frac{1}{1-a}-\frac{a^{k/2-1}}{1+a^{k/2}}\Big)=\frac{k\left(1-2a-a^{k/2+1}\right)}{a(1-a)(1+a^{k/2})}.$$

The numerator decreases strictly from 1 at $a = 0$ to $-2^{-k/2-1}$ at $a = \frac{1}{2}$, so ϕ increases up to the unique root $a \in (0, \frac{1}{2})$ of $a^{k/2+1} + 2a = 1$ and decreases after it. At $\eta = 0$ the equation of 37.7 is $(1-2a)^2 = a^{k+2}$, whose root in $(0, \frac{1}{2})$ solves $1 - 2a = a^{k/2+1}$: the same a, with $x_2 = \cdots = x_k = a$ and $x_0 = a/(1-a) = 1/(1+a^{k/2})$, since $a^{k/2} = (1-2a)/a$. The interval follows from $\phi(\frac{1}{2}) \le M_k(0) \le 4^{-k}$. At $k = 2$ the root is $\sqrt{2} - 1$ and at $k = 4$ the root of $a^3 + 2a - 1$, the maximizers of the reference. □

Proposition 37.14 (The insertion index supplies auxiliary states). *As stated, for every $k \ge 3$.*

Proof. By 37.13(ii), which holds for every $k \ge 2$, the share function of P_r is

$$g_{n,r}(a) = \binom{n+r}{r} \frac{(n!)^{k-2}\,(1-a)_n^2\,(n+1-a)_r}{(a)_{n+1}^k\,(n+1+a)_r}.$$

Its poles in $a \le 0$ are at $a = -h$, $0 \le h \le n$, of order exactly k, the numerator being nonzero there, and at $a = -h$, $n < h \le n + r$, simple. For $k \ge 3$ the coefficients of order $k - 1 \ge 2$ come from the first poles only, so $C_{n,k}(P_r) = \sum_{h=0}^{n} R_h(-h)$ and $C_{n,k-1}(P_r) = \sum_{h=0}^{n} R_h'(-h)$, with $R_h(a) = (a+h)^k g_{n,r}(a)$, holomorphic near $-h$. First,

$$R_h(-h) = \binom{n+r}{r} \frac{(n!)^{k-2}(1+h)_n^2}{\prod_{j\ne h}(j-h)^k} \cdot \frac{(n+1+h)_r}{(n+1-h)_r}, \qquad \frac{(n+1+h)_r}{(n+1-h)_r} = \frac{(n+1-h+r)_{2h}}{(n+1-h)_{2h}},$$

the product over $0 \le j \le n$; $\binom{n+r}{r} = (r+1)_n/n!$ and $(n+1-h+r)_{2h}$ are polynomials in r, $n + 1 - h \ge 1$, so $R_h(-h) \in \mathbb{Q}[r]$ and $C_{n,k}(P_r) \in \mathbb{Q}[r]$. Second, $R_h'(-h) = R_h(-h)\,\rho_h$ with

$$\rho_h = -2\sum_{i=1}^{n} \frac{1}{i+h} - \sum_{i=n+1}^{n+r} \Big(\frac{1}{i+h} + \frac{1}{i-h}\Big) - k\sum_{j\ne h} \frac{1}{j-h},$$

the logarithmic derivatives at $-h$ of $(1-a)_n^2$, $(n+1-a)_r$, $(n+1+a)_r^{-1}$ and $\prod_{j\ne h}(a+j)^{-k}$. The finite Trailmoment $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,N])$ is the sum of m^{-1} over $0 < m \le N$, so $\sum_{i=n+1}^{n+r} \frac{1}{i+h} = (\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+r]) - (\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+h]) + \sum_{i=1}^{h} \frac{1}{n+r+i}$ and $\sum_{i=n+1}^{n+r} \frac{1}{i-h} = (\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+r]) - (\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n-h]) - \sum_{i=0}^{h-1} \frac{1}{n+r-i}$, and $\rho_h = -2\,(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+r]) + \tilde{\rho}_h(r)$ with $\tilde{\rho}_h \in \mathbb{Q}(r)$. Summing, $C_{n,k-1}(P_r) = -2\,(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+r])\,C_{n,k}(P_r) + q_n(r)$ with $q_n = \sum_h R_h(-h)\tilde{\rho}_h \in \mathbb{Q}(r)$.

Let $\sum_{i=0}^{d} b_i(r)\,C_{n,k-1}(P_{r+i}) = 0$ for all large r, $b_i \in \mathbb{Q}(r)$. Since $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+r+i]) = (\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+r]) + \sum_{l=1}^{i} \frac{1}{n+r+l}$, this reads $A(r)\,(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+r]) + B(r) = 0$ for all large r with $A = -2\sum_i b_i(r) C_{n,k}(P_{r+i})$ and B in $\mathbb{Q}(r)$. If $A \ne 0$, then $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+r]) = -B(r)/A(r)$ for all large r; a rational function is asymptotic to cr^e with $e \in \mathbb{Z}$, while $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+r]) - \log r$ has a limit, which is impossible. So $A = 0$: the recurrence annihilates $C_{n,k}(P_r)$. □

Theorem 37.19 (An arithmetic budget for growing Beta ports). *As stated, with the coefficient of the top coordinate at every $k \ge 2$.*

Proof. The two limits and the clearing are the reference's (the reference, proof of thm:portbudget). The coefficient of $(\mathsf{T}_{k+1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ in $I_n(k;P)$ is $k\,C_{n,k}(P)$ (37.4(iii)), and $P =$

$(-1)^q \Pi_q^{n+1,n+1}(x_1)$ is free of x_0, so the theorem applies. As in the proof of 37.14, at $r = q$, $C_{n,k}(P) = \sum_{h=0}^{n} R_h(-h)$ with $\prod_{j \neq h}(j-h) = (-1)^h h!\,(n-h)!$ and $(1+h)_n = (n+h)!/h!$:

$$R_h(-h) = \binom{n+q}{q} \frac{(n!)^{k-2}}{(h!(n-h)!)^k} \frac{((n+h)!)^2}{(h!)^2} (-1)^{hk} \frac{(n+1+h)_q}{(n+1-h)_q}$$
$$= \binom{n+q}{q} (-1)^{hk} \binom{n}{h}^k \binom{n+h}{n}^2 \frac{(n+1+h)_q}{(n+1-h)_q}.$$

For even k every term is positive. □

Corollary 37.20 (A growing Beta port with a certified gap). *As stated, for every $k \geq 2$.*

Proof. The port factor is at most one, since $x_0 x_1 \bar{x}_1 x_2 \cdots x_k \leq x_0 x_1 \cdots x_k \leq L$, so $M_k(\eta) \leq M_k(0)$ for $\eta \geq 0$ and

$$\ell_k(\eta) + (k+1)(1+\eta)\, c_{\mathrm{lcm}} \leq u(\eta) = \log M_k(0) + (1+\eta)\log(1+\eta) - \eta \log \eta + (k+1)(1+\eta)\, c_{\mathrm{lcm}}.$$

u is continuous on $[0,1]$ with $u(0) = \log M_k(0) + (k+1)c_{\mathrm{lcm}} < 0$ (37.8), so $u < 0$ on $[0, \eta_0]$ for a rational $\eta_0 > 0$. At a rational η the equation of 37.7, cleared of denominators, is an integer polynomial equation in a with the unique root in $(0, \frac{1}{2+\eta})$; the difference of its two sides is 1 at $a = 0$ and $-(1+\eta)^k (2+\eta)^{-k-2} < 0$ at $a = \frac{1}{2+\eta}$, so bisection at rational points certifies the root in rational intervals as small as asked. The two displays of 37.19 give the bound, and its last part the sign of the coefficient of $(\mathsf{T}_{k+1;(1)}[x]\, \mathbb{I}_{\mathbb{Z}})((0,\infty))$ for even k. □

50.37 Chapter 38: rays, native gauges and tiers

The proofs of this chapter rest on two readings on the sectors of the orthant: of an insertion along a ray (Lemma S19) and of the direction of a ray (Lemma S20).

Lemma S19. *Let a ray of a family on $n \geq 2$ marks be given, g an insertion as in Proposition 38.5, and π an order of $\mathcal{E}$ with the tails $U_l = \{\pi(l), \ldots, \pi(n)\}$ and the sector coordinates $q = (q_2, \ldots, q_n) \in (0,1]^{n-1}$ of Theorem 8.5(ii) on its sector H_π. On H_π*

$$g = \prod_{l=2}^{n} q_l^{\kappa_{U_l}(g)}\, g_\pi(q), \qquad f = \prod_{l=2}^{n} q_l^{\kappa_{1,U_l}}\, \varphi_\pi(q), \qquad \frac{\omega_0}{dy} = \prod_{l=2}^{n} q_l^{\kappa_{0,U_l}}\, \omega_\pi(q),$$

with $g_\pi = \prod_j k_{j,\pi}^{-a_j} \psi_{j,\pi}^{-b_j}$, $\varphi_\pi = \prod_j k_{j,\pi}^{-s_{1j}} \psi_{j,\pi}^{-t_{1j}}$ and $\omega_\pi = \prod_j k_{j,\pi}^{-s_{0j}} \psi_{j,\pi}^{-t_{0j}}$, the powers principal. These are smooth on a neighbourhood of $[0,1]^{n-1}$, and g_π, φ_π and $|\omega_\pi|$ lie between positive constants on the cube. For a function F on the orthant, homogeneous of degree 0 and integrable on the chart, $\int_{y_{e_0}=0} F\, dy = \sum_\pi \int_{(0,1]^{n-1}} F \prod_l \frac{dq_l}{q_l}$.

Proof. In the sector coordinates $\alpha_{\pi(1)} = \rho$, $\alpha_{\pi(i)} = \rho\, q_2 \cdots q_i$, one has $\alpha^u = \rho^{u\varepsilon} \prod_l q_l^{u_{U_l}}$, and by Theorem 8.5(ii) $K_j = \rho^{r_j} \prod_l q_l^{d_j(U_l)} k_{j,\pi}$ and $\Psi_j = \rho^{n-r_j} \prod_l q_l^{d_j^*(U_l)} \psi_{j,\pi}$. The three functions are homogeneous of degree 0, the data of g, of the direction and of the origin lying on the balance wall, so ρ cancels, and the exponents of the q_l are the walls at U_l of the data $(u; \mathbf{a}, \mathbf{b})$, $(\mathbf{m}_1; \mathbf{s}_1, \mathbf{t}_1)$ and $(\mathbf{m}_0; \mathbf{s}_0, \mathbf{t}_0)$. The sector letters are polynomials with nonnegative coefficients and positive constant terms, so on the cube they are at least their constant terms, and they are positive on a neighbourhood of it; their principal powers are smooth there, the modulus of a principal power

x^{-w}, $x>0$, is $x^{-\operatorname{Re} w}$, and compactness gives the bounds. The sectors cover the orthant and meet in null sets. On the chart the map $y\mapsto (y_{\pi(l-1)}-y_{\pi(l)})_{l=2}^{n}$ is linear with an integral inverse, y being recovered from the differences and from $y_{e_0}=0$, so it keeps the Lebesgue measure, and $\log q_l = y_{\pi(l)}-y_{\pi(l-1)}$ on the sector gives $dy=\prod_l dq_l/q_l$. □

Proposition 38.5 (The relations at every strength). *As stated.*

Proof. (i) Put $Y=g\,f^k\omega_0/dy$, homogeneous of degree 0. By Lemma S19, on the sector of π, $|Y|=\prod_l q_l^{c_l}\,|g_\pi\varphi_\pi^k\omega_\pi|$ with $c_l=\operatorname{Re}\kappa_{0,U_l}+\kappa_{U_l}(g)+\operatorname{Re}(k)\kappa_{1,U_l}>0$ and the last factor bounded, every nonempty proper U being a tail of some order. So Y is integrable on the chart, and it tends to 0 at infinity: a sequence leaving every compact set of the chart has, along its terms in any one sector, $\min_l q_l\to 0$, and $\prod_{l'} q_{l'}^{c_{l'}}\le q_l^{c_l}$ for every l. By 38.2(ii), $\partial_{y_e}Y=(c_e^{(0)}+k\,c_e^{(1)}+\partial_{y_e})g\cdot f^k\omega_0/dy$, and by 38.2(i) $(c_e^{(0)}+k\,c_e^{(1)}+\partial_{y_e})g$ is $(m_{0,e}+k\,m_{1,e}+u_e)\,g$ less the insertions $(s_{0j}+k\,s_{1j}+a_j)\,\theta_{j,T}\,\alpha^{\mathbf{1}_T}K_j^{-1}g$, $T\ni e$, and $(t_{0j}+k\,t_{1j}+b_j)\,\theta_{j,T}\,\alpha^{\mathbf{1}_{\mathcal{E}\setminus T}}\Psi_j^{-1}g$, $T\not\ni e$, whose walls are $\kappa_U(g)+|T\cap U|-d_j(U)\ge\kappa_U(g)$ and $\kappa_U(g)+|U\setminus T|-d_j^*(U)\ge\kappa_U(g)$ (7.13). So what precedes applies to them: $\partial_{y_e}Y$ is integrable, and its value converges absolutely. On the chart $\alpha_{e_0}=1$, for $e\ne e_0$, Fubini's theorem and $\int_{-R}^{R}\partial_{y_e}Y\,dy_e=Y|_{y_e=R}-Y|_{y_e=-R}\to 0$ give $\int\partial_{y_e}Y\,dy=0$; Y being homogeneous of degree 0, $\sum_e\partial_{y_e}Y=0$ (Euler's identity), and $\partial_{y_{e_0}}Y=-\sum_{e\ne e_0}\partial_{y_e}Y$ integrates to 0 as well. For the certificate, at such a k every value involved converges absolutely and is linear in the insertion, $\langle f^jg'\rangle_k=\langle g'\rangle_{k+j}$, and the right side has the value 0.

(ii) By Lemma S19, for $\operatorname{Re}k$ large,

$$\langle g\rangle_k=\sum_\pi\int_{[0,1]^{n-1}}\prod_l q_l^{x_l(k)-1}h_\pi(q,k)\,dq,\qquad x_l(k)=\kappa_{0,U_l}+\kappa_{U_l}(g)+k\,\kappa_{1,U_l},\quad h_\pi=g_\pi\varphi_\pi^k\omega_\pi.$$

h_π is smooth in q on a neighbourhood of the cube and entire in k, with q-derivatives continuous in (q,k) and holomorphic in k. By 8.4 each term extends meromorphically in (x,k), and its recursion, applied in every coordinate, writes it on $\{\operatorname{Re}x_l>-M\ \forall l\}$ as a finite sum of products of factors $(x_l+i)^{-1}$, at most one for each l, with functions holomorphic there. Along $x=x(k)$ each $x_l(k)+i$ is affine in k with the slope $\kappa_{1,U_l}>0$, so the composite is meromorphic on the half-plane where every $\operatorname{Re}x_l(k)>-M$, with poles only where some $x_l(k)$ is a nonpositive integer, of order at most $n-1$; M being arbitrary, this continues $\langle g\rangle_k$ to $\mathbb{C}$. On the half-plane where the integral converges absolutely it is holomorphic, and it agrees there with the continuation. An element of $\mathcal{L}$ is a finite sum $\sum_{e,i}r_{e,i}(k)(c_e^{(0)}+k\,c_e^{(1)}+\partial_{y_e})g_{e,i}$ with insertions $g_{e,i}$ of the above kind; its value is the $\mathbb{C}(k)$-linear extension of $g\mapsto\langle g\rangle_k$, which does not depend on the way the element is written, and by (i), the walls of the direction being positive, it vanishes for $\operatorname{Re}k$ large off the poles of the $r_{e,i}$, hence identically. $\langle fg\rangle_k$ and $\langle g\rangle_{k+1}$ are one integral for $\operatorname{Re}k$ large. A recurrence that follows from the relations is the value of the element $\sum_j p_j(k)f^jg$ of $\mathcal{L}$. □

Proposition 38.8 (The top and the bottom of a certificate). *As stated.*

Proof. For a polynomial $G=\sum_i k^iG^{[i]}$, with $G^{[-1]}=0$, the coefficient of k^m in $(c_e^{(0)}+k\,c_e^{(1)}+\partial_{y_e})G$ is $(c_e^{(0)}+\partial_{y_e})G^{[m]}+c_e^{(1)}G^{[m-1]}$. At $m=d$, where every $G_e^{[d]}$ vanishes, this gives the first identity, the left side having the coefficient $\sum_j c_jf^jg=\chi(f)\,g$; at $m=0$ it gives the second. At a native gauge every $c_e^{(1)}$ vanishes (Definition 38.4), so $\chi\big(f(\alpha_c)\big)g(\alpha_c)=0$. For the origin 0, $c^{(0)}=0$. □

Lemma S20. *Let a ray of a family on $n\ge 2$ marks have $\kappa_{1,S}>0$ for every nonempty proper S, with its stride f on the chart $y_{e_0}=0$.*

(i) $\mathbf{m}_1 > 0$*, the exponents of the direction are not all zero, and the tables with* $s_{1j}+t_{1j} > 0$ *form a connected family.*

(ii) The direction has a native gauge $\alpha^\star \in \mathbb{R}^{\mathcal{E}}_{>0}$*, unique up to scale; with* $\alpha^\star_{e_0} = 1$*,* $0 < f \le f(\alpha^\star)$ *on the chart with equality only at* $\log \alpha^\star$*, and* $f \le C' e^{-c'\|y\|}$ *there for some* $c', C' > 0$*.*

(iii) The Hessian of $-\log f$ *at* $\log \alpha^\star$ *on the chart is*

$$H = \Big(\sum_j \big(s_{1j}\, \kappa_{j,\alpha^\star}(X_e, X_{e'}) + t_{1j}\, \kappa_{j,(\alpha^\star)^{-1}}(X_e, X_{e'}) \big) \Big)_{e,e' \neq e_0},$$

and it is positive definite.

(iv) $\langle 1 \rangle_k = P_F(\mathbf{m}_0 + k\mathbf{m}_1; \mathbf{s}_0 + k\mathbf{s}_1, \mathbf{t}_0 + k\mathbf{t}_1)$*, and it converges absolutely exactly when* $\operatorname{Re} \kappa_{0,S} + k\kappa_{1,S} > 0$ *for every nonempty proper* S*.*

Proof. (i) Every $\{e\}$ is proper, and $\kappa_{1,\{e\}} = m_{1,e} - \sum_j \big(s_{1j} d_j(\{e\}) + t_{1j} d_j^*(\{e\}) \big)$ with $s_{1j}, t_{1j} \in \mathbb{N}$ and $d_j, d_j^* \ge 0$, so $m_{1,e} \ge \kappa_{1,\{e\}} > 0$. If every exponent of the direction were 0, the balance wall would give $m_{1,\mathcal{E}} = 0$. On the balance wall 8.16 gives $\kappa_{1,S} + \kappa_{1,\mathcal{E}\setminus S} = \sum_j (s_{1j} + t_{1j}) c_j(S)$, so every nonempty proper S has $c_j(S) > 0$ for a table with $s_{1j} + t_{1j} > 0$.

(ii) The direction is real data on its balance wall, where the target is the masses, with nonnegative exponents not all zero and positive masses. By (i) and 8.19(iii) it has a native gauge $\alpha^\star \in \mathbb{R}^{\mathcal{E}}_{>0}$, unique up to scale, the unique point up to scale at which $\alpha^{\mathbf{m}_1} \prod_j K_j^{-s_{1j}} \Psi_j^{-t_{1j}} = f$ is largest. At $y = 2z$ the stride is $e^{X_1(z)}$, X_1 the exponent of the question of the direction (17.1), and 17.4(i) and (ii) give $X_1(z) \le -2\kappa_{1,\min}(\max_e z_e - \min_e z_e) + C$; on the chart $|y_e| \le \max y - \min y$, since $y_{e_0} = 0$.

(iii) The Hessian of $\log K_j(e^y)$ in y is the covariance of the indicators of the basis under the basis law at $\alpha = e^y$ (7.16), and $\Psi_j(e^y) = e^{\langle \mathbf{1}, y \rangle} K_j(e^{-y})$, so the Hessian of $\log \Psi_j(e^y)$ is the covariance under the law at α^{-1}; at $\alpha^\star$ this gives H. For v with $v_{e_0} = 0$,

$$v^{\mathsf{T}} H v = \sum_j \Big(s_{1j} \operatorname{Var}_{\mathbb{P}_{j,\alpha^\star}} \langle \mathbf{1}_T, v \rangle + t_{1j} \operatorname{Var}_{\mathbb{P}_{j,(\alpha^\star)^{-1}}} \langle \mathbf{1}_T, v \rangle \Big) \ge 0,$$

both laws charging every basis. Let $v^{\mathsf{T}} H v = 0$ with $v \neq 0$. Then v is not constant, and $\langle \mathbf{1}_T, v \rangle$ is the same at every basis of every table with $s_{1j} + t_{1j} > 0$. Let $S = \{e : v_e = \max v\}$, nonempty and proper, and take by (i) such a table with $c_j(S) > 0$ and a basis T with $|T \cap S| < r_j(S)$. $T \cap S$ is independent in the restriction to S and not a basis of it, so some $f \in S \setminus T$ keeps it independent; the circuit of $T + f$ through f is not contained in S, and with e a mark of it outside S, $T - e + f$ is a basis with $\langle \mathbf{1}_{T-e+f}, v \rangle - \langle \mathbf{1}_T, v \rangle = v_f - v_e > 0$, a contradiction.

(iv) On the chart $\alpha_{e_0} = 1$, $\alpha^{\mathbf{m}-\mathbf{1}} \prod_{e \neq e_0} d\alpha_e = \alpha^{\mathbf{m}} dy$, so the value $\langle 1 \rangle_k = \int f^k \omega_0$ of 38.1 is the period at the point k of the ray in the form of 8.7, which converges exactly when the real parts of its proper walls $\kappa_{0,S} + k\kappa_{1,S}$ are positive; the modulus of its integrand is the integrand at the real parts of the data. □

Proposition 38.9 (The native value bounds the order). *As stated: every ray with positive direction walls, its origin complex.*

Proof. By Lemma S20(iv), $\langle 1 \rangle_k$ converges absolutely for $k \ge k_1$. The amplitude $g_0 = \omega_0 / dy = \alpha^{\mathbf{m}_0} \prod_j K_j^{-s_{0j}} \Psi_j^{-t_{0j}}$, the powers of the positive letters principal, is continuous and nowhere zero on the chart. Let $y^\star = \log \alpha^\star$ with $\alpha^\star_{e_0} = 1$. By Lemma S20(ii) and (iii), $f / f(\alpha^\star)$ is real-analytic,

has its unique maximum 1 at $y^\star$, nondegenerate with the Hessian H, and tends to 0 at infinity; so off a ball B about $y^\star$, $f \le e^{-\delta} f(\alpha^\star)$ for some $\delta > 0$, and for $k \ge k_1$

$$\Big| \int_{y_{e_0}=0,\ y\notin B} f^k g_0 \, dy \Big| \le e^{-\delta(k-k_1)} f(\alpha^\star)^{k-k_1} \int f^{k_1} |g_0| \, dy.$$

On B, Laplace's method with the continuous amplitude g_0 gives

$$\int_B f^k g_0 \, dy = f(\alpha^\star)^k \Big(\frac{2\pi}{k}\Big)^{\frac{n-1}{2}} (\det H)^{-\frac12} \big(g_0(y^\star) + o(1)\big).$$

Hence $\langle 1\rangle_k = f(\alpha^\star)^k \big(\frac{2\pi}{k}\big)^{\frac{n-1}{2}} (\det H)^{-\frac12} g_0(y^\star)(1+o(1))$ with $g_0(y^\star) \ne 0$: $\langle 1\rangle_k \ne 0$ for all large k and $\langle 1\rangle_{k+1}/\langle 1\rangle_k \to f(\alpha^\star)$. For a real origin $g_0 > 0$, and $\langle 1\rangle_k > 0$ wherever it converges.

Let $\sum_{j=0}^{h} p_j(k) \langle 1\rangle_{k+j} = 0$ for all large k, the $p_j \in \mathbb{Q}[k]$ not all zero, d their largest degree and c_j the coefficient of k^d in p_j. Dividing by $k^d \langle 1\rangle_k$ and letting $k \to \infty$ gives $\sum_j c_j f(\alpha^\star)^j = 0$, and the symbol $\sum_j c_j \lambda^j$ is a nonzero rational polynomial of degree at most h. So $f(\alpha^\star)$ is algebraic, its minimal polynomial divides the symbol, every conjugate is a root of it, and $h \ge [\mathbb{Q}(f(\alpha^\star)) : \mathbb{Q}]$. For $h = 1$ this degree is one, and a transcendental native value admits no h. □

Proposition 38.10 (The conjugates of the native value of the direction). *As stated.*

Proof. On the chart $\alpha_{e_0} = 1$ the letter complement X_F is the affine variety $\{\alpha \in (\mathbb{C}^\times)^{\mathcal{E}-e_0} : \prod_j K_j(\alpha)\Psi_j(\alpha) \ne 0\}$, and the defects $c_e^{(1)} = m_{1,e} - \sum_j \big(s_{1j} R_{j,e} + t_{1j} R^*_{j,e}\big)$ are regular functions on it with coefficients in $\Bbbk$, the direction being integral. Their sum over e is $\sum_e \partial_{y_e} \log f = 0$, f being homogeneous of degree 0, so the native gauges are the common zeros in X_F of the $c_e^{(1)}$, $e \ne e_0$: an algebraic set defined over $\Bbbk$. Its Jacobian matrix in the coordinates y_e, $e \ne e_0$, is the Hessian of $\log f$, nonsingular at $\alpha^\star$ (Lemma S20(iii)); by the holomorphic inverse function theorem $\alpha^\star$ is an isolated point of it, and an isolated point of an algebraic set defined over $\Bbbk$ has coordinates algebraic over $\Bbbk$, the irreducible components of the set being defined over the algebraic closure of $\Bbbk$. An embedding τ over $\Bbbk$ keeps every polynomial identity with coefficients in $\Bbbk$: $\tau(\alpha^\star)$ satisfies the equations of nativity, no letter vanishes at it, the Hessian determinant, a rational function over $\Bbbk$, takes there the value τ of a nonzero number, and $f\big(\tau(\alpha^\star)\big) = \tau\big(f(\alpha^\star)\big)$. Every conjugate of $f(\alpha^\star)$ over $\Bbbk$ is $\sigma\big(f(\alpha^\star)\big)$ for an embedding σ of $\Bbbk\big(f(\alpha^\star)\big)$, which extends to an embedding of the finite extension $\Bbbk(\alpha^\star)$ in the algebraically closed $\mathbb{C}$. The $[\Bbbk(\alpha^\star) : \Bbbk]$ embeddings of $\Bbbk(\alpha^\star)$ differ on a coordinate of $\alpha^\star$, so they give as many distinct nondegenerate native gauges, and Theorem 38.6(iii) bounds the dimension. Corollary 38.7 at $g = 1$ gives the last statement. □

Proposition 38.12 (The growth of the frame). *As stated.*

Proof. By 38.11, C_k is $C_{k_0}((-1)^h c)^{k-k_0}$ times $\prod_{i\le d_0} \Gamma(k-a_i) / \prod_{i\le d_h} \Gamma(k-b_i)$ times a nonzero constant. Stirling's formula, which applies to $\Gamma(k-a)$ for fixed complex a as $k \to +\infty$ along the reals, the argument staying in a sector about the positive axis, gives $\log|\Gamma(k-a)| = (k - \operatorname{Re} a - \frac12)\log k - k + O(1)$; summing, the Gammas contribute $(d_0 - d_h)(k\log k - k) + O(\log k)$. When $d_0 = d_h = d$ is the largest degree, c_0 and c_h are the leading coefficients of p_0 and p_h, both nonzero, the symbol has degree h, and the product of its roots is $(-1)^h c_0/c_h = (-1)^h c$; the term in $k\log k$ is absent and $\frac1k \log|C_k| \to \log|c|$. □

Definition 38.13 (The centre ray). As stated, for a family connected at strengths $\sigma_j \in \mathbb{N}$.

Proof. The direction $(\sigma\mathbf{1};\boldsymbol{\sigma},\boldsymbol{\sigma})$ is integral, and it is on the balance wall: $m_{1,\mathcal{E}}=n\sigma=\sum_j\sigma_j(r_j+r_j^*)$. The origin 0 is on it too. From $\Psi_j(\alpha)=\alpha^{\mathbf{1}}K_j(\alpha^{-1})$, $K_j\Psi_j=\alpha^{\mathbf{1}}K_j(\alpha)K_j(\alpha^{-1})$, and with $\sum_j\sigma_j=\sigma$ the stride is $\alpha^{\sigma\mathbf{1}}\prod_j(K_j\Psi_j)^{-\sigma_j}=\prod_j\big(K_j(e^y)K_j(e^{-y})\big)^{-\sigma_j}$ at $\alpha=e^y$. The origin form is dy, so $\langle1\rangle_k=\int_{y_{e_0}=0}f^k dy=P_F(k\sigma\mathbf{1};k\boldsymbol{\sigma},k\boldsymbol{\sigma})$ by Lemma S20(iv). The direction walls are $\sigma|S|-\sum_j\sigma_j\big(d_j(S)+d_j^*(S)\big)=\sum_j\sigma_j c_j(S)$, positive on every nonempty proper S exactly when the family is connected at the strengths (8.21(ii)). □

Theorem 38.14 (A ray is one function). *As stated, for every ray with real origin and positive direction walls.*

Proof. (i) The bounds on f are Lemma S20(ii). For $k\ge k_0$ the walls $\kappa_{0,S}+k\kappa_{1,S}\ge\kappa_{0,S}+k_0\kappa_{1,S}$ are real and positive, so $\langle1\rangle_k$ converges (Lemma S20(iv)), and its integrand $f^k\omega_0/dy$ is positive.

(ii) For $|q|<f(\alpha^\star)^{-1}$, $|qf|\le|q|f(\alpha^\star)<1$ on the chart, so $\sum_{k\ge k_0}q^{k-k_0}f^k=f^{k_0}/(1-qf)$, the partial sums dominated by $f^{k_0}/(1-|q|f(\alpha^\star))$ times the positive density ω_0/dy, which is integrable at $k=k_0$. Summing under the integral gives the first form of G, and the second is the first with numerator and denominator multiplied by $\prod_j K_j^{s_{1j}}\Psi_j^{t_{1j}}$. On smaller discs the same domination allows differentiation under the integral, $\partial_q^l(1-qf)^{-1}=l!\,f^l(1-qf)^{-l-1}$. For real $q<f(\alpha^\star)^{-1}$, $1-qf\ge\min\big(1,1-qf(\alpha^\star)\big)>0$, so the integrand is positive and at most a multiple of $f^{k_0}\omega_0/dy$.

(iii) With the positive measure $\mu=f^k\omega_0$ on the chart, $\langle1\rangle_{k+i+i'}=\int f^{i+i'}d\mu$, and the identity of Andréief gives

$$\det\Big[\int f^{i+i'}d\mu\Big]_{i,i'<h}=\frac{1}{h!}\int\det\big[f(y_a)^i\big]_{i<h,\,a\le h}^2\prod_a d\mu(y_a)=\frac{1}{h!}\int\prod_{a<b}\big(f(y_a)-f(y_b)\big)^2\prod_a d\mu(y_a),$$

positive because f is real-analytic and not constant, so that the set where two values $f(y_a)$ agree is null. If $G=N_1/N_2$ were rational, $N_2(0)\ne0$, $d=\deg N_2$, then $\sum_{i=0}^d[q^i]N_2\,\langle1\rangle_{k_0+m-i}=0$ for $m>\deg N_1$, a relation with $[q^0]N_2\ne0$ among the rows of the Hankel matrix $\big[\langle1\rangle_{k+l+i'}\big]_{l,i'\le d}$ for all large k, whose determinant would vanish, against (iii) at $h=d+1$.

On the centre ray $\kappa_{0,S}=0<\kappa_{1,S}$, so $k_0=1$, and $\alpha^\star=\mathbf{1}$ by 8.21(i). □

Theorem 38.15 (The branch at the native gauge of the direction). *As stated, for every ray with real origin and positive direction walls.*

Proof. Put $y^\star=\log\alpha^\star$, $\varphi=-\log\big(f/f(\alpha^\star)\big)\ge0$ on the chart, zero only at $y^\star$, with the Hessian H there, positive definite (Lemma S20(iii)), and $g=f^{k_0}\omega_0/dy$, positive, real-analytic and integrable. At $q=A(1-\varepsilon)$, $1-qf=1-(1-\varepsilon)e^{-\varphi}$, so for $0<\varepsilon\le1$

$$G(q)=\int\frac{g\,dy}{1-(1-\varepsilon)e^{-\varphi}}.$$

Fix a small $t_1>0$. On $\{\varphi\ge t_1\}$, $|1-(1-\varepsilon)e^{-\varphi}|\ge1-|1-\varepsilon|e^{-t_1}>0$ for $|\varepsilon|$ small, so that part of the integral is holomorphic at $\varepsilon=0$. Near $y^\star$ the real-analytic Morse lemma gives coordinates $v\in\mathbb{R}^{2a}$, $2a=n-1$, with $\varphi=\frac12|v|^2$ and $|\det\partial y/\partial v|=(\det H)^{-1/2}$ at $v=0$; for t_1 small, $\{\varphi<t_1\}$ lies in their domain. With $\tilde g=g\,|\det\partial y/\partial v|$ and

$$\beta(t)=2^{a-1}\int_{S^{2a-1}}\tilde g\big(\sqrt{2t}\,\omega\big)\,d\omega,$$

analytic near $[0,t_1]$, the spherical mean being an even analytic function of the radius, $\int_{\varphi<t} g\,dy$ has the derivative $t^{a-1}\beta(t)$. In $w=e^t-1$, $1-(1-\varepsilon)e^{-t}=e^{-t}(w+\varepsilon)$ and $e^t dt=dw$, so the part over $\{\varphi<t_1\}$ is

$$\int_0^{w_1}\frac{w^{a-1}\gamma(w)}{w+\varepsilon}\,dw,\qquad \gamma(w)=\Big(\frac{\log(1+w)}{w}\Big)^{a-1}\beta\big(\log(1+w)\big),\quad \gamma(0)=\beta(0),$$

with $\gamma=\sum_m\gamma_m w^m$ on a disc of radius $R'>w_1$, t_1 being small, so that $|\gamma_m|\le CR'^{-m}$. For $c>0$ not an integer and $|\varepsilon|<w_1$, $\varepsilon\notin(-\infty,0]$,

$$\int_0^{w_1}\frac{w^{c-1}\,dw}{w+\varepsilon}=\frac{\pi}{\sin\pi c}\,\varepsilon^{c-1}-\sum_{l\ge0}\frac{(-\varepsilon)^l w_1^{c-1-l}}{l+1-c},$$

from $\int_0^\infty w^{c-1}dw/(w+\varepsilon)=\frac{\pi}{\sin\pi c}\varepsilon^{c-1}$ at $0<\operatorname{Re}c<1$ and continuation in c; for an integer $c=N\ge1$, $w^{N-1}=\big((w+\varepsilon)-\varepsilon\big)^{N-1}$ gives the integral as $(-1)^N\varepsilon^{N-1}\log\varepsilon$ plus $(-\varepsilon)^{N-1}\log(w_1+\varepsilon)$ plus a polynomial in ε, the two last of modulus $O\big((w_1+2\rho)^{N-1}\big)$ on $|\varepsilon|\le\rho$. Summed with the weights γ_m at $c=a+m$, the singular terms give $\varepsilon^{a-1}V(\varepsilon)$ for n even and $\varepsilon^{a-1}\log\varepsilon\,V(\varepsilon)$ for n odd, with

$$V(\varepsilon)=\frac{\pi}{\sin\pi a}\,\gamma(-\varepsilon)\quad(n\text{ even}),\qquad V(\varepsilon)=(-1)^a\gamma(-\varepsilon)\quad(n\text{ odd}),$$

and the remainders converge to a function holomorphic near 0, since $|l+1-a-m|\ge\frac12$ for n even and $w_1+2\rho<R'$ for small ρ. This is the form of G, with U the sum of the remainders and the part over $\{\varphi\ge t_1\}$. Further $\beta(0)=2^{a-1}|S^{2a-1}|\,g(\alpha^\star)(\det H)^{-1/2}=(2\pi)^a g(\alpha^\star)/\big(\Gamma(a)\sqrt{\det H}\big)$, $\frac{\pi}{\sin\pi a}=\Gamma(a)\Gamma(1-a)$, and $g(\alpha^\star)=f(\alpha^\star)^{k_0}(\omega_0/dy)(\alpha^\star)=(f^{k_0-1}\omega_0/dy)(\alpha^\star)/A$, which gives $V(0)$.

$G^{(l)}(A)=l!\int f^{k_0+l}\omega_0/(1-Af)^{l+1}$ is a positive integral, and near $y^\star$, $1-Af=1-e^{-\varphi}$ is comparable with $|v|^2$, so it is finite exactly when $2(l+1)<2a$. For $l<a-1$, $G^{(l)}(q)\to G^{(l)}(A)$ as $q\uparrow A$ by monotone convergence, while the l-th derivative of $\varepsilon^{a-1}V$, resp. of $\varepsilon^{a-1}\log\varepsilon\,V$, tends to 0; so the Taylor coefficients of U of order $l<a-1$ are those of G at A, with $q-A=-A\varepsilon$, and the rest of U and $\varepsilon^{a-1}(V-V(0))$ are $O(\varepsilon^{\lceil a-1\rceil})$. On the centre ray $k_0=1$, $\alpha^\star=\mathbf{1}=(\alpha^\star)^{-1}$, $A=f(\mathbf{1})^{-1}=\prod_j K_j(\mathbf{1})^{2\sigma_j}$, $f^0\omega_0/dy=1$ and $H=2\sum_j\sigma_j\big(\kappa_{j,\mathbf{1}}(X_e,X_{e'})\big)_{e,e'\ne e_0}$. □

Proposition 38.16 (The native gauges of a centre ray). *As stated.*

Proof. The direction is $(\sigma\mathbf{1};\boldsymbol\sigma,\boldsymbol\sigma)$, so $c_e^{(1)}=\sigma-\sum_j\sigma_j\big(R_{j,e}+R^*_{j,e}\big)$ (Definition 38.1). By 7.2, $\Psi_j(\alpha)=\alpha^{\mathcal E}K_j(\alpha^{-1})$, so $R^*_{j,e}(\alpha)=\alpha_e\partial_{\alpha_e}\log\Psi_j(\alpha)=1-R_{j,e}(\alpha^{-1})$ as rational functions, the identity of 7.16 at real gauges; with $\sum_j\sigma_j=\sigma$ this gives the defects. The stride is $\prod_j\big(K_j(\alpha)K_j(\alpha^{-1})\big)^{-\sigma_j}$, a rational function homogeneous of degree 0 (Definition 38.13). □

Theorem 38.17 (Native gauges at the signs). *As stated, for the centre ray of a family.*

Proof. (i) On the chart $\alpha_{e_0}=1$, $f(\alpha)=\prod_j\big(K_j(\alpha)K_j(\alpha^{-1})\big)^{-\sigma_j}$ (38.13), so $f(\alpha^{-1})=f(\alpha)$; $\alpha\mapsto\alpha^{-1}$ keeps the letter complement, since $K_j(\alpha^{-1})\Psi_j(\alpha^{-1})=\alpha^{-2\mathbf1}\Psi_j(\alpha)K_j(\alpha)$. A point of $(\mathbb C^\times)^{\mathcal E}/\mathbb C^\times$ fixed by the inversion has α_e^2 independent of e, hence $\alpha_e=\pm1$ on the chart: the 2^{n-1} signs. By 38.2(ii) the native gauges of the ray are the critical points of $\log f$ on X_F, and the inversion, which keeps f, permutes them and keeps their native values.

(ii) At a sign η, $\Psi_j(\eta)=\eta^{\mathbf1}K_j(\eta)$, so $K_j(\eta)\ne0$ for every j puts η in X_F. In the chart $\alpha=\eta e^y$, $y_{e_0}=0$, $\alpha^{-1}=\eta e^{-y}$, so $y\mapsto\log f(\eta e^y)$ is even and its gradient vanishes at $y=0$: η is a native gauge, of native value $\prod_j\big(K_j(\eta)K_j(\eta)\big)^{-\sigma_j}$. With $K_j(\eta e^y)=\sum_T\theta_{j,T}\eta^T e^{\langle\mathbf1_T,y\rangle}=$

$K_j(\eta)\sum_T \mathbb{P}_{j,\eta}(T)e^{\langle \mathbf{1}_T,y\rangle}$, the Hessian of $\log K_j(\eta e^{y})$ at 0 is the covariance of the indicators under the signed measure $\mathbb{P}_{j,\eta}$ of total mass one, and $\log K_j(\eta e^{-y})$ has the same Hessian; so the Hessian of $-\log f$ is $2\sum_j \sigma_j\kappa_{j,\eta}$.

(iii) $W^{-1}=\prod_j (K_j\Psi_j)^{\sigma_j}$ is a polynomial, and $\partial_{y_e}\log f=\big(\sigma W^{-1}-\alpha_e\partial_e W^{-1}\big)/W^{-1}$. For a sign η, $h(y)=W^{-1}(\eta e^{y})\,e^{-\sigma\langle \mathbf{1},y\rangle}=\prod_j\big(\eta^{\mathbf{1}}K_j(\eta e^{y})K_j(\eta e^{-y})\big)^{\sigma_j}$ is even in y, so at $y=0$

$$\partial_{y_e}h=\big(\alpha_e\partial_e W^{-1}-\sigma W^{-1}\big)(\eta)=0$$

at every sign, whether or not the $K_j(\eta)$ vanish, and $W^{-1}(\eta)=\eta^{\boldsymbol{\sigma 1}}\prod_j K_j(\eta)^{2\sigma_j}$. The ring $\mathbb{Q}(\boldsymbol{\theta})[\alpha_e : e\neq e_0]/(\alpha_e^2-1)$ is the product of copies of $\mathbb{Q}(\boldsymbol{\theta})$ indexed by the signs, a class being its values at the signs, with the idempotents $2^{1-n}\prod_{e\neq e_0}(1+\eta_e\alpha_e)$, which take the value 1 at η and 0 at the other signs. So the critical polynomials vanish in it, and $W^{-1}\equiv\alpha^{\boldsymbol{\sigma 1}}\prod_j K_j^{2\sigma_j}$. Localizing at $\prod_j K_j$ keeps exactly the factors of the signs with $\prod_j K_j(\eta)\neq 0$, whose idempotents form a basis, and multiplication by $W^{-1}/\alpha^{\boldsymbol{\sigma 1}}$, $\alpha^{\boldsymbol{\sigma 1}}$ being a unit, acts on the idempotent of η by its value $\prod_j K_j(\eta)^{2\sigma_j}$. □

Theorem 38.18 (Weights that separate the signs). *As stated, for a family of N tables connected at its strengths.*

Proof. Treat the weights of all tables as variables. For a sign η, $K_j(\eta)=\sum_T \theta_{j,T}\eta^T$ is a nonzero linear form. Write $M_j=K_j(\eta)^2\big(\kappa_{j,\eta}(X_e,X_{e'})\big)_{e,e'\neq e_0}$, whose entries $K_j(\eta)\sum_{T\ni e,e'}\theta_{j,T}\eta^T-\sum_{T\ni e}\theta_{j,T}\eta^T\sum_{T\ni e'}\theta_{j,T}\eta^T$ are quadratic, and

$$D_\eta=\det\Big[\sum_j \sigma_j M_j\prod_{i\neq j}K_i(\eta)^2\Big]=\prod_i K_i(\eta)^{2(n-1)}\det\Big[\sum_j\sigma_j\kappa_{j,\eta}\Big],$$

of degree $2N(n-1)$. At $\eta=\mathbf{1}$ and unit weights $D_{\mathbf{1}}\neq 0$: the Hessian $2\sum_j\sigma_j\kappa_{j,\mathbf{1}}$ is positive definite, by the argument of Lemma S20(iii) at the strengths. The substitution $\theta_{j,T}\mapsto\theta_{j,T}\eta^T$ carries $K_j(\mathbf{1})$ to $K_j(\eta)$ and $\mathbb{P}_{j,\mathbf{1}}$ to $\mathbb{P}_{j,\eta}$, so D_η is $D_{\mathbf{1}}$ after an invertible linear substitution, and $D_\eta\neq 0$. For signs $\eta\neq\eta'$, $\prod_j K_j(\eta)^{2\sigma_j}-\prod_j K_j(\eta')^{2\sigma_j}$, of degree 2σ, is not zero: otherwise unique factorization, the linear forms $K_j(\eta)$ being irreducible and in disjoint variables for distinct j, makes $K_j(\eta)$ a multiple of $K_j(\eta')$ for every j with $\sigma_j>0$, that is $\eta^T\eta'^T$ constant on the bases of such a table; with $S=\{e:\eta_e\neq\eta'_e\}$, nonempty and proper since $\eta_{e_0}=\eta'_{e_0}$, the parity of $|T\cap S|$ is then constant, so the window $\{d_j(S),\dots,r_j(S)\}$ of 7.13 is one value and $c_j(S)=0$ for every j with $\sigma_j>0$, against connectedness. The product

$$\prod_\eta\Big(D_\eta\prod_j K_j(\eta)\Big)\prod_{\{\eta,\eta'\}}\Big(\prod_j K_j(\eta)^{2\sigma_j}-\prod_j K_j(\eta')^{2\sigma_j}\Big)$$

is a nonzero polynomial of degree $2^{n-1}\big(N+2N(n-1)\big)+2\sigma\binom{2^{n-1}}{2}=2^{n-1}\big((2n-1)N+(2^{n-1}-1)\sigma\big)$, so by the Schwartz–Zippel bound it does not vanish at some point of $\{1,\dots,D+1\}$ in every variable, D that degree. At such weights every $K_j(\eta)\neq 0$, every sign is a native gauge by 38.17(ii), nondegenerate since $D_\eta\neq 0$, and the native values are distinct. 38.6(iii) bounds the dimension below by 2^{n-1}, and 38.7 at $g=1$ the order of every recurrence that follows from the relations. □

Lemma 38.19 (Where native gauges can reach a wall). *As stated, for a family.*

Proof. (i) On the balance wall the target of the direction is $\mathbf{m}_1$, so nativity at α reads $\mathbf{m}_1 = \sum_j \big(s_{1j} R_j(\alpha) + t_{1j} R_j^*(\alpha)\big)$ (8.17). $R_{j,e} = \alpha_e \partial_e K_j / K_j = \sum_T \mathbf{1}_T(e)\, \mathbb{P}_{j,\alpha}(T)$ and $R_{j,e}^* = \sum_T \mathbf{1}_{\mathcal{E}\setminus T}(e)\, \mathbb{P}_{j,\alpha}^*(T)$, and summing over $e \in B$ gives (i).

(ii) In the coordinates (ρ, u, α_R), $\alpha^T = \rho^{|T\cap B|} u^{T\cap B} \alpha_R^{T\cap R}$, so $\sum_T |T\cap B|\, \theta_{j,T} \alpha^T = \rho\, \partial_\rho K_j$, and with $\widetilde{K}_j = \sum_l \rho^l K_j^{[l]}$, $\widetilde{\Psi}_j = \sum_l \rho^l \Psi_j^{[l]}$,

$$\kappa_{1,B} = \sum_j \Big(s_{1j}\, \frac{\rho\, \partial_\rho \widetilde{K}_j}{\widetilde{K}_j} + t_{1j}\, \frac{\rho\, \partial_\rho \widetilde{\Psi}_j}{\widetilde{\Psi}_j} \Big)$$

at every native gauge of the direction, by (i) and $\kappa_{1,B} = m_{1,B} - \sum_j \big(s_{1j} d_j(B) + t_{1j} d_j^*(B)\big)$. Along the sequence the exponents stay bounded, and $\rho_i \partial_\rho \widetilde{K}_j = O(\rho_i)$. If no bottom letter vanished at (u^*, α_R^*), every quotient would be $O(\rho_i)$ and the right side would tend to 0, while the left side tends to $\kappa_{1,B}(\mathbf{v}) > 0$. So some bottom letter vanishes there. Let it be the only one, say $K_{j_0}^{[0]}$. Then the terms of the other letters tend to 0, so $s_{1j_0}(\mathbf{v}_i)\, \rho_i \partial_\rho \widetilde{K}_{j_0} / \widetilde{K}_{j_0} \to \kappa_{1,B}(\mathbf{v})$, and since $\rho_i \partial_\rho \widetilde{K}_{j_0} \to 0$, $|s_{1j_0}(\mathbf{v}_i)/\widetilde{K}_{j_0}| \to \infty$. Nativity in a logarithmic coordinate D of u or of α_R reads

$$D \log \big(u^{\mathbf{m}_1|_B} \alpha_R^{\mathbf{m}_1|_R} \big) = \sum_j \Big(s_{1j} \frac{D\widetilde{K}_j}{\widetilde{K}_j} + t_{1j} \frac{D\widetilde{\Psi}_j}{\widetilde{\Psi}_j} \Big);$$

the left side and the terms of the other letters stay bounded, so $s_{1j_0} D\widetilde{K}_{j_0} / \widetilde{K}_{j_0}$ does, and $D\widetilde{K}_{j_0}(\rho_i, u_i, \alpha_{R,i}) \to D K_{j_0}^{[0]}(u^*, \alpha_R^*)$ must vanish. The bottom letter is homogeneous in u and in α_R, so with $K_{j_0}^{[0]}(u^*, \alpha_R^*) = 0$ Euler's identity gives the derivatives along the scalings of u and of α_R as well: the whole gradient vanishes. The same holds for a cobasis letter. If two or more bottom letters vanish, every term of the gradient of the product contains a vanishing factor; if one does, its gradient vanishes. In both cases the product vanishes at (u^*, α_R^*) with its gradient. □

Proposition 38.23 (Small lower coefficients on one parameter). *As stated, with p letters, for real C_i bounded below by a positive constant on $[0, \infty)$.*

Proof. For $\rho \geq 0$ and $\lambda > 0$, $\lambda\xi_i + \rho C_i(\rho)$ is $\lambda\xi_i$ plus a nonnegative number, so it stays in $\mathbb{C}\setminus(-\infty, 0]$, the powers are principal, and the integrand is continuous on $(0, \infty)$. Put $F_{\mathbf{a}} = G \prod_i C_i^{-w_i - a_i}$ and $c_{\mathbf{a}}(\lambda) = \prod_i \binom{-w_i}{a_i} (\lambda\xi_i)^{a_i}$, so that, wherever $|\lambda\xi_i| < |\rho C_i(\rho)|$ for every i,

$$\rho^{\kappa - 1} G \prod_i \big(\lambda\xi_i + \rho C_i\big)^{-w_i} = \rho^{\kappa^\flat - 1} F_{\mathbf{0}} \prod_i \Big(1 + \frac{\lambda\xi_i}{\rho C_i}\Big)^{-w_i} = \sum_{\mathbf{a}} c_{\mathbf{a}}(\lambda)\, \rho^{\kappa^\flat - |\mathbf{a}| - 1} F_{\mathbf{a}},$$

absolutely and uniformly where $|\lambda\xi_i| \leq \frac{1}{2} |\rho C_i(\rho)|$. Choose $b > 0$ with G and the C_i holomorphic and the C_i zero-free on a neighbourhood of $|\rho| \leq b$, and let $|C_i| \geq c > 0$ on $[0, \infty)$ and on $|\rho| \leq b$. For $|\lambda| \leq \lambda_0 = bc / (2 \max_i |\xi_i|)$ each letter $\lambda\xi_i + \rho C_i(\rho)$ has exactly one root in $|\rho| < b$ (Rouché, against $\rho C_i(\rho)$) and none on $|\rho| = b$ or on $[b, \infty)$.

The analytic part. Split the integral at b. On $[b, \infty)$ the expansion above holds uniformly and its terms are dominated by $\sum_{\mathbf{a}} \prod_i |\binom{-w_i}{a_i}| 2^{-|\mathbf{a}|}$ times $|\rho^{\kappa^\flat - 1} F_{\mathbf{0}}|$, integrable at ∞, so $\int_b^\infty = \sum_{\mathbf{a}} c_{\mathbf{a}}(\lambda) \int_b^\infty \rho^{\kappa^\flat - |\mathbf{a}| - 1} F_{\mathbf{a}}\, d\rho$, holomorphic for $|\lambda| < \lambda_0$. Let $\oint$ start at $\rho = b$ on the principal branches and run once around $|\rho| = b$; the integrand continues along it, and the expansion holds

on the circle, each $\rho^{\kappa^\flat-|\mathbf{a}|-1}$ continued along it and $F_{\mathbf{a}}$ single-valued on the disc. For $\operatorname{Re} c'>0$ and F holomorphic near the closed disc,

$$\oint_{|\rho|=b}\rho^{c'-1}F\,d\rho=\big(e^{2\pi ic'}-1\big)\int_0^b\rho^{c'-1}F\,d\rho,$$

by Cauchy's theorem on the disc cut along $[0,b]$; both sides are holomorphic in c' off $-\mathbb{N}$, the right side read with the finite part $\operatorname{Reg}\int_0^b$ (1.5, 1.7), so the identity holds at every $c'\notin\mathbb{Z}$. At $c'=\kappa^\flat-|\mathbf{a}|$, $e^{2\pi ic'}=e^{2\pi i\kappa^\flat}\neq1$. Hence

$$A_b(\lambda)=\frac{1}{e^{2\pi i\kappa^\flat}-1}\oint_{|\rho|=b}\rho^{\kappa-1}G\prod_i\big(\lambda\xi_i+\rho C_i\big)^{-w_i}d\rho=\sum_{\mathbf{a}}c_{\mathbf{a}}(\lambda)\ \operatorname{Reg}\int_0^b\rho^{\kappa^\flat-|\mathbf{a}|-1}F_{\mathbf{a}}\,d\rho$$

is holomorphic for $|\lambda|<\lambda_0$, the circle integral of an integrand holomorphic in λ along a contour that no root reaches, and the series converges there. Since $\operatorname{Reg}\int_0^\infty=\operatorname{Reg}\int_0^b+\int_b^\infty$, $A(\lambda)=A_b(\lambda)+\int_b^\infty\cdots$ is the series of the statement, holomorphic at 0.

The branch part. For $\lambda>0$ put $\rho=\lambda u$ in $\int_0^b$ and in the circle integral; $(\lambda X)^{-w}=\lambda^{-w}X^{-w}$ on the principal branches at $\lambda>0$, so both carry the factor $\lambda^{\kappa^\flat}$:

$$\int_0^b\cdots d\rho-A_b(\lambda)=\lambda^{\kappa^\flat}D_\lambda(b/\lambda),\qquad D_\lambda(R)=\int_0^R\psi_\lambda\,du-\frac{1}{e^{2\pi i\kappa^\flat}-1}\oint_{|u|=R}\psi_\lambda\,du,$$

with $\psi_\lambda(u)=u^{\kappa-1}G(\lambda u)\prod_i\big(\xi_i+uC_i(\lambda u)\big)^{-w_i}$. The roots of the letters in u are $\rho_i(\lambda)/\lambda$, where $\rho_i(\lambda)$ is the root in $|\rho|<b$; from $|\rho_iC_i(\rho_i)|=|\lambda\xi_i|$ they have modulus at most $|\xi_i|/c$. Take $R_0>2\max_i|\xi_i|/c$, so that $|uC_i(\lambda u)|>2|\xi_i|$ on $|u|=R$ for $R\geq R_0$. For $R_0\leq R\leq b/|\lambda|$, one turn around $|u|=R$ multiplies ψ_λ by $e^{2\pi i\kappa^\flat}$, the factor $u^{\kappa-1}$ giving $e^{2\pi i\kappa}$ and each letter, with one root inside, $e^{-2\pi iw_i}$; so $\frac{d}{dR}\oint_{|u|=R}\psi_\lambda\,du=\big[\psi_\lambda(Re^{i\vartheta})e^{i\vartheta}\big]_{\vartheta=0}^{2\pi}=(e^{2\pi i\kappa^\flat}-1)\psi_\lambda(R)$, and $\frac{d}{dR}D_\lambda(R)=0$. Thus $B(\lambda)=D_\lambda(R_0)$, with R_0 fixed, and $\int_0^\infty=A(\lambda)+\lambda^{\kappa^\flat}B(\lambda)$ for small $\lambda>0$. For complex λ near 0, ψ_λ is holomorphic in λ on $[0,R_0]$ and on $|u|=R_0$: there $|\lambda u|\leq|\lambda|R_0<b$, the letters do not vanish, $\xi_i+uC_i(\lambda u)$ stays off $(-\infty,0]$ on $[0,R_0]$ for λ small by compactness, and $u^{\kappa-1}$ is integrable at 0 since $\operatorname{Re}\kappa>0$. So B is holomorphic at 0, and

$$B(0)=G(0)\Big[\int_0^{R_0}u^{\kappa-1}\prod_i\big(\xi_i+uC_i(0)\big)^{-w_i}du-\frac{1}{e^{2\pi i\kappa^\flat}-1}\oint_{|u|=R_0}u^{\kappa-1}\prod_i\big(\xi_i+uC_i(0)\big)^{-w_i}du\Big],$$

independent of $R_0\geq2\max_i|\xi_i|/c$ by the same derivative. When $\operatorname{Re}\kappa^\flat<0$ the circle integral is $O(R_0^{\operatorname{Re}\kappa^\flat})$ and the bracket tends to the convergent integral $\int_0^\infty$; the bracket is holomorphic in $(\kappa,\mathbf{w})$ off $\kappa^\flat\in\mathbb{Z}$, so it is the continuation of that integral in κ and $\mathbf{w}$. Where every $\operatorname{Re}w_i>0$, $C_i(0)>0$ gives $\prod_i(\xi_i+uC_i(0))^{-w_i}=\prod_iC_i(0)^{-w_i}\prod_i(u+\xi_i/C_i(0))^{-w_i}$, and 15.1 with $J=\{1,\dots,p\}$ and the coefficients $\xi_i/C_i(0)$ gives the stacked Gamma times the Breta.

(ii) When G and the C_i are holomorphic on a neighbourhood of $[0,\infty)$, the cluster port of 38.21 with $r_i=1$ and the lower coefficients $\lambda\xi_i$, at the b chosen above, is

$$\frac{1}{2\pi i}\Big[\big(e^{2\pi i\kappa^\flat}-1\big)\int_b^\infty\cdots d\rho+\oint_{|\rho|=b}\cdots d\rho\Big]=\frac{e^{2\pi i\kappa^\flat}-1}{2\pi i}\Big(\int_b^\infty\cdots d\rho+A_b(\lambda)\Big)=\frac{e^{2\pi i\kappa^\flat}-1}{2\pi i}\,A(\lambda),$$

and it does not depend on b (38.22(i)). □

Remark. With $p=1$, $\xi_1=1$ and $C=C_1$, $\int_0^\infty u^{\kappa-1}(1+uC(0))^{-w}du = C(0)^{-\kappa}\Gamma_{\,1}^{\,2}\left[\begin{matrix}\kappa, & -\kappa^\flat\\ & w\end{matrix}\right]$, the branch part of the reference.

Definition 38.24 (Native gauges on a hypersurface; corner values). As stated.

Proof. K_X and K_Y are homogeneous, so f_X is a function on T_Z and Z_Y a hypersurface of it, and $f_X(u^{-1})=f_X(u)$ by the definition. The Cremona $u\mapsto u^{-1}$ is an automorphism of T_Z that keeps f_X and carries Z_Y onto $\{K_Y(u^{-1})=0\}$, smooth points to smooth points; so it carries the native gauges of X on Y to the critical points of the restriction of $\log f_X$ to the image, with the same values. □

Proposition 38.25 (The stride at a wall of width one). *As stated.*

Proof. By Theorem 19.4, with $K_{\mathcal{B}_R^+}(x,\alpha_R)=K_{\mathcal{B}|R}(\alpha_R)+x\,K_{\mathcal{B}/B}(\alpha_R)$ (its bases avoiding the hinge are those of $\mathcal{B}|R$ and its bases through it the $Y+g$, $Y\in\mathcal{B}/B$) and $\gamma_B^K K_{\mathcal{B}/R}=K_{\mathcal{B}|B}$,

$$K = K_{\mathcal{B}/R}(\alpha_B)\,K_{\mathcal{B}|R}(\alpha_R) + K_{\mathcal{B}|B}(\alpha_B)\,K_{\mathcal{B}/B}(\alpha_R).$$

On B the letter $K_{\mathcal{B}/R}$ is homogeneous of the degree $d=r-r(R)=d(B)$ and $K_{\mathcal{B}|B}$ of the degree $r(B)=d+1$, width one being $r(B)-d(B)=1$. So

$$K(\rho u,\alpha_R)=\rho^d\big(P+\rho Q\big),\qquad K(\rho^{-1}u^{-1},\alpha_R^{-1})=\rho^{-d}\big(\bar P+\rho^{-1}\bar Q\big),$$

and the product is $P\bar P+\rho^{-1}P\bar Q+\rho Q\bar P+Q\bar Q$, with $P\bar P=f_{\mathcal{B}/R}^{-1}(u)f_{\mathcal{B}|R}^{-1}(\alpha_R)$ and $Q\bar Q=f_{\mathcal{B}|B}^{-1}(u)f_{\mathcal{B}/B}^{-1}(\alpha_R)$. The minors inherit plain weights. For a plain table on a set Y of marks $\Psi(\alpha)=\alpha^Y K(\alpha^{-1})$, so $\Psi_{\mathcal{B}|B}(u)\Psi_{\mathcal{B}/B}(\alpha_R)=u^B\alpha_R^R\bar Q$; and by Theorem 19.4 for Ψ, $\Psi=\Psi_{\mathcal{B}/R}(\alpha_B)\Psi_{\mathcal{B}|R}(\alpha_R)+\Psi_{\mathcal{B}|B}(\alpha_B)\Psi_{\mathcal{B}/B}(\alpha_R)$, whose second term has the lower degree $|B|-r(B)$ in α_B: it is the bottom letter. The first term of K has the lower degree d: it is $\rho^d K^{[0]}$ with $K^{[0]}=P$. □

Proposition 38.26 (Corners of a wall of width one). *As stated.*

Proof. The defect is $c^{(1)}=d_y\log f$ (Lemma 38.2(ii)); in the coordinates $(\log\rho,u,\alpha_R)$, with u normalized by $u_{b_0}=1$ at a fixed $b_0\in B$ and $\alpha_{e_0}=1$, write $w_i=c^{(1)}(\alpha_i)$, with the part $w_{B,i}$ along $\log\rho$ and the part w_i' along the tori. Since Q_0,Q_1,Q_2 do not depend on ρ, $\rho\partial_\rho f^{-1}=-\rho^{-1}Q_0+\rho Q_2$, and $d\log f^{-1}=-w_i$ reads

$$-\rho^{-1}Q_0+\rho Q_2=-w_B\,f^{-1},\qquad \rho^{-1}dQ_0+dQ_1+\rho\,dQ_2=-w'\,f^{-1}$$

at α_i, with $w_B,w'\to 0$ and $f^{-1}\to\lambda^{-1}$. The point α_i is a critical point of $\log f-\langle w_i,y\rangle$, which is the logarithm of the stride of the direction with the masses moved by $-w_i$; that is the second claim before the list.

The limit. Q_2 is bounded near (u^*,α_R^*), so the first equation gives $\rho_i^{-1}Q_0\to 0$, and then $f^{-1}=\rho^{-1}Q_0+Q_1+\rho Q_2\to Q_1(u^*,\alpha_R^*)$, so $\lambda^{-1}=Q_1(u^*,\alpha_R^*)$. If no factor of $P\bar Q$ vanished at the limit, Q_0 would be bounded away from 0 and $\rho^{-1}Q_0$ unbounded.

(i) A factor of P makes $P\bar P=0$ and a factor of $\bar Q$ makes $Q\bar Q=0$; both together give $Q_1=0$, against $\lambda^{-1}\neq 0$. Let exactly one factor a vanish, with $Q_0=aG_0$, $G_0\neq 0$ near the point, and suppose its zero set smooth there, $da\neq 0$. Then $\rho^{-1}Q_0\to 0$ gives $a=o(\rho)$, and the second equation reads $\rho^{-1}G_0\,da=-dQ_1-\rho^{-1}a\,dG_0-\rho\,dQ_2-w'f^{-1}$, whose right side is bounded while the left side is not. So this case does not occur.

(ii) At the corner of K take local coordinates (a, u') on T_B and (c, α'_R) on $(\mathbb{C}^\times)^R$ with $a = K_{\mathcal{B}/R}(u)$ and $c = K_{\mathcal{B}|R}(\alpha_R)$; they exist since both zero sets are smooth, and the two functions depend on separate variables. Then $Q_0 = ac\,G$ with $G = \bar{Q}$, and $G \neq 0$ near the point, as $Q\bar{Q} = Q_1 - P\bar{P}$ is $\lambda^{-1} \neq 0$ at the point. The equations along u' and along α'_R read

$$\partial_{u'} Q_1 = -\rho^{-1} ac\, \partial_{u'} G - \rho\, \partial_{u'} Q_2 - w'_{u'} f^{-1} \to 0,$$

and likewise along α'_R, because $\rho^{-1}ac = \rho^{-1}Q_0/G \to 0$. On $\{a = c = 0\}$ the term $P\bar{P} = ac\bar{P}$ vanishes to the second order, so at the limit point the restriction of Q_1 to $\{a = c = 0\} = Z_{\mathcal{B}/R} \times Z_{\mathcal{B}|R}$ is critical, and there $Q_1 = Q\bar{Q} = f^{-1}_{\mathcal{B}|B}(u) f^{-1}_{\mathcal{B}/B}(\alpha_R)$, a product of nonvanishing functions of separate variables. Its differential along the product vanishes exactly when both factors are critical on their own zero sets, which is the claim. The corner of Ψ is the same computation with $(K_{\mathcal{B}|B}(u^{-1}), K_{\mathcal{B}/B}(\alpha_R^{-1}))$ in the place of (a, c), $G = P$, and $P\bar{P}$ the term that survives.

(iii) Let $K_{\mathcal{B}/R}$ vanish at u^* with its differential, and no other factor vanish there. Then $\rho^{-1}Q_0 \to 0$ gives $K_{\mathcal{B}/R}(u_i) = o(\rho_i)$, and $\partial_{\alpha_R} Q_0 = K_{\mathcal{B}/R}(u)\, \partial_{\alpha_R}\big(K_{\mathcal{B}|R}\bar{Q}\big)$, so $\rho^{-1}\partial_{\alpha_R} Q_0 \to 0$ and the equation along α_R gives $\partial_{\alpha_R} Q_1 \to 0$. At the limit $P\bar{P}$ vanishes with its derivatives in α_R, since it carries the factor $K_{\mathcal{B}/R}(u)$, so $f^{-1}_{\mathcal{B}|B}(u^*)\, \partial_{\alpha_R} f^{-1}_{\mathcal{B}/B}(\alpha_R^*) = 0$ with $f^{-1}_{\mathcal{B}|B}(u^*) \neq 0$: α_R^* is a critical point of $f_{\mathcal{B}/B}$ on T_R, and $\lambda^{-1} = Q\bar{Q}$ there. The other three factors are the same computation, with the equation along u when the factor lives on R, and with $P\bar{P}$ the term that survives when the factor belongs to $\bar{Q}$.

Converse. For the direction with the masses moved by $\varepsilon\mathbf{u}$ the stride is $f\,\alpha^{\varepsilon\mathbf{u}}$, and its native gauges are the solutions of $d\log f^{-1} = \varepsilon\,\mathbf{u}$ in the coordinates above, the component of $\mathbf{u}$ along $\log\rho$ being u_B. With $\rho = \varepsilon r$, $a = \rho\hat{a}$, $c = \rho\hat{c}$, so that $Q_0 = \rho^2\hat{a}\hat{c}G$ and $\rho^{-1}\partial_a Q_0 = \hat{c}G + O(\rho)$, the equations divided by ε where needed become

$$r\big(Q_2 - \hat{a}\hat{c}\,G\big) = u_B\, Q_1 + O(\varepsilon), \qquad \hat{c}\,G + \partial_a Q_1 = O(\varepsilon), \qquad \hat{a}\,G + \partial_c Q_1 = O(\varepsilon),$$
$$\partial_{u'} Q_1 = O(\varepsilon), \qquad \partial_{\alpha'_R} Q_1 = O(\varepsilon),$$

a system of $n-1$ equations in the $n-1$ unknowns $(u', \alpha'_R, \hat{a}, \hat{c}, r)$, analytic in ε. At $\varepsilon = 0$ it holds at the two constrained critical points with $\hat{a} = -\partial_c Q_1/G$, $\hat{c} = -\partial_a Q_1/G$ and $r = u_B Q_1/(Q_2 - \hat{a}\hat{c}G)$: at $a = c = 0$ the derivatives $\partial_a Q_1$ and $\partial_c Q_1$ are the multipliers, since $d(ac\bar{P}) = 0$ there, and the differential of $Q\bar{Q}$ along the zero sets vanishes, so $\hat{a}\hat{c}G = \mu_a\mu_c/G$ and r is as stated, finite by hypothesis. The Jacobian in $(u', \alpha'_R, \hat{a}, \hat{c}, r)$ is block triangular: on (u', α'_R) the Hessian of $Q\bar{Q}$ restricted to $Z_{\mathcal{B}/R} \times Z_{\mathcal{B}|R}$, which at a critical point of a product of nonvanishing functions of separate variables is the direct sum of the two constrained Hessians times nonzero constants, nonsingular by hypothesis; then G on $\hat{a}$ and on $\hat{c}$, and $Q_2 - \hat{a}\hat{c}G \neq 0$ on r. The implicit function theorem gives a solution analytic in ε; for $\varepsilon \neq 0$ it has $\rho = \varepsilon r + O(\varepsilon^2) \neq 0$ and $K = \rho^{d+1}(\rho\hat{a}\hat{c} + Q) \neq 0$, $\Psi \neq 0$ likewise, so it lies in X_F. Its native value is $e^{\varepsilon\langle\mathbf{u},y\rangle} f$, and $\varepsilon\langle\mathbf{u}, y\rangle = \varepsilon u_B \log\rho + O(\varepsilon) \to 0$, while $f \to (Q\bar{Q})^{-1}$ at the point. The corner of Ψ is the same with the pairs exchanged. □

Corollary 38.28 (The corners of a class). *As stated.*

Proof. By Proposition 21.3(i) the set C is a bunch of width one of $\mathcal{B}$ whose cell of the bunch is $\mathcal{A}$, the weights factoring, so its minors are $\mathcal{B}|C = \mathcal{A} \setminus g$, $\mathcal{B}/R = \mathcal{A}/g$, $\mathcal{B}|R = \mathcal{H} \setminus h$ and $\mathcal{B}/C = \mathcal{H}/h$ (Theorem 19.4). For a parallel class $\mathcal{A} \setminus g = \binom{C}{1}$ and $\mathcal{A}/g = \binom{C}{0}$, whose letter is the constant 1: the corner of K, which needs $K_{\mathcal{B}/R} = 0$, is empty, and $f_{\mathcal{B}/R} \equiv 1$. At the corner of Ψ the point u^* lies on the zero set of $K_{\binom{C}{1}}(u^{-1}) = \sum_{e\in C} u_e^{-1}$, which is smooth and, for $s \geq 2$, nonempty in T_C, and every point of it is a native gauge of $\mathcal{B}/R$ on $\mathcal{B}|C$ with the value 1; so $N(\mathcal{B}/R\,|\,\mathcal{B}|C) = \{1\}$ and

the corner values are $N(\mathcal{H}\setminus h\,|\,\mathcal{H}/h)$. For a series class $\mathcal{A}\setminus g=\binom{C}{C}$, whose letter is the monomial u^C, and $\mathcal{A}/g=\binom{C}{s-1}$, with the letter $u^C\sum_{e\in C}u_e^{-1}$: the corner of Ψ needs $K_{\mathcal{B}|C}(u^{-1})=0$ and is empty, $f_{\mathcal{B}|C}\equiv 1$, and at the corner of K every point of the smooth zero set of $\sum_{e\in C}u_e^{-1}$ is a native gauge of $\mathcal{B}|C$ on $\mathcal{B}/R$ with the value 1, so the corner values are $N(\mathcal{H}/h\,|\,\mathcal{H}\setminus h)$. A single mark e has $T_{\{e\}}$ a point and no hypersurface in it. □

Definition 38.29 (Asymptotic native gauges). As stated.

Proof. For the direction with the masses moved by $\mathbf{w}\in\mathbb{C}^{\mathcal{E}}$, $w_{\mathcal{E}}=0$, the stride is $f\,\alpha^{\mathbf{w}}$, whose logarithmic differential is $c^{(1)}+\mathbf{w}$; at $\mathbf{w}=-c^{(1)}(x_m)$ it vanishes at x_m, and x_m lies in the letter complement, which the masses do not change. □

Proposition 38.30 (The far points lie over the singular locus of the step letters). *As stated.*

Proof. $X_{\mathcal{E}}$ is compact and the charts of the orders cover it (Lemma 34.3(i)), so a subsequence converges to a point x^*, which lies off the torus because x_m leaves its compact subsets. Take a chart through x^*, let $I=\{i:\varepsilon_i(x^*)=0\}\neq\varnothing$ and $\mathfrak{f}=(S_i)_{i\in I}$, so that $x^*\in O_{\mathfrak{f}}$, and let $w=(\varepsilon_i)_{i\notin I}$, coordinates on $O_{\mathfrak{f}}$ near x^*. In the chart $f=\prod_{i<n}\varepsilon_i^{\kappa_{1,S_i}}\Phi^{-1}$ by Lemma 34.3(ii), the masses of the direction contributing $\prod\varepsilon_i^{m_{1,S_i}}$ and the letters their floors. The forms $d\log\varepsilon_i=dy_{e_i}-dy_{e_{i+1}}$, $i<n$, are a basis of the invariant forms on the torus, so $c^{(1)}=d_y\log f\to 0$ says

$$\varepsilon_i\partial_{\varepsilon_i}\log f=\kappa_{1,S_i}-\varepsilon_i\partial_{\varepsilon_i}\log\Phi\ \longrightarrow\ 0\qquad(i<n),$$

which is (ii). For $i\in I$: if $\Phi(x_m)$ stayed away from 0 along a subsequence, then $\varepsilon_i\partial_{\varepsilon_i}\log\Phi\to 0$, Φ being a polynomial and $\varepsilon_i\to 0$, against $\kappa_{1,S_i}>0$; so $\Phi(x^*)=0$. On $\{\varepsilon_I=0\}$, $\Phi=\prod_g\big(\prod_i g_{Z_i}\big)^{a_g}$ with the exponent $a_g\geq 1$ of the letter g in the direction (Lemma 34.3(ii), Proposition 12.20); so some factor of $\Pi_{\mathfrak{f}}$ vanishes at x^*. Suppose exactly one does, the step letter g_Z of the letter g, and that its zero set in $O_{\mathfrak{f}}$ is smooth at x^*. Near x^* every other letter has a sector letter that does not vanish, so $\Phi=G^{a_g}U$ with G the sector letter of g and U a unit, and $G|_{\varepsilon_I=0}=g_Z\,v$ with $v(x^*)\neq 0$, the product of the step letters of g at the other steps. For $i\notin I$, $\varepsilon_i(x^*)\neq 0$ and $\varepsilon_i\partial_{\varepsilon_i}\log\Phi\to\kappa_{1,S_i}$, so

$$\partial_{\varepsilon_i}\log\Phi=a_g\,\frac{\partial_{\varepsilon_i}G}{G}+\partial_{\varepsilon_i}\log U$$

stays bounded, and $\partial_{\varepsilon_i}G(x_m)\to 0$ as $G(x_m)\to 0$. At x^* this says $v\,d_w g_Z=0$, against the smoothness of the zero set of g_Z in $O_{\mathfrak{f}}$. So (i). □

Theorem 38.31 (The values along a ray). *As stated, over a subfield $\Bbbk$ of $\mathbb{C}$ containing the weights and the origin.*

Proof. (i) is the reference's (the reference, proof of thm:rayspace). The letters have their coefficients in $\Bbbk$, so X_F, the occupations and the stride are defined over $\Bbbk$, and with the origin in $\Bbbk$ and the direction integral the operators $c_e^{(0)}+k\,c_e^{(1)}+\partial_{y_e}$ map $\Bbbk[X_F]\otimes\Bbbk(k)$ to itself. Let $\mathcal{L}_{\Bbbk}$ be the $\Bbbk(k)$-span of their images and $M_{\Bbbk}=\big(\Bbbk[X_F]\otimes\Bbbk(k)\big)/\mathcal{L}_{\Bbbk}$. Since $\mathbb{C}[X_F]=\Bbbk[X_F]\otimes_{\Bbbk}\mathbb{C}$, $M_{\Bbbk}\otimes_{\Bbbk(k)}\mathbb{C}(k)$ is the quotient of 38.4, a cokernel commuting with the extension of scalars; so $\dim_{\Bbbk(k)}M_{\Bbbk}$ is the dimension d of the ray, finite by (i).

(ii) The classes of $g, fg,\dots,f^dg$ in $M_{\Bbbk}$ are $d+1$ vectors of a space of dimension d, so there are $p_0,\dots,p_d\in\Bbbk(k)$, not all zero, with $\sum_j p_j(k)\,f^jg\in\mathcal{L}_{\Bbbk}$; clearing denominators puts them in $\Bbbk[k]$. With h the largest j with $p_j\neq 0$, $h\leq d$, and 38.7 gives $\sum_{j\leq h}p_j(k)\langle g\rangle_{k+j}=0$ for all large k.

(iii) Let k_1 exceed the integer zeros of p_h and the bound of (ii). For $k \ge k_1$, $\langle g\rangle_{k+h} = -\sum_{j<h} \frac{p_j(k)}{p_h(k)} \langle g\rangle_{k+j}$ with $p_j(k)/p_h(k) \in \Bbbk$, the values of polynomials over $\Bbbk$ at integers lying in $\Bbbk$; induction on k writes every $\langle g\rangle_k$, $k \ge k_1$, as a $\Bbbk$-combination of $\langle g\rangle_{k_1}, \dots, \langle g\rangle_{k_1+h-1}$. □

Lemma 38.32 (Index by pole count). *As stated, over a subfield $\Bbbk$ of $\mathbb{C}$.*

Proof. The poles of r are rational, so its partial fractions have coefficients in $\Bbbk$: $r(k) = \sum_{h\ge1} \sum_{s=1}^{p} c_{h,s}(k+h)^{-s}$, finitely many h, $c_{h,s} \in \Bbbk$, with no polynomial part since $r \to 0$, and $\sum_h c_{h,1} = 0$ since $r(k) = O(k^{-2})$. 37.10 at $t_0 = 0$, whose identities are linear in the coefficients and hold at coefficients in any field, gives

$$\sum_{k\ge0} r(k) = \sum_{s\ge2} C_s \,(\mathsf{T}_{s;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) - \sum_{h,s} c_{h,s}\,(\mathsf{T}_{s;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,h-1]), \qquad C_s = \sum_h c_{h,s} \in \Bbbk,$$

the index-one terms regularized and their coefficient $C_1 = 0$, and every $(\mathsf{T}_{s;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,h-1])$, a finite sum of m^{-s}, rational. If $r(-M-k) = -r(k)$, uniqueness of the partial fractions gives $(-1)^s c_{M-h,s} = -c_{h,s}$, so $C_s = (-1)^{s+1}C_s$ and $C_s = 0$ for even s. For poles in one coset $-b+\mathbb{Z}$ the same computation runs in the lattice input $\mathbb{I}_{b+\mathbb{Z}}$, the sums $\sum_{k\ge0}(k+b+h)^{-s}$ being its Trailmoments at its cuts; with several cosets the index-one sums of the cosets are regularized one by one, and only their total coefficient vanishes, which leaves the differences of the index-one values of the cosets. The coefficients are in $\Bbbk$ throughout. □

50.38 Chapter 39: the two ends of a ray

The proofs of this chapter use three facts about the symmetries of Proposition 39.11: in the coordinates $y = \log\alpha$ they are linear, $y \mapsto \pm\beta^* y$; they keep the stride; and an expansion at a native gauge depends only on the Taylor series of the insertion there, which insertions realize to every finite order, $\mathbb{C}[X_F]$ containing the Laurent polynomials of degree 0.

Definition 39.1 (The module of a ray; masters; the one-step matrix). As stated.

Proof. $\mathcal{L}$ is spanned over $\mathbb{C}(k)$ by $\rho_e(g) = (c_e^{(0)} + k\,c_e^{(1)} + \partial_{y_e})g$. On $\mathbb{C}[X_F]\otimes\mathbb{C}(k)$ put $\mathrm{Sh}(g\otimes r) = fg\otimes\varsigma r$, $(\varsigma r)(k) = r(k+1)$; then $\mathrm{Sh}(r'x) = \varsigma(r')\,\mathrm{Sh}(x)$. By 38.2(ii), $\partial_{y_e}(fg) = c_e^{(1)}fg + f\,\partial_{y_e}g$, so

$$f\,\big(c_e^{(0)} + (k+1)\,c_e^{(1)} + \partial_{y_e}\big)g = \big(c_e^{(0)} + k\,c_e^{(1)} + \partial_{y_e}\big)(fg),$$

and $\mathrm{Sh}(r(k)\rho_e(g)) = r(k+1)\,\rho_e(fg) \in \mathcal{L}$. The stride is a unit of $\mathbb{C}[X_F]$, its exponents being integers and the letters units there, so Sh has the inverse $x \mapsto f^{-1}\varsigma^{-1}x$, which maps $\mathcal{L}$ into itself by the same identity read backwards: Sh descends to a bijection of $\mathfrak{M}$ with $\mathrm{Sh}(rm) = \varsigma(r)\,\mathrm{Sh}(m)$. A semilinear bijection maps bases of subspaces to bases of their images, so the classes $\mathrm{Sh}^{-1}[b_i] = [f^{-1}b_i]$ of masters of a submodule form a basis of it, and $\mathbf{B_b}$ is invertible.

Let the cyclic submodule of [1] be finite-dimensional, and let h' be the least index with $\mathrm{Sh}^{h'}[1]$ in the span W of $[1], \dots, \mathrm{Sh}^{h'-1}[1]$. Then $\mathrm{Sh}(W) \subseteq W$, and $\mathrm{Sh}(W)$ has the dimension of W, so $\mathrm{Sh}(W) = W$ and $\mathrm{Sh}^{-1}(W) = W$: W is the cyclic submodule of [1], and $h' = h$. Writing $\mathrm{Sh}^h[1]$ in the basis and clearing denominators gives a relation with $p_h \ne 0$. If $p_0 = 0$, applying Sh^{-1} to $\sum_{i=1}^{h} p_i(k)\,\mathrm{Sh}^i[1] = 0$ gives $\sum_{i=1}^{h} p_i(k-1)\,\mathrm{Sh}^{i-1}[1] = 0$, a relation among $[1], \dots, \mathrm{Sh}^{h-1}[1]$, which is impossible. Two relations of length h are proportional over $\mathbb{C}(k)$, since otherwise a combination of them eliminating $\mathrm{Sh}^h[1]$ would be a nonzero relation among the basis; with coefficients in $\mathbb{C}[k]$ without a common factor the proportionality factor is a constant. □

Definition 39.2 (Solutions). As stated.

Proof. On germs ς is bijective and $\varsigma(rx) = r(k+1)\varsigma(x)$. On $\lambda^k k^\rho\,\mathbb{C}((1/k))$, a module of rank one over $\mathbb{C}((1/k))$ with the generator $\lambda^k k^\rho$, ς is the composite of the substitution $k \mapsto k+1$, the automorphism ς_0 of the field $\mathbb{C}((1/k))$ with $\frac{1}{k} \mapsto \frac{1}{k}\big(1+\frac{1}{k}\big)^{-1}$, with the multiplication by the unit $\lambda(1+\frac{1}{k})^\rho = \lambda\sum_i \binom{\rho}{i} k^{-i}$; so it is bijective and $\varsigma(rx) = r(k+1)\varsigma(x)$ for $r \in \mathbb{C}(k) \subset \mathbb{C}((1/k))$. □

Lemma 39.3 (Solutions of distinct types). *As stated.*

Proof. With ς_0 the substitution $k \mapsto k+1$ on $\mathbb{C}((1/k))$, $\hat{A}_a(\operatorname{Sh} m) = \lambda_a(1+\frac{1}{k})^{\rho_a}\varsigma_0\big(\hat{A}_a(m)\big)$. Suppose $\sum_{a\in S} c_a\hat{A}_a = 0$ on $\mathfrak{M}$ with $c_a \in \mathbb{C}((1/k))$, every $c_a \neq 0$, and S nonempty and minimal. Applying the relation at $\operatorname{Sh} m$, and applying ς_0 to it at m, gives

$$\sum_{a\in S} c_a\lambda_a\big(1+\tfrac{1}{k}\big)^{\rho_a}\,\varsigma_0\big(\hat{A}_a(m)\big) = 0, \qquad \sum_{a\in S} \varsigma_0(c_a)\,\varsigma_0\big(\hat{A}_a(m)\big) = 0$$

for every m. The coefficient vectors of relations among the maps $\varsigma_0 \circ \hat{A}_a$, $a \in S$, form a space over $\mathbb{C}((1/k))$ of dimension one: two independent vectors in it would combine to a nonzero one with a zero coordinate, and its image under ς_0^{-1} would be a relation among fewer $\hat{A}_a$. So $c_a\lambda_a(1+\frac{1}{k})^{\rho_a} = \mu\,\varsigma_0(c_a)$ for one μ and every $a \in S$. With $c_a = c_a^0 k^{v_a}\big(1 + c_a' k^{-1} + O(k^{-2})\big)$, $c_a^0 \neq 0$, $v_a \in \mathbb{Z}$, the two sides are $c_a^0 k^{v_a}\lambda_a\big(1 + (\rho_a + c_a')k^{-1} + \cdots\big)$ and $\mu\, c_a^0 k^{v_a}\big(1 + (v_a + c_a')k^{-1} + \cdots\big)$, so $\mu = \lambda_a\big(1 + (\rho_a - v_a)k^{-1} + O(k^{-2})\big)$ for every $a \in S$: one λ, and $\rho_a - v_a$ independent of a, so all $a \in S$ have one type. Fix ρ of that type and write every A_a, $a \in S$, in $\lambda^k k^\rho\,\mathbb{C}((1/k))$, which changes the c_a by integral powers of k; then $c_a\lambda(1+\frac{1}{k})^\rho = \mu\,\varsigma_0(c_a)$ makes $c_a/\varsigma_0(c_a)$ independent of a, so every quotient c_a/c_b is fixed by ς_0. A series $r = \sum_{i\geq i_0} r_i k^{-i}$ with $\varsigma_0 r = r$ is constant: if $r_i \neq 0$ for some $i \neq 0$, the least such i gives in $\varsigma_0 r - r$ the term $-i\,r_i k^{-i-1}$ and no other of that order. So the relation is $c(k)\sum_{a\in S}\gamma_a\hat{A}_a = 0$ with constants $\gamma_a \neq 0$, and $\sum_a \gamma_a A_a = 0$ is a relation over $\mathbb{C}$ among solutions of one type: excluded. Extended $\mathbb{C}((1/k))$-linearly to $\mathfrak{N}\otimes\mathbb{C}((1/k))$, the normalizations are r independent linear forms on a space of dimension $\dim_{\mathbb{C}(k)}\mathfrak{N}$; the argument runs on $\mathfrak{N}$ in place of $\mathfrak{M}$, Sh mapping $\mathfrak{N}$ onto itself. □

Theorem 39.4 (What solutions determine). *As stated.*

Proof. (i) $V[f^{-1}b_i] = V(\operatorname{Sh}^{-1}[b_i]) = \varsigma^{-1}V[b_i]$, and $V[f^{-1}b_i] = \sum_l \mathbf{B}_{il}V[b_l]$ by $\mathbb{C}(k)$-linearity. For the values, $\langle f^{-1}b_i\rangle_k = \langle b_i\rangle_{k-1}$ (38.3).

(ii) $\operatorname{Ann}(\mathcal{S})$ is a $\mathbb{C}(k)$-subspace, and $V(\operatorname{Sh}^{\pm1} m) = \varsigma^{\pm1}V(m)$ vanishes with $V(m)$.

(iii) By (i), $\mathbf{B}'v_V - \varsigma^{-1}v_V = (\mathbf{B}'-\mathbf{B})v_V$, whose i-th entry is $V(m_i)$, $m_i = \sum_l(\mathbf{B}'-\mathbf{B})_{il}[b_l] \in \mathfrak{N}$. If a nonzero $m = \sum_l w_l[b_l]$ lies in $\operatorname{Ann}(\mathcal{S}) \cap \mathfrak{N}$, adding w to the first row of $\mathbf{B}$ gives another such matrix.

(iv) For a germ the relation of (i) holds at every integer beyond some bound, and so do the equations of a pair (cP_0, cQ_0); for a formal series they hold as identities. Conversely, let (P, Q) satisfy all the equations. By (i), $Q\,\varsigma^{-1}v_V - Pv_V = (Q\mathbf{B} - P)v_V$, so every row of $Q\mathbf{B} - P$, read in $\mathfrak{N}$, lies in $\operatorname{Ann}(\mathcal{S}) \cap \mathfrak{N} = 0$, and $P = Q\mathbf{B} = QP_0/Q_0$. If $Q = 0$ then $P = 0$. Otherwise Q_0 divides every entry of QP_0; with $d = Q_0/\gcd(Q_0, Q)$, d divides every entry of P_0 and Q_0, whose greatest common divisor is 1, Q_0 being the least common denominator, so $d = 1$, $Q = cQ_0$ and $P = cP_0$, and the degree bounds give $\deg c \leq D - D_0$. The equations are linear and homogeneous in the coefficients; for each D the solution spaces of the first N of them, in any enumeration, decrease with N in a space of finite dimension, so they are constant from some N on. □

Corollary 39.5 (One solution of an irreducible module). *As stated.*

Proof. $\mathrm{Ann}(\{V\}) \cap \mathfrak{N}$ is a submodule of $\mathfrak{N}$ (Theorem 39.4(ii)) other than $\mathfrak{N}$, hence 0. For the cyclic submodule of [1], $\sum_i p_i(k)\varsigma^i V[1] = V\big(\sum_i p_i(k)\,\mathrm{Sh}^i[1]\big) = 0$. A relation $\sum_{i<h} q_i(k)\varsigma^i V[1] = 0$ is $V(m) = 0$ with $m = \sum_{i<h} q_i(k)\,\mathrm{Sh}^i[1]$, nonzero as the $\mathrm{Sh}^i[1]$, $i < h$, are a basis; then $\mathrm{Ann}(\{V\})$ meets the cyclic submodule in a nonzero submodule, all of it, and $V[1] = 0$. □

Proposition 39.6 (The law of [1] read from a one-step matrix). *As stated.*

Proof. (i) Sh^{-1} is a bijection of $\mathfrak{M}$ with $\mathrm{Sh}^{-1}(r(k)\,m) = r(k-1)\,\mathrm{Sh}^{-1}(m)$ (Definition 39.1). For $i = 0$, $[1] = [b_1]$. If $\mathrm{Sh}^{-(i-1)}[1] = \sum_l w_{i-1,l}(k)[b_l]$, then

$$\mathrm{Sh}^{-i}[1] = \sum_l w_{i-1,l}(k-1)\,[f^{-1}b_l] = \sum_{l,l'} w_{i-1,l}(k-1)\,\mathbf{B}_{ll'}(k)\,[b_{l'}],$$

and induction gives the product form. A solution has $V \circ \mathrm{Sh}^{-i} = \varsigma^{-i} \circ V$ and is $\mathbb{C}(k)$-linear. For the values, $f^{-i} - \sum_l w_{i,l}(k)\,b_l$ lies in $\mathcal{L}$, so its value vanishes identically, and $\langle f^{-i}\rangle_k = \langle 1\rangle_{k-i}$ (Proposition 38.5(ii)).

(ii) The w_i lie in $\mathbb{C}(k)^{\mathfrak{m}}$, so $h \le \mathfrak{m}$. By (i), $\sum_i q_i(k)\,\mathrm{Sh}^{-i}[1] = 0$, and Sh^h, with $\mathrm{Sh}^h(r(k)\,m) = r(k+h)\,\mathrm{Sh}^h(m)$, turns it into $\sum_i q_i(k+h)\,\mathrm{Sh}^{h-i}[1] = 0$, which is the stated relation, $\mathrm{Sh}^j[1] = [f^j]$; the shift of the variable keeps the coefficients without a common factor. $p_0(k) = q_h(k+h) \neq 0$, since $w_0, \dots, w_{h-1}$ are independent. If $\mathbf{B}$ is invertible and $q_0 = 0$, then $\sum_{i\ge 1} q_i(k)\,w_{i-1}(k-1)\,\mathbf{B}(k) = 0$ gives $\sum_{i\ge 1} q_i(k)\,w_{i-1}(k-1) = 0$, and at $k+1$ a dependence among $w_0, \dots, w_{h-1}$ with coefficients not all zero: so $q_0 \neq 0$ and $p_h \neq 0$. Let h' be the dimension of the cyclic submodule of [1]; its basis $[1], \mathrm{Sh}[1], \dots, \mathrm{Sh}^{h'-1}[1]$ (Definition 39.1) is carried by the semilinear bijection $\mathrm{Sh}^{-(h'-1)}$ to the basis $\mathrm{Sh}^{-i}[1]$, $0 \le i < h'$. A dependence among $w_0, \dots, w_h$ gives by (i) a dependence among $[1], \dots, \mathrm{Sh}^{-h}[1]$ with the same coefficients, so $h \ge h'$. When the $[b_l]$ are a basis, a dependence among the $\mathrm{Sh}^{-i}[1]$ is one among their coordinate rows w_i, so $h = h'$, and the relation, of length h' with polynomial coefficients without a common factor, is the law of [1] up to a constant factor (Definition 39.1).

(iii) $M = [w_0; \dots; w_h]_J$ is an $(h+1) \times h$ matrix of rank h, so its left kernel is a line. It contains $(q_i)_i$, and also the vector of the signed maximal minors $\mu_i = (-1)^i \det M_{\hat{i}}$, $M_{\hat{i}}$ being M without its row i: for every column l, $\sum_i (-1)^i M_{il} \det M_{\hat{i}}$ is the expansion along its first column of the square matrix $[M_{\cdot l}\,|\,M]$, which has two equal columns; and $\mu_h = (-1)^h \det \mathbf{W}_J \neq 0$. For the divisibility, put $D_i(k) = \prod_{j=0}^{i-1} Q(k-j)$, so that $D_i w_i$ is a row of polynomials, w_i being w_0 times $\mathbf{B}(k-i+1)\cdots\mathbf{B}(k)$. The polynomial matrix $\tilde{M} = \mathrm{diag}(D_0, \dots, D_h)\,M$ has the left kernel spanned by $(q_i/D_i)_i$, and also by its signed maximal minors $\tilde{\mu}_i$, polynomials with $\tilde{\mu}_h = (-1)^h N$, $N = \det \mathbf{W}_J \prod_{i<h} D_i$. Let $\tilde{q}$ be a polynomial vector without a common factor spanning that kernel; then $\tilde{\mu} = \Lambda\tilde{q}$ with Λ a polynomial, since a denominator of Λ would divide every $\tilde{q}_i$. With $D = D_h$, the polynomial vector $(q_i D/D_i)_i$ spans the kernel, so $\tilde{q} = (q_i D/D_i)_i/g$ with g the greatest common divisor of its entries, and $\tilde{q}_h = q_h/g$ divides N. Since g divides every $q_i D$ and the q_i have no common factor, g divides D. So $q_h = g\,\tilde{q}_h$ divides $DN = \det \mathbf{W}_J \prod_{i=0}^{h} D_i = \det \mathbf{W}_J \prod_{j=0}^{h-1} Q(k-j)^{h-j}$. At k_0 with $Q(k_0 - j) \neq 0$ for $j < h$, every $D_i(k_0) \neq 0$ and the rows w_i, $i < h$, are regular, so the order of q_h at k_0 is at most that of $\det \mathbf{W}_J$, for every J with $\det \mathbf{W}_J \neq 0$: if $q_h(k_0) = 0$, every maximal minor of $\mathbf{W}(k_0)$ vanishes.

(iv) Take J all the columns. Since $w_i(k) = w_{i-1}(k-1)\mathbf{B}(k)$, $[w_1; \dots; w_h](k) = \mathbf{W}(k-1)\,\mathbf{B}(k)$, so $\mu_0 = \det \mathbf{W}(k-1) \det \mathbf{B}(k)$ and $\mu_h = (-1)^h \det \mathbf{W}(k)$, and $q_0\mu_h = q_h\mu_0$ by (iii).

(v) $\mathrm{Sh}^{-1}\big(\sum_l c_l(k)[b_l]\big) = \sum_{l,l'} c_l(k-1)\,\mathbf{B}_{ll'}(k)\,[b_{l'}]$, so the rows obey the same recursion, and the proofs of (i) to (iv) run with m in place of [1]. □

Definition 39.7 (The model of a ray). As stated.

Proof. The walls of the data of g along the ray are $\kappa_{0,S} + \kappa_S(g) + k\kappa_{1,S}$ (Proposition 38.5), and the last term grows linearly in k with $\kappa_{1,S} > 0$, so the condition holds for all large k. The form $\omega_{g,k}$ is the form of the family of the lists of F at the exponents $(a_j + s_{0j} + ks_{1j},\, b_j + t_{0j} + kt_{1j})_j$ and the masses $u + \mathbf{m}_0 + k\mathbf{m}_1$, integers on the balance wall, as $dy = \Omega_{\mathcal{E}}/\alpha^{\mathcal{E}}$ on the chart $\alpha_{e_0} = 1$ up to the sign (Definition 34.1); and $\widetilde{\sigma}_{\mathcal{E}} \subseteq V(\mathbb{R})$ with its boundary in D (Proposition 34.4(i)), so it is a class in $H_{n-1}(V, D_V)$ and the motivic period is defined. □

Proposition 39.8 (The relations of a ray are exact on its model). *As stated.*

Proof. By the proof of Definition 39.7, $\omega_{g,k}$ is the form of a family whose walls are at least 1; by Lemma 34.3(iii) it reads $\pm \prod_{i<n} \varepsilon_i^{m_i}\, h\, d\varepsilon_1 \wedge \cdots \wedge d\varepsilon_{n-1}$ in the chart of every order, with $m_i \geq 0$ the walls less one and h a product of powers of sector letters, regular off the closures of the zero sets of the letters, which V removes. So $\omega_{g,k}$ is regular on V. On the torus, for a form Φ of the top degree and a vector field ξ, $d\,\iota_\xi\Phi = L_\xi\Phi$. The field ∂_{y_e} keeps dy, so $L_{\partial_{y_e}}(u\,dy) = (\partial_{y_e}u)\,dy$, and by Lemma 38.2(ii)

$$\partial_{y_e}\big(g\, f^k\omega_0/dy\big) = \big((c_e^{(0)} + k\, c_e^{(1)} + \partial_{y_e})g\big)\, f^k\omega_0/dy.$$

In the chart of an order, $\partial_{y_e} = \sum_i (\delta_{e,e_i} - \delta_{e,e_{i+1}})\, \varepsilon_i\partial_{\varepsilon_i}$, a regular field tangent to every $D_{S_i} = \{\varepsilon_i = 0\}$. With $\Phi = \omega_{g,k}$ written as above, $\iota_{\varepsilon_i\partial_{\varepsilon_i}}\Phi$ carries the factor $\varepsilon_i^{m_i+1}$ and every $d\varepsilon_l$ with $l \neq i$, so its pullback to each D_{S_l} vanishes: at $l = i$ by the factor ε_i, at $l \neq i$ by $d\varepsilon_l$. So $\iota_{\partial_{y_e}}\omega_{g,k}$ is regular on V and vanishes on D_V, and in the relative de Rham complex of (V, D_V) the form $d\big(\iota_{\partial_{y_e}}\omega_{g,k}\big)$ is a coboundary. The second relation is the identity of forms $f\,\omega_{g,k} = \omega_{fg,k} = \omega_{g,k+1}$. □

Theorem 39.9 (A ray is one motive). *As stated.*

Proof. (i) The period of $[H, \widetilde{\sigma}_{\mathcal{E}}, \omega_{g,k}]^{\mathrm{mot}}$ is the integral of $\omega_{g,k}$ over the positive cell (Proposition 34.4(ii)), which is $\langle g\rangle_k$, the integral over the positive orthant of the chart. The motivic period is linear in the de Rham class, and by Proposition 39.8 the classes satisfy the relations. The law of [1] is an element $\sum_j p_j(k) f^j = \sum_l r_l(k)\big(c_{e_l}^{(0)} + k\, c_{e_l}^{(1)} + \partial_{y_{e_l}}\big)g_l$ of $\mathcal{L}$, a finite combination with $r_l \in \mathbb{C}(k)$ (Definition 39.1); at every integer k off the poles of the r_l and beyond the bounds of Definition 39.7 for the g_l, multiplying by $f^k\omega_0$ gives $\sum_j p_j(k)\,\omega_{1,k+j} = \sum_l r_l(k)\, d\big(\iota_{\partial_{y_{e_l}}}\omega_{g_l,k}\big)$, whose class is 0. (ii) Lemma 34.6(ii); $L(H, \widetilde{\sigma}_{\mathcal{E}})$ is the image of H_{dR}. (iii) The coaction of Definition 34.5; the left factors involve only H, $\widetilde{\sigma}_{\mathcal{E}}$ and the basis, and applying $e_i^\vee$ to the relation of (i) among the classes gives the law for the right factors. (iv) V, D_V and the forms $\omega_{g,k}$ for g with rational coefficients are defined over $\mathbb{Q}$, so their classes have rational coordinates in a rational basis; the law of [1] has coefficients in $\mathbb{Q}[k]$ up to a constant factor, the relation space being defined over $\mathbb{Q}(k)$; and $[H, \widetilde{\sigma}_{\mathcal{E}}, \omega]^{\mathrm{mot}}$ is linear in ω, so the period of $\langle 1\rangle_k^{\mathrm{mot}}$ is $\sum_i c_i(1,k)$ times the periods of the basis. □

Corollary 39.10 (The rows of the values at every order). *As stated.*

Proof. For $k \geq k_1$, $p_h(k) \neq 0$, and the relation of Theorem 39.9(i) writes $[\omega_{1,k+h}]$ as a rational combination of $[\omega_{1,k}], \ldots, [\omega_{1,k+h-1}]$; by induction W is spanned by $[\omega_{1,k_1}], \ldots, [\omega_{1,k_1+h-1}]$, so $m \leq h$. The coordinates of $[\omega_{1,k}]$ in the basis (w_l) are rational and satisfy the law because the classes do, and the period is linear, as in Theorem 39.9(iv). □

Proposition 39.11 (The symmetries of a ray). *As stated.*

Proof. $\phi_\beta \circ \phi_{\beta'} = \phi_{\beta'\circ\beta}$, the Cremona commutes with every ϕ_β and its square is the identity, so the maps ϕ_β and $\bar\phi_\beta$ form a group, and the two conditions defining a symmetry pass to composites and inverses.

(i) If β carries the tables, $K_j(\alpha\circ\beta) = \sum_{T\in\mathcal{B}_j}\theta_{j,T}\alpha^{\beta(T)} = \sum_{T'\in\mathcal{B}_{h(j)}}\theta_{h(j),T'}\alpha^{T'} = K_{h(j)}(\alpha)$, and the same with the complements gives Ψ. If β exchanges them, the sets $\beta(T)$, $T\in\mathcal{B}_j$, are the complements of the bases $\mathcal{E}\setminus\beta(T)$ of table $h(j)$, with the same weights, so $K_j(\alpha\circ\beta) = \Psi_{h(j)}(\alpha)$ and $\Psi_j(\alpha\circ\beta) = K_{h(j)}(\alpha)$. By 7.2, $K_j(\alpha^{-1}) = \alpha^{-\mathcal{E}}\Psi_j(\alpha)$ and $\Psi_j(\alpha^{-1}) = \alpha^{-\mathcal{E}}K_j(\alpha)$; with $(\alpha\circ\beta)^{\mathcal{E}} = \alpha^{\mathcal{E}}$, $K_j\big((\alpha\circ\beta)^{-1}\big) = \alpha^{-\mathcal{E}}\Psi_j(\alpha\circ\beta) = \alpha^{-\mathcal{E}}K_{h(j)}(\alpha)$, and the same for Ψ_j.

(ii) With $(\alpha\circ\beta)^u = \alpha^{u\circ\beta^{-1}}$ and $(\alpha^{-1})^u = \alpha^{-u}$, (i) gives in the four cases

$$f\circ\phi_\beta = \alpha^{\mathbf{m}_1\circ\beta^{-1}}\prod_j K_{h(j)}^{-s_{1j}}\Psi_{h(j)}^{-t_{1j}}, \qquad f\circ\phi_\beta = \alpha^{\mathbf{m}_1\circ\beta^{-1}}\prod_j \Psi_{h(j)}^{-s_{1j}}K_{h(j)}^{-t_{1j}},$$
$$f\circ\mathrm{cr} = \alpha^{-\mathbf{m}_1+2\sigma_1\mathbf{1}}\prod_j \Psi_j^{-s_{1j}}K_j^{-t_{1j}}, \qquad f\circ\bar\phi_\beta = \alpha^{-\mathbf{m}_1\circ\beta^{-1}+2\sigma_1\mathbf{1}}\prod_j K_{h(j)}^{-s_{1j}}\Psi_{h(j)}^{-t_{1j}},$$

each equal to f under the conditions with $i=1$, after reindexing the tables by h; the same computation with the data of the origin gives $(\omega_0/dy)\circ\phi = \omega_0/dy$ under the conditions with $i=0$, on X_F for an integral origin and on the positive orthant with the principal powers otherwise. In the coordinates y the maps are linear, $y\mapsto\pm\beta^*y$, and they keep the form dy on $\mathbb{C}^{\mathcal{E}}/\mathbb{C}\mathbf{1}$ up to the sign of the permutation and the factor $(-1)^{n-1}$ of the inversion; so $\phi^*\omega_0 = \pm\omega_0$ for an integral origin. The letters go to letters times monomials, so X_F is mapped onto itself, and positive gauges go to positive gauges. The value $\langle g'\circ\phi\rangle_k$ is the integral of $(g'\circ\phi)f^k(\omega_0/dy)$ against the Lebesgue measure of the quotient, which does not depend on the chart (17.1); the linear change of variables $y\mapsto\pm\beta^*y$ keeps that measure, and with $f\circ\phi = f$ and $(\omega_0/dy)\circ\phi = \omega_0/dy$ it gives $\langle g'\rangle_k$.

(iii) Substitute (i) in $\alpha^u\prod_j K_j^{-a_j}\Psi_j^{-b_j}$ and reindex the tables by h. □

Theorem 39.12 (The invariant module). *As stated.*

Proof. (i) In the coordinates y, ϕ is $y\mapsto M_\phi y$ with M_ϕ linear. For a constant vector field ξ and a function u, $(\xi u)\circ\phi = (M_\phi^{-1}\xi)(u\circ\phi)$. The relation space is spanned by $\rho_\xi(g') = \xi\big(\log(f^k\omega_0/dy)\big)g' + \xi g' = \sum_e \xi_e\big(c_e^{(0)} + k\,c_e^{(1)} + \partial_{y_e}\big)g'$, and since $\log(f^k\omega_0/dy)\circ\phi$ differs from $\log(f^k\omega_0/dy)$ by a constant (Proposition 39.11), $\rho_\xi(g')\circ\phi = \rho_{M_\phi^{-1}\xi}(g'\circ\phi)\in\mathcal{L}$. So ϕ^* is well defined on $\mathfrak{M}$, and with $(fg')\circ\phi = f\,(g'\circ\phi)$ it commutes with Sh. Then e_G is an idempotent commuting with Sh, its image and kernel are submodules with $\mathfrak{M} = e_G\mathfrak{M}\oplus(1-e_G)\mathfrak{M}$, $e_G[g'] = [e_Gg']$ with e_Gg' invariant, and the class of an invariant insertion is fixed by e_G.

(ii) $V = V\circ e_G$ vanishes on the kernel of e_G. The values are invariant by Proposition 39.11(ii). 1 is invariant, so $[1]\in\mathfrak{M}^G$, a submodule, which then contains the cyclic submodule of $[1]$.

(iii) ϕ fixes α_c and keeps f, so it maps a steepest-descent disc D_c through α_c to a disc through α_c on which $|f| < |f(\alpha_c)|$ off α_c, with $|f|\le|f(\alpha_c)|e^{-\varepsilon}$ on its boundary. In Morse coordinates v at α_c, $\log f = \log f(\alpha_c) - \frac12\sum_i v_i^2$, the homology of a small ball relative to the part where $|f|\le|f(\alpha_c)|e^{-\varepsilon}$ is $\mathbb{Z}$ in the dimension $n-1$, generated by the real ball; so $\phi(D_c)$ is $\pm D_c$ up to a boundary and pieces where $|f|\le|f(\alpha_c)|e^{-\varepsilon}$. Fix a branch of ω_0 near α_c; $(\omega_0/dy)\circ\phi$ and ω_0/dy are branches of one function there and $\phi^*dy = \pm dy$, so $\phi^*\omega_0 = c\,\omega_0$ near α_c for a constant $c\neq0$. Then $\int_{D_c}(g\circ\phi)f^k\omega_0 = c^{-1}\int_{\phi(D_c)}gf^k\omega_0$, and since $gf^k\omega_0$ is a closed form of top degree, $A_c\circ\phi^* = c'A_c$ for a constant c'. The leading coefficients of $A_c(g\circ\phi)$ and of $A_c(g)$ are $(2\pi)^{(n-1)/2}(\omega_0/dv)(\alpha_c)$ times $(g\circ\phi)(\alpha_c) = g(\alpha_c)$ (38.6(i)), and an insertion with $g(\alpha_c)\neq0$ gives $c' = 1$.

For $\phi \in G$ and $\psi \in G_c$, $A_c \circ (\phi\psi)^* = A_c \circ \psi^* \circ \phi^* = A_c \circ \phi^*$, so A_O is well defined; for $\chi \in G$, $A_O \circ \chi^* = \sum A_c \circ (\chi\phi)^*$ runs over the same cosets, so A_O is invariant, and $A_O \circ e_G = A_O$. By the argument above, $A_c \circ \phi^*$ is a constant multiple of the expansion over the disc $\phi(D_c)$, a steepest-descent disc through the native gauge $\phi(\alpha_c)$. The nondegenerate native gauges are isolated points of the critical locus, a variety, so finitely many; take an insertion g with $g(\alpha_c) = 1$ that vanishes to order N at every other one. Its expansion there vanishes to the relative order $k^{-\lceil N/2 \rceil}$, since $a_i(g)$ involves derivatives of g of order at most $2i$, so $A_O(e_G g) = A_O(g)$ has the nonzero leading coefficient of $A_c(g)$, and A_O does not vanish on $\mathfrak{M}^G$. The same insertions, applied to a relation $\sum_O \gamma_O A_O = 0$ on $\mathfrak{M}^G$ among orbits of one native value, give $\gamma_O = 0$ orbit by orbit. Lemma 39.3 gives the bound. □

Theorem 39.13 (A reversed exchange at a lean). *As stated.*

Proof. (i) $T \mapsto \mathcal{E} \setminus \beta(T)$ is a bijection of $\mathcal{B}_j$ onto $\mathcal{B}_{h(j)}$ keeping the weights, so $K_j(\mathbf{1}) = K_{h(j)}(\mathbf{1})$ and, under the weight laws, $R_{h(j),\beta(e)}(\mathbf{1}) = \mathbb{P}_{j,\mathbf{1}}\big(\beta(e) \notin \beta(T)\big) = \mathbb{P}_{j,\mathbf{1}}(e \notin T) = 1 - R_{j,e}(\mathbf{1})$. By 9.3, $\tau_e = \sum_j \big(\sigma_j + \delta_j(2R_{j,e}(\mathbf{1}) - 1)\big)$; reindexing by h, with $(\sigma_{h(j)}, \delta_{h(j)}) = (\sigma_j, \delta_j)$ (11.13), $\tau_{\beta(e)} = \sum_j \big(\sigma_j + \delta_j(1 - 2R_{j,e}(\mathbf{1}))\big) = 2\sigma - \tau_e$. The exponents (s_j, t_j) are carried by h, so Proposition 39.11(ii) applies to $\bar{\phi}_\beta$ with the masses $\boldsymbol{\tau}$, and to the ray with origin 0 and direction $(c\boldsymbol{\tau}; c\mathbf{s}, c\mathbf{t})$. For ϕ_β and cr, Proposition 39.11(i) turns the integrand into $\alpha^{\boldsymbol{\tau}\circ\beta^{-1}} \prod_j \Psi_{h(j)}^{-s_j} K_{h(j)}^{-t_j}$ and $\alpha^{-\boldsymbol{\tau}+2\sigma\mathbf{1}} \prod_j \Psi_j^{-s_j} K_j^{-t_j}$. Since $\tau_{\beta^{-1}(e)} = 2\sigma - \tau_e = \sum_j \big(\sigma_j - \delta_j(2R_{j,e}(\mathbf{1}) - 1)\big)$, the masses of $\Upsilon_{\boldsymbol{\sigma},-\boldsymbol{\delta};\mathbf{1}}$, whose exponents are (t_j, s_j), both are its integrand.

(ii) This is the exchange clause of 11.14 at the table's gauge, read on the views. In the coordinates y, Proposition 39.11(i) gives $(K_j/\Psi_j) \circ \bar{\phi}_\beta = K_{h(j)}/\Psi_{h(j)}$ and $(K_j\Psi_j) \circ \bar{\phi}_\beta = \alpha^{-2\mathcal{E}} K_{h(j)}\Psi_{h(j)}$, so, with $(\sigma_{h(j)}, \delta_{h(j)}) = (\sigma_j, \delta_j)$,

$$\Phi_{\mathbf{O}}(-\beta^* y) = \Phi_{\mathbf{O}}(y), \qquad \Phi_{\mathbf{E}}(-\beta^* y) = \Phi_{\mathbf{E}}(y) - 2\sigma\langle \mathbf{1}, y\rangle.$$

At the table's gauge $\Psi_j(e^y) = e^{\langle \mathbf{1}, y\rangle} K_j(e^{-y})$ (7.2), so $\Phi_{\mathbf{O}}(-y) = -\Phi_{\mathbf{O}}(y)$ and $\Phi_{\mathbf{E}}(-y) = \Phi_{\mathbf{E}}(y) - 2\sigma\langle \mathbf{1}, y\rangle$. For $w = v_0\mathbf{1}_e + \sum_i v_i \mathbf{1}_{g_i}$ and $w' = v_0\mathbf{1}_{\beta(e)} + \sum_i v_i \mathbf{1}_{\beta(g_i)}$, $\beta^* w' = w$ and $\langle \mathbf{1}, w'\rangle = \langle \mathbf{1}, w\rangle$, so

$$\Phi_{\mathbf{O}}(w') = \Phi_{\mathbf{O}}(-w) = -\Phi_{\mathbf{O}}(w), \qquad \Phi_{\mathbf{E}}(w') = \Phi_{\mathbf{E}}(-w) + 2\sigma\langle \mathbf{1}, w\rangle = \Phi_{\mathbf{E}}(w),$$

the identities of the views at the table's gauge. $\Phi_{\mathbf{O}}$ is linear in $\boldsymbol{\delta}$, so $-\Phi_{\mathbf{O}}^{\boldsymbol{\delta}} = \Phi_{\mathbf{O}}^{-\boldsymbol{\delta}}$, and the views, hence the readings, of $\beta(e)$ at $\boldsymbol{\delta}$ are those of e at $-\boldsymbol{\delta}$, the partners matched by β. At the centre $\Phi_{\mathbf{O}} = 0$ and e and $\beta(e)$ read alike. At a lean the partition at $-\boldsymbol{\delta}$ is that at $\boldsymbol{\delta}$ (11.2): if e and e' lie in one class at $\boldsymbol{\delta}$, they lie in one class at $-\boldsymbol{\delta}$, so $\beta(e)$ and $\beta(e')$ read alike at $\boldsymbol{\delta}$. So β maps classes into classes, and so does β^{-1}, which exchanges the family as well: β permutes the classes.

(iii) By 11.15, β maps every class of the centre onto itself. Let C split at the lean into C_K and C_Ψ, with Q the polynomial written as K from every mark of C_K and as Ψ from every mark of C_Ψ (11.17). With one table, h is the identity and Proposition 39.11(i) gives $K(\alpha \circ \beta) = \Psi(\alpha)$ and $\Psi(\alpha \circ \beta) = K(\alpha)$. For $e \in C_K$ and an order $\mathbf{g}$ of its room with $K_{e,\mathbf{g}} = Q$, put the position variables x_0 at $\beta(e)$ and x_i at $\beta(g_i)$; then $\alpha \circ \beta$ carries x_0 at e and x_i at g_i, so $\Psi_{\beta(e),\beta(\mathbf{g})} = K_{e,\mathbf{g}} = Q$ and $\beta(e) \in C_\Psi$. For $e \in C_\Psi$ with $\Psi_{e,\mathbf{g}} = Q$, $K(\alpha) = \Psi(\alpha \circ \beta)$ gives $K_{\beta(e),\beta(\mathbf{g})} = \Psi_{e,\mathbf{g}} = Q$ and $\beta(e) \in C_K$. C_K and C_Ψ have equally many marks, so $\beta(C_K) = C_\Psi$ and $\beta(C_\Psi) = C_K$. □

Definition 39.15 (Levels, wall degree, boxes). As stated.

Proof. The products of the monomials α^v, $v_{\mathcal{E}} = 0$, and of the chances $\theta_{j,T}\alpha^T/K_j$ and $\theta_{j,T}\alpha^{\mathcal{E}\setminus T}/\Psi_j$ that generate $\mathbb{C}[X_F]$ (Definition 38.1) are constant multiples of evaluations of symbols, which

therefore span it. The wall degree is the largest of finitely many numbers $-\kappa_U(g)/\kappa_{1,U}$, and $\kappa_U(g)+x\,\kappa_{1,U}\geq 0$ for every U exactly when x is at least each of them. By 38.2(i) and Definition 38.1, with $R_{j,e}=\sum_{T\ni e}\theta_{j,T}\alpha^T/K_j$ and $R^*_{j,e}=\sum_{T\not\ni e}\theta_{j,T}\alpha^{\mathcal{E}\setminus T}/\Psi_j$, the operator $c_e^{(0)}+k\,c_e^{(1)}+\partial_{y_e}$ multiplies $\alpha^u\prod_j K_j^{-a_j}\Psi_j^{-b_j}$ by

$$m_{0,e}+k\,m_{1,e}+u_e-\sum_j\big((s_{0j}+k\,s_{1j}+a_j)R_{j,e}+(t_{0j}+k\,t_{1j}+b_j)R^*_{j,e}\big),$$

and $R_{j,e}$ times the evaluation of $(u;\mathbf{a},\mathbf{b})$ is the evaluation of $\sum_{T\ni e}\theta_{j,T}(u+\mathbf{1}_T;\mathbf{a}+\mathbf{e}_j,\mathbf{b})$, and likewise for $R^*_{j,e}$; this is the evaluation of the mark relation. The letter identities evaluate to the evaluation of g times $1-K_j/K_j$, or $1-\Psi_j/\Psi_j$. The maps of the four kinds carry each letter to a letter times 1 or $\alpha^{-\mathcal{E}}$ (Proposition 39.11(i)), so do their composites, and the action of Proposition 39.11(iii) is the substitution into the evaluation. □

Proposition 39.16 (The wall degree). *As stated.*

Proof. (i) By Lemma S19, on the sector of an order π, $|g|\,f^x=\prod_l q_l^{\kappa_{U_l}(g)+x\kappa_{1,U_l}}\,|g_\pi|\varphi_\pi^x$ with the last factor between positive constants, so $|g|f^x$ is bounded on the sector exactly when every exponent is nonnegative; every nonempty proper U is a tail of some order, which gives the first statement. Likewise $|g\,f^k\omega_0/dy|$ is, on the sector of π, $\prod_l q_l^{c_l}$ times a factor between positive constants, $c_l=\operatorname{Re}\kappa_{0,U_l}+\kappa_{U_l}(g)+\operatorname{Re}(k)\kappa_{1,U_l}$, and $\int_{(0,1]^{n-1}}\prod_l q_l^{c_l-1}\,dq$ is finite exactly when every $c_l>0$; so the value converges absolutely exactly when $\operatorname{Re}\kappa_{0,U}+\kappa_U(g)+\operatorname{Re}(k)\kappa_{1,U}>0$ for every U; for the origin 0 this reads $\operatorname{Re}k>-\kappa_U(g)/\kappa_{1,U}$ for every U, and in general $\kappa_U(g)\geq-\deg_\kappa g\,\kappa_{1,U}$ gives the sufficient condition.

(ii) $\kappa_U(\alpha^u)=u_U$. For $u\neq 0$ with $u_{\mathcal{E}}=0$ some $u_e<0$, and $U=\{e\}$ is proper, $n\geq 2$, so the wall degree is positive; for $u=0$ it is 0. A monomial of $f^{-1}=\alpha^{-\mathbf{m}_1}\prod_j K_j^{s_{1j}}\Psi_j^{t_{1j}}$ is α^w with $w=-\mathbf{m}_1+\sum_j\big(\sum_{i\leq s_{1j}}\mathbf{1}_{T_{j,i}}+\sum_{i\leq t_{1j}}\mathbf{1}_{\mathcal{E}\setminus T'_{j,i}}\big)$ for bases $T_{j,i},T'_{j,i}$ of table j, and by 7.13 $w_U\geq-m_{1,U}+\sum_j\big(s_{1j}d_j(U)+t_{1j}d_j^*(U)\big)=-\kappa_{1,U}$. The walls of Laurent symbols add, so $\kappa_U(\alpha^{u+w})+(\deg_\kappa\alpha^u+1)\kappa_{1,U}\geq 0$.

(iii) The terms are g and the symbols $(u+\mathbf{1}_T;\mathbf{a}+\mathbf{e}_j,\mathbf{b})$ and $(u+\mathbf{1}_{\mathcal{E}\setminus T};\mathbf{a},\mathbf{b}+\mathbf{e}_j)$, whose walls are $\kappa_U(g)+|T\cap U|-d_j(U)$ and $\kappa_U(g)+|U\setminus T|-d_j^*(U)$, at least $\kappa_U(g)$ (7.13).

(iv) For a mark e, $\{e\}$ is proper, and $\kappa_{\{e\}}(g)\geq-x\,\kappa_{1,\{e\}}$ bounds u_e from below at a fixed level; with $u_{\mathcal{E}}$ fixed by the level, u is bounded from above as well.

(v) A symmetry maps the positive orthant onto itself and keeps f (Proposition 39.11(ii)), and the evaluation of ϕ^*g is that of g composed with ϕ, so $|\phi^*g|f^x$ and $|g|f^x$ have the same bound, and (i) gives the same wall degree. The action of Proposition 39.11(iii) maps the level $(\mathbf{0},\mathbf{0})$ to itself. □

Lemma 39.17 (The Laurent part). *As stated.*

Proof. $\mathfrak{M}$ is finite-dimensional (Theorem 38.31(i)). The direction has $s_{1j},t_{1j}\in\mathbb{N}$, so f^{-1} is a Laurent polynomial and $\operatorname{Sh}^{-1}[\alpha^v]=[f^{-1}\alpha^v]$ lies in $\mathfrak{M}_{\mathrm{L}}$: Sh^{-1} maps $\mathfrak{M}_{\mathrm{L}}$ into itself, injectively and semilinearly, hence onto itself, and $\mathfrak{M}_{\mathrm{L}}$ is a submodule. It contains [1], and $[g]=\operatorname{Sh}^l[f^{-l}g]$. When $s_{1j},t_{1j}\geq 1$ for every j, $f^{-l}\alpha^u\prod_j K_j^{-a_j}\Psi_j^{-b_j}$ is a Laurent polynomial as soon as l is at least every a_j and every b_j. The symmetries map Laurent insertions to Laurent insertions (Proposition 39.16(v)), so $e_G\mathfrak{M}_{\mathrm{L}}\subseteq\mathfrak{M}_{\mathrm{L}}\cap\mathfrak{M}^G$, and an element x of the intersection is e_Gx; the intersection of two submodules is one (Theorem 39.12(i)), and e_G of a Laurent insertion is invariant. □

Proposition 39.18 (The relations of a box). *As stated.*

Proof. (i) The terms of a letter identity of a symbol $(u;\mathbf{a},\mathbf{b})$ of the box for K_j, $a_j < \bar a_j$, are at levels at most the bounds and of wall degree at most that of the symbol (Proposition 39.16(iii)); likewise for Ψ_j. A term of the mark relation of a stem at the level $(\bar{\mathbf{a}}^- + \mathbf{e}_j, \bar{\mathbf{b}}^-)$ has the coefficient $s_{0j} + k\, s_{1j} + \bar a_j^-$; if $\bar a_j \geq 1$ its level is at most $(\bar{\mathbf{a}}, \bar{\mathbf{b}})$, and if $\bar a_j = 0$ then K_j is not active and $\bar a_j^- = 0$, so the coefficient vanishes identically and the term is omitted; likewise for Ψ_j, and the wall degrees do not grow. The evaluations are those of Definition 39.15(iii), and Proposition 38.5(ii) gives the identity in k.

(ii) A letter identity of a symbol $x = (u;\mathbf{a},\mathbf{b})$ of the box for K_j, $a_j < \bar a_j$, makes x congruent to a combination of symbols of the box at the level $(\mathbf{a}+\mathbf{e}_j, \mathbf{b})$, by (i). Repeating, every formal combination y is congruent modulo the letter identities to a combination $y' = \sum_u c_u(u;\bar{\mathbf{a}},\bar{\mathbf{b}})$ of symbols at the top level, with distinct u. The letter identities evaluate to 0, so if y evaluates to 0, so does y', and $\prod_j K_j^{\bar a_j} \Psi_j^{\bar b_j}$ times its evaluation is the Laurent polynomial $\sum_u c_u \alpha^u$, which is 0 only when every c_u is: $y' = 0$, and y is a combination of letter identities.

(iii) Let $x = (u;\mathbf{a},\mathbf{b})$ be such a symbol and $\prod_j K_j^{\bar a_j^- - a_j} \Psi_j^{\bar b_j^- - b_j} = \sum_v \lambda_v \alpha^v$, $\lambda_v \in \Bbbk$. Then x and $\sum_v \lambda_v\, s_v$, $s_v = (u+v;\bar{\mathbf{a}}^-, \bar{\mathbf{b}}^-)$, have one evaluation. Each v is a sum of $\bar a_j^- - a_j$ indicators of bases and $\bar b_j^- - b_j$ of complements of bases of every table j, so $\kappa_U(s_v) \geq \kappa_U(x)$ (7.13) and the s_v are stems. The formal combination $\mathrm{MR}_e(x) - \sum_v \lambda_v \mathrm{MR}_e(s_v)$ evaluates to $(c_e^{(0)} + k\, c_e^{(1)} + \partial_{y_e})$ of 0, and its terms lie in the box: those of $\mathrm{MR}_e(s_v)$ by (i), and those of $\mathrm{MR}_e(x)$ because their wall degree is at most $\deg_\kappa x \leq \mathfrak{t}$ and a term at the level $(\mathbf{a}+\mathbf{e}_j, \mathbf{b})$, with $a_j \leq \bar a_j^-$, either has a level within the bounds, when $\bar a_j \geq 1$, or the coefficient $s_{0j} + k\, s_{1j}$, identically 0, when $\bar a_j = 0$; likewise for Ψ_j. By (ii) it is a combination of letter identities, and $\mathrm{MR}_e(x) \in \mathcal{R}_{\mathfrak{B}}$.

(iv) ϕ permutes the letters keeping the bounds, so it maps the levels within the bounds onto themselves and the level of the stems onto itself, and it keeps the wall degree (Proposition 39.16(v)); so it permutes the symbols of the box and the stems. The image of a letter identity of the box evaluates to 0 and has its terms in the box, so it lies in the span of the letter identities by (ii). The image of the mark relation of a stem s at e evaluates to $\big((c_e^{(0)} + k\, c_e^{(1)} + \partial_{y_e})s\big) \circ \phi$, which is $\sum_{e'} \mu_{e'}(c_{e'}^{(0)} + k\, c_{e'}^{(1)} + \partial_{y_{e'}})(s \circ \phi)$ for constants $\mu_{e'}$, ϕ being linear in the coordinates y and keeping $\log(f^k \omega_0/dy)$ up to a constant (proof of Theorem 39.12(i)); so the image less $\sum_{e'} \mu_{e'} \mathrm{MR}_{e'}(\phi^* s)$, with $\phi^* s$ a stem, evaluates to 0 and lies in the span of the letter identities by (ii). So ϕ maps $\mathcal{R}_{\mathfrak{B}}$ into itself, and onto itself, G being finite. Then $e_G \mathcal{R}_{\mathfrak{B}} \subseteq \mathcal{R}_{\mathfrak{B}} \cap \mathcal{F}_{\mathfrak{B}}^G$, and an element x of the intersection is $e_G x$. □

Proposition 39.19 (The closing relations have more solutions than the ray). *As stated.*

Proof. With $\mathbf{s}_0 = \mathbf{t}_0 = \mathbf{0}$, $\omega_0/dy = \alpha^{\mathbf{m}_0}$ and $c_e^{(0)} = m_{0,e}$, and $c_e^{(1)} = \partial_{y_e} \log f = -\partial_{y_e} f^{-1}/f^{-1}$ (38.2(ii)), so

$$\big(c_e^{(0)} + k\, c_e^{(1)} + \partial_{y_e}\big)\big(\alpha^w f^{-1}\big) = \alpha^w \big((m_{0,e} + w_e)\, f^{-1} + (1-k)\, \partial_{y_e} f^{-1}\big),$$

which is the stated Laurent polynomial, $\partial_{y_e} \alpha^v = v_e \alpha^v$; it lies in $\mathcal{L}$, $\alpha^w f^{-1}$ being an insertion. (i) The evaluation at z is multiplicative on Laurent polynomials and gives $z^w\big((m_{0,e}+w_e) f^{-1}(z) + (1-k)\,(\partial_{y_e} f^{-1})(z)\big) = 0$. (ii) It gives $q_0 + \sum_{i\geq 1} q_i\, f^{-1}(z)^i = q_0$. Applying Sh^{-h}, with $\mathrm{Sh}^{-h}(r(k)\, m) = r(k-h)\, \mathrm{Sh}^{-h}(m)$, to the law of [1] gives $\sum_j p_j(k-h)[f^{j-h}] = 0$, the element of the statement, whose coefficient at f^0 is $p_h(k-h) \neq 0$. A linear form that vanishes on $\mathcal{L}$ and agrees with the evaluation at z on the Laurent insertions would vanish on that element and take there the value $p_h(k-h)$. □

Definition 39.20 (The reduction of a box). As stated.

Proof. By Proposition 39.18(iv) each $\phi \in G$ permutes the symbols of the box, so $e_G g$ is the mean of the symbols of the orbit of g; orbit averages of distinct orbits have disjoint supports, and they span $\mathcal{F}_{\mathfrak{B}}^G$. The wall degree is constant on an orbit and ϕ^* keeps the Laurent symbols, as do the inverses (Proposition 39.16(v)). Gaussian elimination in the order of the ranking gives a basis (r_p) of $\mathcal{R}_{\mathfrak{B}}^G$, indexed by the pivots, in which r_p is led by p with the coefficient 1 and involves no other pivot. For $x \in \mathcal{F}_{\mathfrak{B}}^G$, $x - \sum_p x_p\, r_p$, x_p the coefficient of the average of p in x, involves no pivot and is congruent to x; two such combinations differ by an element of $\mathcal{R}_{\mathfrak{B}}^G$ that involves no pivot, which is 0, since a nonzero element is led by a pivot. Every r_p involves only orbits ranked at most p, which gives the last statement of (ii). No orbit ranks below that of 1: the other Laurent orbits have positive wall degree (Proposition 39.16(ii)). If it were a pivot, $r_1 = 1$ would lie in $\mathcal{R}_{\mathfrak{B}}^G \subseteq \mathcal{R}_{\mathfrak{B}}$ (Proposition 39.18(iv)), and 1 would evaluate into $\mathcal{L}$ (Proposition 39.18(i)), $[1] = 0$; but the values vanish on $\mathcal{L}$ (Proposition 38.5(ii)), and $\langle 1\rangle_k \neq 0$ for all large k (Proposition 38.9). The monomials of $f^{-1}b_i$ have wall degree at most $\mathfrak{s}+1 \leq \mathfrak{t}$ (Proposition 39.16(ii)), and f^{-1} has its coefficients in $\Bbbk$, so $f^{-1}b_i \in \mathcal{F}_{\mathfrak{B}}$; on Laurent combinations the formal and the evaluated products agree, distinct Laurent monomials being independent functions, and $f \circ \phi = f$, so $f^{-1}b_i$ is invariant. □

Theorem 39.21 (The box gives a spanning set, the one-step matrix and a certificate). *As stated.*

Proof. (i) $f^{-1}b_i - \sum_l \mathbf{B}_{il} b_l$ lies in $\mathcal{R}_{\mathfrak{B}}^G \subseteq \mathcal{R}_{\mathfrak{B}}$, so its evaluation lies in $\mathcal{L}$ (Proposition 39.18(i), (iv)), and $[f^{-1}b_i] = \sum_l \mathbf{B}_{il}[b_l]$. With $\mathfrak{N}$ the span of the $[b_l]$, $\mathrm{Sh}^{-1}\mathfrak{N} \subseteq \mathfrak{N}$; Sh^{-1} is injective and semilinear, so it keeps dimensions, $\mathrm{Sh}^{-1}\mathfrak{N} = \mathfrak{N}$, and $\mathfrak{N}$ is a submodule; it contains $[b_1] = [1]$. The b_l are invariant insertions, so $\mathfrak{N} \subseteq \mathfrak{M}^G$ (Theorem 39.12(i)). An invariant combination of Laurent symbols of wall degree at most $\mathfrak{s}$ is a combination of averages of Laurent orbits of wall degree at most $\mathfrak{s}$, and by the ranking every orbit ranked at most the highest of these is a Laurent orbit of wall degree at most $\mathfrak{s}$; so its reduction is a combination of the b_l (Definition 39.20(ii)), congruent to it modulo $\mathcal{R}_{\mathfrak{B}}^G$, and it has a class in $\mathfrak{N}$. When the $[b_l]$ are independent they are a basis of $\mathfrak{N}$, and the matrix of Sh^{-1} on a basis is unique.

(ii) As an element of $\mathcal{R}_{\mathfrak{B}}$, $f^{-1}b_i - \sum_l \mathbf{B}_{il} b_l$ is a combination of letter identities and of mark relations $\mathrm{MR}_e(s)$ of stems s, with coefficients $\nu_{i,e,s} \in \Bbbk(k)$. Evaluated, the letter identities give 0 and $\mathrm{MR}_e(s)$ gives $(c_e^{(0)} + k\, c_e^{(1)} + \partial_{y_e})s$; put $G_{i,e} = \sum_s \nu_{i,e,s}\, s$.

(iii) $V[f^{-1}b_i] = V(\mathrm{Sh}^{-1}[b_i]) = \varsigma^{-1}V[b_i]$, and by (i) and the $\mathbb{C}(k)$-linearity of V it is $\sum_l \mathbf{B}_{il} V[b_l]$. The certificate is an element of $\mathcal{L}$, so its value vanishes identically, and $\langle f^{-1}b_i\rangle_k = \langle b_i\rangle_{k-1}$ (Proposition 38.5(ii)). At a real k as stated, the stems, the b_l and the monomials of $f^{-1}b_i$ have wall degree at most $\mathfrak{t}$, so their values converge absolutely (Proposition 39.16(i)), and Proposition 38.5(i) gives the value 0 for every term $(c_e^{(0)} + k\, c_e^{(1)} + \partial_{y_e})s$.

(iv) Write $\rho_e^{(k)} = c_e^{(0)} + k\, c_e^{(1)} + \partial_{y_e}$; by the identity in the proof of Definition 39.1, $f^{-1}\rho_e^{(k-1)}(x) = \rho_e^{(k)}(f^{-1}x)$ and $f^h \rho_e^{(k)}(x) = \rho_e^{(k-h)}(f^h x)$. With the $G_{l,e}$ of (ii), put $G_e^{(0)} = 0$ and $G_e^{(i)}(k) = \sum_l w_{i-1,l}(k-1)\, G_{l,e}(k) + f^{-1}G_e^{(i-1)}(k-1)$ for $i \geq 1$, and $R_i(k) = \sum_e \rho_e^{(k)}\big(G_e^{(i)}(k)\big) \in \mathcal{L}$. Then $f^{-i} = \sum_l w_{i,l}(k)\, b_l + R_i(k)$: for $i = 0$ this is $1 = b_1$, and multiplying the identity for $i-1$ at the strength $k-1$ by f^{-1} and inserting $f^{-1}b_l = \sum_{l'} \mathbf{B}_{ll'}(k) b_{l'} + \sum_e \rho_e^{(k)}(G_{l,e}(k))$ gives it for i. So $\sum_i q_i(k) f^{-i} = \sum_i q_i(k) R_i(k)$, and multiplying by f^h and replacing k by $k+h$ gives

$$\sum_{j=0}^{h} p_j(k)\, f^j = \sum_e \rho_e^{(k)}\Big(\sum_{i=0}^{h} q_i(k+h)\, f^h G_e^{(i)}(k+h)\Big),$$

a certificate. Proposition 39.6(ii) gives the rest. □

Theorem 39.22 (The search stops). *As stated.*

Proof. Let $\mathcal{L}_\Bbbk$ be the $\Bbbk(k)$-span of the elements $(c_e^{(0)} + k\,c_e^{(1)} + \partial_{y_e})x$, $x \in \Bbbk[X_F]$, and $M_\Bbbk = (\Bbbk[X_F] \otimes \Bbbk(k))/\mathcal{L}_\Bbbk$. As in the proof of Theorem 38.31, $M_\Bbbk \otimes_{\Bbbk(k)} \mathbb{C}(k) = \mathfrak{M}$, so $M_\Bbbk$ has the finite dimension of the ray and embeds in $\mathfrak{M}$, and a $\Bbbk(k)$-subspace S of $M_\Bbbk$ has $(S \otimes \mathbb{C}(k)) \cap M_\Bbbk = S$, a basis of S extending to one of $M_\Bbbk$. The symmetries act on $M_\Bbbk$ as on $\mathfrak{M}$, the weights being in $\Bbbk$. Let $\mathfrak{N}_\mathfrak{s} \subseteq M_\Bbbk$ be the span of the classes of the averages of the Laurent orbits of wall degree at most $\mathfrak{s}$. The $\mathfrak{N}_\mathfrak{s}$ increase with $\mathfrak{s}$ in a space of finite dimension, so they are constant from some $\mathfrak{s}_0$ on, and their union is the span of the classes of the invariant Laurent insertions, whose $\mathbb{C}(k)$-span in $\mathfrak{M}$ is $e_G\mathfrak{M}_\mathrm{L}$ (Lemma 39.17).

The averages $\bar g$ of the Laurent orbits of wall degree at most $\mathfrak{s}_0 + 1$ are finitely many (Proposition 39.16(iv)), and each has its class in $\mathfrak{N}_{\mathfrak{s}_0}$:

$$\bar g - \sum_{\bar h} \lambda_{\bar g,\bar h}\,\bar h = \sum_{e,i} \nu_{\bar g,e,i}\,(c_e^{(0)} + k\,c_e^{(1)} + \partial_{y_e})G_{\bar g,i},$$

with $\bar h$ running over the averages of the Laurent orbits of wall degree at most $\mathfrak{s}_0$, $\lambda, \nu \in \Bbbk(k)$, and finitely many symbols $G_{\bar g,i}$, the evaluations of the symbols spanning $\Bbbk[X_F]$ over $\Bbbk$. Take an integer $\mathfrak{t} \geq \mathfrak{s}_0 + 1$ at least the wall degree of every $G_{\bar g,i}$, and the level bounds $\bar\ell(L) = 1 + \max \ell(L)$ for every letter L, the maximum over the levels ℓ of the symbols $\phi^* G_{\bar g,i}$, $\phi \in G$, at L. These bounds are at least 1, and kept by G, the set of the $\phi^* G_{\bar g,i}$ being kept by G; every $G_{\bar g,i}$ is at a level at most $(\bar{\mathbf{a}}^-, \bar{\mathbf{b}}^-)$, here $\bar a_j^- = \bar a_j - 1$ and $\bar b_j^- = \bar b_j - 1$. By Proposition 39.18(iii) every $\mathrm{MR}_e(G_{\bar g,i})$ lies in $\mathcal{R}_\mathfrak{B}$, and the formal combination $\bar g - \sum \lambda_{\bar g,\bar h}\bar h - \sum \nu_{\bar g,e,i}\mathrm{MR}_e(G_{\bar g,i})$ has its terms in the box (Proposition 39.16(iii)) and evaluates to 0, so it lies in $\mathcal{R}_\mathfrak{B}$ (Proposition 39.18(ii)). Hence $\bar g - \sum \lambda_{\bar g,\bar h}\bar h$, which is invariant, lies in $\mathcal{R}_\mathfrak{B} \cap \mathcal{F}_\mathfrak{B}^G = \mathcal{R}_\mathfrak{B}^G$ (Proposition 39.18(iv)).

Take $\mathfrak{s} = \mathfrak{s}_0 < \mathfrak{t}$. A target $f^{-1}b_i$ is an invariant combination of Laurent symbols of wall degree at most $\mathfrak{s}_0 + 1$ (Proposition 39.16(ii)), so a combination of the $\bar g$, and it is congruent modulo $\mathcal{R}_\mathfrak{B}^G$ to a combination of averages of Laurent orbits of wall degree at most $\mathfrak{s}_0$. The reduction of that combination, which is the reduction of the target, involves only free Laurent orbits of wall degree at most $\mathfrak{s}_0$ (Definition 39.20(ii)): the spanning set. So the box is accepted at $\mathfrak{s}_0$, and its spanning set spans $\mathfrak{N}_{\mathfrak{s}_0} \otimes \mathbb{C}(k) = e_G\mathfrak{M}_\mathrm{L}$, by Theorem 39.21(i); this is $\mathfrak{M}^G$ when every letter exponent of the direction is positive (Lemma 39.17). A search through all the quadruples reaches this one, and acceptance is decided by finitely many operations in $\Bbbk(k)$. □

Definition 39.23 (Sources; regular points; the normal density). As stated.

Proof. Z is irreducible, so its smooth locus is connected; there $d\log f$ vanishes along Z, so f is constant on it, and on Z by continuity. Differentiating $d\log f = 0$ along Z shows that the tangent space of Z at a smooth point lies in the kernel of the Hessian, whose rank is then at most $n - 1 - d$; the conditions defining a regular point are open, so the regular points form an open set, dense when it is nonempty, Z being irreducible. For another choice of coordinates (u', w') with $Z = \{w' = 0\}$, at $w = 0$ one has $u' = U(u)$ and $w' = J(u)w + O(|w|^2)$, the Jacobian of $(u, w) \mapsto (u', w')$ being block triangular there, so $du' \wedge dw' = \det(\partial U/\partial u)\det J\, du \wedge dw$ at $w = 0$, $A = J^\mathsf{T} A' J$, and $du' = \det(\partial U/\partial u)\, du$ on Z. So $\det A'^{-1/2} = \pm \det J \det A^{-1/2}$ and $\frac{\omega_0}{du'\wedge dw'} = \big(\det(\partial U/\partial u)\det J\big)^{-1}\frac{\omega_0}{du\wedge dw}$, and the product of these with du' is $\pm\det A^{-1/2}\frac{\omega_0}{du\wedge dw}\,du$: ν is defined up to sign. For $d = 0$ a point is regular exactly when the Hessian has rank $n - 1$, and an isolated point of the critical locus lies on no other component. □

Theorem 39.24 (A closed cycle on a source carries a solution). *As stated.*

Proof. (i) In the coordinates y the torus is, near each point, an open set of the vector space $\mathbb{C}^{\mathcal{E}}/\mathbb{C}\mathbf{1}$, in which $z+v$ has a meaning for small v. At $z \in Z^\circ$ call a real subspace V of dimension m of the tangent space a *descent subspace* when the real part of the Hessian of $-\log f$ is positive definite on it; then V meets the tangent space of Z only at 0, the Hessian vanishing there. The projection to the normal space $\mathbb{C}^m$, in coordinates in which the normal form is $\sum_i w_i^2$, maps V onto a real subspace V' with $V' \cap i\mathbb{R}^m = 0$, the form being negative on $i\mathbb{R}^m$; so $V' = \{x + iBx : x \in \mathbb{R}^m\}$ for a real matrix B, and the form has the real part $|x|^2 - |Bx|^2$ on it, positive definite exactly when $\|B\| < 1$. So the descent subspaces at z are the graphs over such V' of real linear maps into the tangent space of Z: a contractible set, whose oriented members form two contractible components, one for each sheet of ν. Over the compact $\gamma \subset \tilde{Z}^\circ$ there is therefore a continuous oriented choice $z \mapsto V_z$, and by Taylor's formula and compactness there are $r, c > 0$ with $|f(z+v)| \le |f_Z| e^{-c|v|^2}$ for $v \in V_z$, $|v| \le r$. Put $D_z = z + \{v \in V_z : |v| \le r\}$ and $N(\gamma) = \bigcup_{z\in\gamma} D_z$; as $\partial\gamma = 0$, $\partial N(\gamma)$ is the union of the boundaries of the discs, on which $|f| \le |f_Z| e^{-cr^2}$. For two choices over γ, or for $\gamma - \gamma' = \partial\Gamma$, the same construction over $\gamma \times [0,1]$ or over Γ, with discs of the same kind, gives a chain of dimension n whose boundary is the difference of the two chains together with a union of disc boundaries; the discs need not be affine, any smooth family of embedded discs tangent at z to a descent subspace serving as well for r small.

(ii) The integral over $N(\gamma)$ is the integral over $\gamma \times \{|v| \le r\}$ of the pull-back by $(z,v) \mapsto z+v$, $v \in V_z$. At each z, Laplace's method in v, uniform in z on the compact γ, expands the integral over D_z in powers of $1/k$ after the factor $f_Z^k k^{-m/2}$, with coefficients that are continuous d-forms along γ; integrating them over γ gives the $c_i(\gamma; g)$. The leading coefficient is $(2\pi)^{m/2} \det\big[H_z(\mathsf{f}_a, \mathsf{f}_b)\big]^{-1/2} g\, \omega_0(\,\cdot\,, \mathsf{f}_1, \dots, \mathsf{f}_m)$, H_z the Hessian of $-\log f$ and $\mathsf{f}_1, \dots, \mathsf{f}_m$ a basis of V_z, the square root fixed by the orientation; it does not change under a complex linear change of f, and V_z spans over $\mathbb{C}$ a complement of the tangent space of Z, which projects onto the normal space as the w-space does in coordinates (u, w), so it is $(2\pi)^{m/2} g\nu$ on the sheet. Where holomorphic normal slices $\{u = \text{const}\}$ cover Z°, take every D_z in the slice through z, a real descent disc there, which (i) allows. The integral over the slice at u has the phase $-\log f = -\log f_Z + \frac{1}{2} w^{\mathsf{T}} A(u) w + O(|w|^3)$ and the amplitude $g\,\omega_0/(du \wedge dw)$, and Laplace's method with the holomorphic parameter u gives $f_Z^k k^{-m/2} \sum_i k^{-i} a_i(u; g)$, where $a_i(u; g)$ is du times $(2\pi)^{m/2} \det A(u)^{-1/2}$ times a polynomial in finitely many w-derivatives at $w = 0$ of the amplitude and of the phase and in the entries of $A(u)^{-1}$. These coefficients are holomorphic in u, so each $a_i(\cdot\,; g)$ is a holomorphic d-form, $a_0(\cdot\,; g) = (2\pi)^{m/2} g\,\nu$, and $c_i(\gamma; g) = \int_\gamma a_i(\cdot\,; g)$.

(iii) By 38.2(ii), $(c_e^{(0)} + k c_e^{(1)} + \partial_{y_e}) g \cdot f^k \omega_0/dy = \partial_{y_e}\big(g f^k \omega_0/dy\big)$, so $(c_e^{(0)} + k c_e^{(1)} + \partial_{y_e}) g \cdot f^k \omega_0 = d\big(\iota_{\partial_{y_e}}(g f^k \omega_0)\big)$, the form being of top degree and ∂_{y_e} a constant field. By Stokes its integral over $N(\gamma)$ is an integral over $\partial N(\gamma)$, of modulus at most a constant times $|f_Z|^k e^{-kcr^2}$; so the expansion of every relation vanishes to all orders, and A_γ, extended $\mathbb{C}(k)$-linearly, vanishes on $\mathcal{L}$. The integral of $fg\, f^k \omega_0$ is that of $g\, f^{k+1} \omega_0$, so $A_\gamma(fg)(k) = A_\gamma(g)(k+1)$ after re-expansion, and A_γ is a solution of type $(f_Z, -\frac{m}{2} + \mathbb{Z})$. The forms $g f^k \omega_0$ are closed, so by Stokes on the chains of (i) homologous cycles give integrals differing by terms of modulus at most a constant times $|f_Z|^k e^{-kcr^2}$, hence the same expansion. The deck involution reverses the orientation of every disc. For an origin that is not integral the same construction runs with a branch of ω_0 carried along the chains, that is, for cycles with coefficients in the local system of the branches of ν.

(iv) A relation $\sum_a c_a \hat{A}_{\gamma_a} = 0$ with $c_a \in \mathbb{C}((1/k))$ not all zero, scaled so that the least order of the c_a is 0 with constant terms c_a^0 not all zero, gives at the leading order, applied to g_b, $(2\pi)^{m/2} \sum_a c_a^0 \int_{\gamma_a} g_b \nu = 0$ for every b, so $c^0 = 0$ by the determinant: a contradiction. The relations

over $\mathbb{C}$ are among them. □

Corollary 39.25 (A curve of native gauges: residues and periods). *As stated.*

Proof. The first homology of $\tilde{Z}^\circ$, a compact curve less finitely many points, is generated by small loops around the punctures and by the cycles of $\bar{Z}$, and A_γ depends only on the class of γ (Theorem 39.24(iii)). For the family $\alpha = \alpha_0 b^{\mathsf{v}} e^w$ the coordinates $(\log b, w)$ are linear in y, so dy is a constant multiple of $d\log b \wedge dw$. With an integral origin f, g and ω_0/dy are rational functions of α, and so are their derivatives in y, $\partial_{y_e} = \alpha_e \partial_{\alpha_e}$; their w-derivatives at $w = 0$ are constant combinations of these at $\alpha = \alpha_0 b^{\mathsf{v}}$, so rational in b, and so are the entries of $A(b)$ and $A(b)^{-1}$; the slices $\{b = \text{const}\}$ cover Z°, and the Laplace coefficients of Theorem 39.24(ii) are polynomials in these times $\det A(b)^{-1/2}$, so $a_i = r_i(b; g) \det A(b)^{-1/2}\, db/b$ with r_i rational. On the curve $Y^2 = \det A(b)$ these are meromorphic forms, and the integral over a small loop around a puncture is $2\pi i$ times the residue there. □

Theorem 39.26 (A native gauge of corank at most one). *As stated.*

Proof. The Hessian of $\log f$ at α_c has rank at least $n-2$. By the splitting lemma, the holomorphic Morse lemma in the directions where the Hessian is nondegenerate with the remaining coordinate as a parameter, there are coordinates (X, w) with $\log f = \log f(\alpha_c) - \frac{1}{2}\sum_i w_i^2 + R(X)$, $R(0) = R'(0) = 0$; when the Hessian is nondegenerate, X is one of the Morse coordinates and $R = -\frac{1}{2}X^2$. R does not vanish identically, as otherwise $\{w = 0\}$ would be a curve of native gauges through α_c. With $\mu + 1$ its order at 0, $R = cX^{\mu+1}(1 + O(X))$ with $c \neq 0$, and $X(1 + O(X))^{1/(\mu+1)}$ is a coordinate in which $R = cX^{\mu+1}$; $\mu = 1$ exactly when the Hessian is nondegenerate, and otherwise $R''(0) = 0$ and ∂_X spans the kernel.

(i) Let $\varrho_0, \dots, \varrho_\mu$ be the directions with $c\,\varrho^{\mu+1} < 0$, $\varrho_b = \varrho_0 \zeta^b$, $\zeta = e^{2\pi i/(\mu+1)}$; around them lie the sectors on which $\mathrm{Re}(cX^{\mu+1}) < 0$. For the path coming in along $\varrho_0\,\mathbb{R}_{>0}$ and going out along $\varrho_b\,\mathbb{R}_{>0}$,

$$\int X^j e^{cX^{\mu+1}} dX = \big(\varrho_b^{\,j+1} - \varrho_0^{\,j+1}\big) \frac{\Gamma\big(\frac{j+1}{\mu+1}\big)}{(\mu+1)|c|^{(j+1)/(\mu+1)}},$$

and these μ paths generate the homology of the plane relative to the part where $\mathrm{Re}(cX^{\mu+1}) < -1$. The $\mu \times \mu$ matrix of the numbers $\zeta^{b(j+1)} - 1$, $1 \le b \le \mu$, $0 \le j < \mu$, is invertible: its columns, extended by the entry 0 at $b = 0$, are the differences of the columns $l = j+1$ and $l = 0$ of the invertible matrix $(\zeta^{bl})_{0 \le b,l \le \mu}$. So there are complex combinations Γ_i of the paths with $\int_{\Gamma_i} X^j e^{cX^{\mu+1}} dX = \delta_{ij}$, $0 \le j < \mu$. Integration by parts gives $\int_\Gamma X^{j+\mu+1} e^{cX^{\mu+1}} dX = -\frac{j+1}{(\mu+1)c} \int_\Gamma X^j e^{cX^{\mu+1}} dX$, and $\int_\Gamma X^\mu e^{cX^{\mu+1}} dX = 0$, the integrand being a derivative; so $\int_{\Gamma_i} X^j e^{cX^{\mu+1}} dX = 0$ unless $j \equiv i \bmod \mu+1$. On the chain $C_i = D \times \Gamma_i$, D the real ball $|w| \le \varepsilon$ and Γ_i cut off at $|X| = \varepsilon$, the boundary lies where $|f| \le |f(\alpha_c)| e^{-\varepsilon'}$, and the relations and the shift hold up to exponentially smaller terms as in Theorem 39.24(iii). Expand the amplitude $\mathsf{a} = g\,\omega_0/(dX \wedge dw) = \sum \mathsf{a}_{j,\beta} X^j w^\beta$; after $X \mapsto k^{-1/(\mu+1)} X$ and $w \mapsto k^{-1/2} w$ the term (j, β) contributes $k^{-(n-2)/2 - |\beta|/2 - (j+1)/(\mu+1)}$ times a Gaussian moment, zero for odd $|\beta|$, times $\int_{\Gamma_i} X^j e^{cX^{\mu+1}} dX$, and the usual bounds of Laplace's method make the sum an asymptotic expansion. Only $j \equiv i \bmod \mu+1$ survive, the exponents are $-\frac{n-2}{2} - \frac{i+1}{\mu+1}$ less integers, and the leading one, $j = i$ and $\beta = 0$, has the coefficient $(2\pi)^{(n-2)/2} \mathsf{a}_{i,0}$. Since $0 < \frac{i+1}{\mu+1} < 1$, distinct i give distinct types; each $A_{c,i}$ is nonzero, an insertion with $\mathsf{a}_{i,0} \neq 0$ existing, and Lemma 39.3 gives the independence. For $\mu = 1$, $R = -\frac{1}{2}X^2$, the normalization $\int_{\Gamma_0} e^{-X^2/2} dX = 1$ makes Γ_0 the real line divided by $(2\pi)^{1/2}$, and C_0 is a steepest-descent disc divided by $(2\pi)^{1/2}$: $A_{c,0} = (2\pi)^{-1/2} A_c$.

(ii) In the coordinates y, ϕ is $y \mapsto M_\phi y$, linear, of finite order, fixing $\log \alpha_c$; it keeps $\log f$, so its Hessian and the kernel: $M_\phi \xi = \zeta_\phi \xi$ for ξ spanning the kernel, with ζ_ϕ a root of unity, and M_ϕ maps an invariant complement N of the kernel onto itself. In linear coordinates (X', w') along ξ and N the curve $\{\partial_{w'} \log f = 0\}$ through α_c is smooth and parametrized by X', the Hessian being nondegenerate on N; ϕ maps it onto itself by $X' \mapsto \zeta_\phi X'$, and $\log f$ on it is $\log f(\alpha_c)$ plus a function of order $\mu+1$ in X' with nonzero leading coefficient, the reduced function of the splitting lemma. Its invariance gives $\zeta_\phi^{\mu+1} = 1$.

As in Theorem 39.12(iii), $\phi^* \omega_0 = c_\phi \, \omega_0$ near α_c for a constant $c_\phi \neq 0$, so $A_{c,i}(g \circ \phi)$, the expansion over C_i of $(g \circ \phi) f^k \omega_0 = c_\phi^{-1} \phi^*(g f^k \omega_0)$, is c_ϕ^{-1} times the expansion over $\phi(C_i)$, a chain near α_c with its boundary where $|f|$ is smaller. The relative homology near α_c has rank μ over $\mathbb{C}$ with the basis $C_0, \dots, C_{\mu-1}$, so $A_{c,i} \circ \phi^* = \sum_{i'} \kappa_{i'} A_{c,i'}$. By (i) applied to the insertion $g \circ \phi$, $A_{c,i} \circ \phi^*$ has the type of $A_{c,i}$, and the $A_{c,i'}$ have distinct types, so $A_{c,i} \circ \phi^* = \kappa_i A_{c,i}$. The expansions depend only on the Taylor series of the insertion at α_c, and insertions realize every finite jet there, so the identity holds on formal power series at α_c. Let ℓ be the linear function of $y - \log \alpha_c$ that vanishes on N with $\ell(\xi) = 1$; then $\ell \circ \phi = \zeta_\phi \ell$. In the coordinates of (i), $\ell(X, 0) = \ell_1 X + O(X^2)$ with $\ell_1 \neq 0$, since ∂_X is along ξ at α_c, so the coefficient of X^i in $\ell^i \, \omega_0/(dX \wedge dw)$ at $w = 0$ is $\ell_1^i \, (\omega_0/(dX \wedge dw))(\alpha_c) \neq 0$, and $A_{c,i}(\ell^i) \neq 0$. Then $\kappa_i A_{c,i}(\ell^i) = A_{c,i}(\ell^i \circ \phi) = \zeta_\phi^i A_{c,i}(\ell^i)$ gives $\kappa_i = \zeta_\phi^i$. □

Corollary 39.27 (Signs at a centre). *As stated.*

Proof. The centre ray has origin 0 and direction $(\sigma \mathbf{1}; \boldsymbol{\sigma}, \boldsymbol{\sigma})$, so the Cremona is a symmetry by Proposition 39.11(ii). It fixes $\eta = \eta^{-1}$, and in the chart $\alpha = \eta e^y$ it is $y \mapsto -y$. (i) is Theorem 39.12(iii). In (ii), $\zeta = -1$, so $\mu + 1$ is even, and corank one makes $\mu \geq 2$, so $\mu \geq 3$; Theorem 39.26(ii) gives $A_{\eta,i} \circ \mathrm{cr}^* = (-1)^i A_{\eta,i}$. For a Cremona-invariant insertion g, $A_{\eta,i}(g) = A_{\eta,i}(g \circ \mathrm{cr}) = (-1)^i A_{\eta,i}(g)$ vanishes for odd i; for even i and an insertion g' with $A_{\eta,i}(g') \neq 0$, $\frac{1}{2}(g' + g' \circ \mathrm{cr})$ is invariant with the same value. The exponents are those of Theorem 39.26(i) at $\mu = 3$. □

Proposition 39.28 (Symmetries on the cycles of a source). *As stated.*

Proof. ϕ is an automorphism of X_F keeping f, so it maps the critical locus onto itself, sources onto sources, regular points onto regular points, and descent discs at z onto descent discs at $\phi(z)$, with their orientations; the sheet of ν at $\phi(z)$ that matches the image orientation defines $\tilde{\phi}$, and $\phi(N(\gamma)) = N(\tilde{\phi}_* \gamma)$ as oriented chains. With $f \circ \phi = f$ and $\varepsilon_\phi^2 = 1$, $(g \circ \phi) f^k \omega_0 = \varepsilon_\phi \, \phi^*(g f^k \omega_0)$, so $\int_{N(\gamma)} (g \circ \phi) f^k \omega_0 = \varepsilon_\phi \int_{N(\tilde{\phi}_* \gamma)} g f^k \omega_0$. On $\mathfrak{M}^G$, $A_\gamma = A_\gamma \circ e_G = |G|^{-1} \sum_\phi \varepsilon_\phi A_{\tilde{\phi}_* \gamma}$, which is linear in the cycle. Grouping $\phi \in G$ by the cosets ψG_Z, with $\varepsilon_{\psi\chi} = \varepsilon_\psi \varepsilon_\chi$ and $\widetilde{\psi\chi}_* = \tilde{\psi}_* \tilde{\chi}_*$, each coset contributes $\varepsilon_\psi A_{\tilde{\psi}_* z}$ with $z = \sum_{\chi \in G_Z} \varepsilon_\chi \tilde{\chi}_* \gamma$, zero when $[z] = 0$. □

Theorem 39.29 (What the invariant module sees at the high end). *As stated.*

Proof. For $\phi \in G$ and $\psi \in G_c$, $A_{c,i} \circ (\phi\psi)^* = A_{c,i} \circ \psi^* \circ \phi^* = \zeta_\psi^i A_{c,i} \circ \phi^*$ (Theorem 39.26(ii), and Theorem 39.12(iii) for $\mu = 1$), so

$$A_{c,i} \circ e_G = |G|^{-1} \sum_{\phi G_c} \Big(\sum_{\psi \in G_c} \zeta_\psi^i \Big) A_{c,i} \circ \phi^*.$$

When $\psi \mapsto \zeta_\psi^i$ is a nontrivial character of G_c its sum over G_c vanishes and $A_{c,i}$ vanishes on $\mathfrak{M}^G = e_G \mathfrak{M}$. Otherwise $A_{c,i} \circ e_G$ is $|G_c|/|G|$ times $A_{O,i} = \sum_{\phi G_c} A_{c,i} \circ \phi^*$, which is invariant, and

each $A_{c,i}\circ\phi^*$ is a constant multiple of an expansion over the chain $\phi(C_i)$ near $\phi(\alpha_c)$. The isolated native gauges are finitely many. Take an insertion with a Taylor jet at α_c that makes the leading coefficient of $A_{c,i}$ nonzero (Theorem 39.26(i)) and that vanishes to a high order at every other isolated native gauge; on it $A_{O,i}$ has that leading coefficient, so $A_{O,i}$ does not vanish on $\mathfrak{M}^G$, and the same insertions show that the $A_{O,i}$ of one type, over the orbits and the classes, are linearly independent over $\mathbb{C}$ on $\mathfrak{M}^G$, the solutions of one type at one point being a single $A_{c,i}$. Lemma 39.3 gives the bound. □

Definition 39.30 (Closings). As stated.

Proof. $\mathbb{C}[X_F]$ is spanned by the insertions $g=\alpha^u\prod_j K_j^{-a_j}\Psi_j^{-b_j}$ with $a_j,b_j\in\mathbb{N}$, products of the generators of 38.1, and for them $g\,f^{-j}\omega_0/dy=\alpha^{u-j\mathbf{m}_1+\mathbf{m}_0}\prod_l K_l^{js_{1l}-s_{0l}-a_l}\Psi_l^{jt_{1l}-t_{0l}-b_l}$, a Laurent polynomial when every exponent of a letter is nonnegative, which holds for large j as $s_{1l},t_{1l}\ge 1$; a finite sum takes the largest of the bounds. The function is homogeneous of degree 0, so its monomials α^u have $u_{\mathcal{E}}=0$, and on the chart $\alpha_{e_0}=1$ its constant term, the coefficient of the monomials with $u_e=0$ for $e\neq e_0$, is the coefficient of α^0, whatever e_0. On the chart $dy=\prod_{e\neq e_0}d\alpha_e/\alpha_e$, which gives the integral over the torus. □

Proposition 39.31 (One form on the orthant and on the torus). *As stated.*

Proof. On the orthant $f>0$ and $1/(f^{-1}-q)=f/(1-qf)$, so the first integral is the generating function of Theorem 38.14(ii) with $k_0=1$, which the origin 0 allows. The Laurent polynomial $f^{-1}=\alpha^{-\mathbf{m}_1}\prod_j K_j^{s_{1j}}\Psi_j^{t_{1j}}$ has nonnegative coefficients, so on the torus through $\alpha^\star$, $|f^{-1}(\alpha)|\le f^{-1}(\alpha^\star)=A$. For $|q|>A$ the series $1/(f^{-1}-q)=-\sum_{j\ge0}f^{-j}q^{-j-1}$ converges uniformly on that torus, and term by term $(2\pi i)^{-(n-1)}\oint f^{-j}\,dy$ is the constant term, $\oint\alpha^v\,dy=(2\pi i)^{n-1}$ for $v=0$ and 0 for the other monomials of degree 0. For every letter exponent positive this is $\mathsf{C}_j(1)$ (Definition 39.30, the origin form being dy). □

Proposition 39.32 (The constant terms of a centre ray and its signs). *As stated.*

Proof. By Definition 38.13, $f^{-1}=\prod_l\big(K_l(\alpha)K_l(\alpha^{-1})\big)^{\sigma_l}$, a Laurent polynomial with nonnegative coefficients, homogeneous of degree 0; at a sign $\eta^{-1}=\eta$, so $f^{-1}(\eta)=\prod_l K_l(\eta)^{2\sigma_l}$. On the chart $\alpha_{e_0}=1$ a monomial α^v, $v_{\mathcal{E}}=0$, takes at η the value $\prod_{e\neq e_0}\eta_e^{v_e}$, whose mean over the signs is 1 when every v_e, $e\neq e_0$, is even, and then $v_{e_0}=-\sum_{e\neq e_0}v_e$ is even too, and 0 otherwise. The constant term is the coefficient at $v=0$, one of the nonnegative coefficients summed. □

Theorem 39.33 (The closings are a solution). *As stated.*

Proof. By 38.2(ii), $c_e^{(0)}-j\,c_e^{(1)}=\partial_{y_e}\log\big(f^{-j}\omega_0/dy\big)$, so $\big(c_e^{(0)}-jc_e^{(1)}+\partial_{y_e}\big)g\cdot f^{-j}\omega_0/dy=\partial_{y_e}\big(gf^{-j}\omega_0/dy\big)$. For $j\ge j(g)$ the right side is ∂_{y_e} of a Laurent polynomial, which multiplies each monomial α^u by u_e and so has no constant term. $\mathsf{C}_j(fg)=\mathrm{CT}\,\big(gf^{-(j-1)}\omega_0/dy\big)=\mathsf{C}_{j-1}(g)$ for $j-1\ge j(g)$. An element of $\mathcal{L}$ is a finite sum $\sum r_{e,l}(k)\big(c_e^{(0)}+kc_e^{(1)}+\partial_{y_e}\big)h_{e,l}$, and V_{C} of it at an integer $k=-j$ off the poles of the $r_{e,l}$ with $j>j(h_{e,l})$ for all e,l, where the closings of $c_e^{(1)}h_{e,l}$ and of $(c_e^{(0)}+\partial_{y_e})h_{e,l}$ are defined, $c_e^{(0)}$, $c_e^{(1)}$ and ∂_{y_e} costing at most one power of each letter and f^{-1} supplying at least one, is $\sum r_{e,l}(-j)\,\mathsf{C}_j\big((c_e^{(0)}-jc_e^{(1)}+\partial_{y_e})h_{e,l}\big)=0$; so V_{C} is well defined on $\mathfrak{M}$ as a germ at $-\infty$. It is $\mathbb{C}(k)$-linear, and $V_{\mathsf{C}}(\mathrm{Sh}(g\otimes r))(k)=r(k+1)\,\mathsf{C}_{-k}(fg)=r(k+1)\,\mathsf{C}_{-k-1}(g)=\big(\varsigma V_{\mathsf{C}}(g\otimes r)\big)(k)$. Theorem 39.4(i) with $v(k)=\mathsf{C}_{-k}(\mathbf{b})$ reads $\mathsf{C}_{1-k}(\mathbf{b})=\mathbf{B}_{\mathbf{b}}(k)\,\mathsf{C}_{-k}(\mathbf{b})$, which at $k=-j$ is the stated identity, and the law of [1] applied to V_{C} gives $\sum_i p_i(k)\,\mathsf{C}_{-k-i}(1)=0$, at $k=-j$ the last statement. □

Proposition 39.34 (The closings are the top principal parts). *As stated.*

Proof. By 38.2(iii), $\langle g\rangle_k$ is a finite combination of periods P_F at data $(k\mathbf{m}_1+v; k\mathbf{s}_1+\mathbf{a}, k\mathbf{t}_1+\mathbf{b})$ on the balance wall. On the balance wall, where every proper wall has positive real part, 8.5(ii) and 8.7, $J_F=\Gamma(\kappa_{\mathcal{E}})P_F$, give

$$P_F(\mathbf{m};\mathbf{s},\mathbf{t})=\sum_{\pi}\int_{[0,1]^{n-1}}\prod_{l=2}^{n}q_l^{\kappa_{U_l}-1}\prod_j k_{j,\pi}(q)^{-s_j}\psi_{j,\pi}(q)^{-t_j}\,dq,$$

the limit $\kappa_{\mathcal{E}}\downarrow 0$ of the same identity with the factor $L_\pi^{-\kappa_{\mathcal{E}}}$, $L_\pi\in[1,n]$. The sector letters are positive on the closed cube, so the integrand is smooth in q and holomorphic in the exponents, and 8.4 continues each term meromorphically in the walls with the poles on $\kappa_{U_l}=-i$, $i\in\mathbb{N}$, as a finite sum of products of at most $n-1$ factors $(\kappa_{U_l}+i_l)^{-1}$ with functions holomorphic near the point. Along the ray every wall is $k\kappa_{1,U_l}$ plus a constant, with $\kappa_{1,U_l}>0$, so $\langle g\rangle_k$ is meromorphic in k with poles of order at most $n-1$.

For an integer $j\ge j(g)$ put $\epsilon=k+j$; then $\langle g\rangle_k=\langle P\rangle_\epsilon$ with the Laurent polynomial $P=gf^{-j}$, an identity for large $\operatorname{Re}k$ that continues. For a monomial α^u with $u\neq 0$ choose e with $u_e\neq 0$. The relation of 38.3 at the strength ϵ, with $c^{(0)}=0$ for the origin 0, holds for complex ϵ of large real part by the same integration by parts, the integrals converging absolutely there, and gives $u_e\langle\alpha^u\rangle_\epsilon=-\epsilon\,\langle c_e^{(1)}\alpha^u\rangle_\epsilon$, then as meromorphic functions; the right side has a pole of order at most $n-2$ at $\epsilon=0$. So $\epsilon^{n-1}\langle P\rangle_\epsilon$ and $\operatorname{CT}(P)\,\epsilon^{n-1}\langle 1\rangle_\epsilon$ have the same value at $\epsilon=0$. Finally $\langle 1\rangle_\epsilon=P_F(\epsilon\mathbf{m}_1;\epsilon\mathbf{s}_1,\epsilon\mathbf{t}_1)$ is the period of the question of the direction at the strength ϵ, whose walls are positive, and 17.5(i) gives $\epsilon^{n-1}\langle 1\rangle_\epsilon\to V_1$ as $\epsilon\downarrow 0$; the function being holomorphic at 0, that is its value. □

Proposition 39.35 (The low end, for every direction). *As stated.*

Proof. (i) For an integral origin $\kappa_{0,U}$ and $\kappa_U(g)$ are integers, so $\kappa_{1,U}k$ is one at such a pole; Proposition 38.5(ii) gives the rest.

(ii) The argument is that of the proof of Proposition 39.34, which uses of the direction only that $P=f^{-j}g$ is a Laurent polynomial. By Proposition 38.5(ii), $\langle g\rangle_k=\langle f^jP\rangle_k=\langle P\rangle_{k+j}$ as meromorphic functions; put $\epsilon=k+j$. For a monomial α^u, $u\neq 0$, take e with $u_e\neq 0$; with the origin 0, $(k\,c_e^{(1)}+\partial_{y_e})\alpha^u$ lies in $\mathcal{L}$ and its value vanishes identically, so $u_e\langle\alpha^u\rangle_\epsilon=-\epsilon\langle c_e^{(1)}\alpha^u\rangle_\epsilon$, whose pole at $\epsilon=0$ has order at most $n-2$. So $\epsilon^{n-1}\langle P\rangle_\epsilon$ and $\operatorname{CT}(P)\,\epsilon^{n-1}\langle 1\rangle_\epsilon$ have the same value at $\epsilon=0$. $\langle 1\rangle_\epsilon=P_F(\epsilon\mathbf{m}_1;\epsilon\mathbf{s}_1,\epsilon\mathbf{t}_1)$ (Lemma S20(iv)) is the period of the question of the direction (Definition 17.1) at the strength ϵ, whose walls are positive, and Theorem 17.5(i) gives $\epsilon^{n-1}\langle 1\rangle_\epsilon\to V_1$ as $\epsilon\downarrow 0$; $\epsilon^{n-1}\langle 1\rangle_\epsilon$ is holomorphic at 0, so that is its value. □

Corollary 39.36 (The law read at the low end). *As stated.*

Proof. The law says that $\sum_i p_i(k)f^i$ lies in $\mathcal{L}$, a finite sum $\sum r_{e,l}(k)\big(c_e^{(0)}+kc_e^{(1)}+\partial_{y_e}\big)h_{e,l}$. Integrating against $f^k dy$, by integration by parts for complex k of large real part, where the integrals converge absolutely, $\sum_i p_i(k)\langle 1\rangle_{k+i}=0$ there off the poles of the $r_{e,l}$, and so identically as meromorphic functions. At $k=-j$, $j\ge 0$, the term $i\le j$ has $\langle 1\rangle_{k+i}$ with a pole of order at most $n-1$ and the coefficient $V_1\mathsf{C}_{j-i}(1)$ of $(k+j)^{-(n-1)}$ (Proposition 39.34, $j(1)=0$), and $p_i(k)=p_i(-j)+O(k+j)$; the terms $i>j$ are holomorphic there, $k+i$ being near the positive integer $i-j$, where the walls are positive. So the coefficient of $(k+j)^{-(n-1)}$ is $V_1\sum_{i\le j}p_i(-j)\mathsf{C}_{j-i}(1)=0$, with $V_1>0$. On the centre ray $f=\prod_j\big(K_j(\alpha)K_j(\alpha^{-1})\big)^{-\sigma_j}$ (38.13). □

Definition 39.37 (The low-end coefficients). As stated.

Proof. By Proposition 38.5(ii) the value of 1 is meromorphic with a pole of order at most $n-1$ at 0, and by Proposition 39.35(ii) at $j=0$ the coefficient of k^{1-n} is V_1, a sum of products of positive walls. □

Corollary 39.38 (The low-end relation). *As stated.*

Proof. (i) By Proposition 38.5(ii) the value of $\sum_i p_i(k) f^i$, which is $\sum_i p_i(k)\langle 1\rangle_{k+i}$, vanishes identically, and every $\langle 1\rangle_{k+i}$ converges for $\operatorname{Re} k > 0$, the walls $(k+i)\kappa_{1,U}$ having positive real parts. Near $k=-j$, for $i \le j$, $\lim (k+j)^{n-1}\langle 1\rangle_{k+i} = V_1 \operatorname{CT}(f^{i-j})$ by Proposition 39.35(ii), while for $i > j$ the value $\langle 1\rangle_{k+i}$ is holomorphic at $k=-j$, $k+i$ being near a positive integer. Multiplying by $(k+j)^{n-1}$ and letting $k \to -j$ gives $V_1 \sum_{i \le \min(h,j)} p_i(-j) \operatorname{CT}(f^{i-j}) = 0$, and $V_1 > 0$.

(ii) Near $k=0$ the terms $i \ge 1$ are holomorphic, so $p_0(k)\langle 1\rangle_k = p_0(k)\, k^{1-n}\big(\mathsf{L}_0 + O(k)\big)$ is holomorphic at 0; as $\mathsf{L}_0 \ne 0$, p_0 vanishes to order at least $n-1$ there, and the value at 0 of $p_0(k)\langle 1\rangle_k$ is $[k^{n-1}]p_0 \cdot \mathsf{L}_0$.

(iii) With the origin 0, $c^{(0)} = 0$; at $k=0$ the certificate gives $\sum_i p_i(0) f^i = \sum_e \partial_{y_e} G_e(0)$, and $p_0(0) = 0$ by (ii), $n \ge 2$. The $G_e(0)$ are homogeneous of degree 0, so $\partial_{y_{e_0}} G_{e_0}(0) = -\sum_{e \ne e_0} \partial_{y_e} G_{e_0}(0)$ on the chart, and $\sum_e \partial_{y_e} G_e(0)$ is the divergence of the stated field in the coordinates y_e, $e \ne e_0$. By the divergence theorem its integral over the cube is the flux out of the cube, and as $R \to \infty$ the integral of $\sum_{i \ge 1} p_i(0) f^i$ over the cube tends to $\sum_{i \ge 1} p_i(0)\langle 1\rangle_i$, each f^i, $i \ge 1$, being integrable; by (ii) this is $-[k^{n-1}]p_0 \cdot \mathsf{L}_0$. □

Proposition 39.39 (The low-end coefficients are integrals over the faces of the sectors). *As stated.*

Proof. By Lemma S19 with $g=1$ and the origin 0, $\langle 1\rangle_k = \sum_\pi \int_{[0,1]^{n-1}} \prod_l q_l^{k\kappa_l - 1} \varphi_\pi^k \, dq$ for $\operatorname{Re} k > 0$. For h smooth on a neighbourhood of the cube, $\sum_A h_{[A]} = h$: the restriction of h to $\{q_l = 0,\ l \notin B\}$ enters with the coefficient $\sum_{A \supseteq B} (-1)^{|A \setminus B|}$, which is 1 for $B = \{2,\dots,n\}$ and 0 otherwise. $h_{[A]}$ depends on q_A only, and where $q_l = 0$, $l \in A$, the terms of B and $B \cup \{l\}$, $l \notin B$, cancel; so, one coordinate at a time (Hadamard's lemma), $h_{[A]} = \prod_{l \in A} q_l \cdot \tilde h_A$ with $\tilde h_A(q_A) = \int_{[0,1]^A} \big(\prod_{l \in A} \partial_{q_l}\big) h_{[A]}(t\, q_A)\, dt$ smooth, $t\, q_A = (t_l q_l)_{l \in A}$. With $h = \varphi_\pi^k$, holomorphic in k together with its q-derivatives,

$$\int_{[0,1]^{n-1}} \prod_l q_l^{k\kappa_l - 1} \big(\varphi_\pi^k\big)_{[A]}\, dq = \prod_{l \notin A} \frac{1}{k\kappa_l}\, J_{\pi,A}(k), \qquad J_{\pi,A}(k) = \int_{[0,1]^A} \prod_{l \in A} q_l^{k\kappa_l}\, \tilde h_A(q_A, k)\, dq_A,$$

and $J_{\pi,A}$ is holomorphic for $\operatorname{Re} k > -1/\max_l \kappa_l$. So $k^{n-1}\langle 1\rangle_k = \sum_\pi \sum_A k^{|A|} \prod_{l \notin A} \kappa_l^{-1} J_{\pi,A}(k)$ near 0, and $\mathsf{L}_i = \sum_\pi \sum_A \prod_{l \notin A} \kappa_l^{-1} [k^{i-|A|}] J_{\pi,A}$. The Taylor coefficients of $J_{\pi,A}$ at 0 are obtained by differentiating under the integral, the k-derivatives of the integrand being dominated on the cube by constants times $\prod_{l \in A} q_l^{-\varepsilon} |\log q_l|^N$ for $|k|$ small; by Leibniz's rule, with $\partial_k^m \varphi_\pi^k|_{k=0} = \log^m \varphi_\pi$, $\partial_k^\gamma q^{k\kappa}|_{k=0} = (\kappa \log q)^\gamma$ and $h \mapsto h_{[A]}$, $h \mapsto \tilde h_A$ linear and independent of k, the coefficient of $k^{i'}$ is the sum over $m + |\boldsymbol\gamma| = i'$ of the integrals of the statement, $\big(\log^m \varphi_\pi\big)_{[A]} / \prod_{l \in A} q_l$ being bounded. For $i=0$ only $A = \varnothing$ and $m=0$ enter, giving V_1; for $i=1$, $A=\varnothing$ with $m=1$ gives $\sum_\pi \prod_l \kappa_l^{-1} \log \varphi_\pi(0)$, the terms with $|A|=1$ and $m=0$ vanishing, $1_{[A]} = 0$; the constant terms of the sector letters are $\theta_{j,T^\pm_{j,\pi}}$ (Theorem 8.5(ii)). For $A = \{2,\dots,n\}$ the exponent m must be at least 1, so the whole cube enters only from $i=n$ on. □

Proposition 39.41 (The high end reads the formal type). *As stated.*

Proof. By Theorem 39.4(i), $\varsigma^{-1}v_V = \mathbf{B}v_V$. Divide by $\lambda^k k^\rho$: $\lambda^{-1}(1-\frac{1}{k})^\rho\big(a_0 + a_1(k-1)^{-1} + \cdots\big) = \big(\mathbf{B}_0 + \mathbf{B}_1 k^{-1} + \cdots\big)\big(a_0 + a_1 k^{-1} + \cdots\big)$. The order 0 gives $\lambda^{-1}a_0 = \mathbf{B}_0 a_0$, and the order 1 gives $\lambda^{-1}(a_1 - \rho a_0) = \mathbf{B}_0 a_1 + \mathbf{B}_1 a_0$; multiplied by w on the left, with $w\mathbf{B}_0 = \lambda^{-1}w$, it gives $-\lambda^{-1}\rho\, w a_0 = w\mathbf{B}_1 a_0$. For a simple eigenvalue the left and right eigenvectors pair to a nonzero number. A source whose solution does not vanish on $\mathfrak{N}$ has a solution vector of the form of the statement after an integral shift of ρ, the exponents of Theorems 39.24 and 39.26 being defined modulo $\mathbb{Z}$. □

Proposition 39.42 (The spectrum at infinite strength; changes of masters). *As stated.*

Proof. By Theorem 38.6(i) and (ii), $\hat{A}_c$ is $\mathbb{C}(k)$-linear, vanishes on $\mathcal{L}$, and $\hat{A}_c(g) = C_c\, g(\alpha_c) + O(1/k)$ with $C_c = (2\pi)^{(n-1)/2}(\omega_0/dv)(\alpha_c) \neq 0$, the same for every insertion g.

(i) Let $\sum_l \lambda_l(k)[b_l] = 0$ with $\lambda \neq 0$, and multiply λ by a power of k so that every λ_l is regular at ∞ and $\lambda(\infty) \neq 0$. Applying $\hat{A}_c$ and reading the coefficient of k^0 gives $C_c \sum_l \lambda_l(\infty)\, b_l(\alpha_c) = 0$ for every $\alpha_c \in C$; as the β_c span, $\lambda(\infty) = 0$, a contradiction. So the $[b_l]$ are a basis of $\mathfrak{N}$, and the matrix of Sh^{-1} on a basis is unique.

(ii) As in Theorem 39.4(i), $V[f^{-1}b_i] = \varsigma^{-1}V[b_i]$ and $V[f^{-1}b_i] = \sum_l \mathbf{B}_{il}V[b_l]$ for every solution V, whatever the independence of the b_l: $\varsigma^{-1}v_V = \mathbf{B}v_V$ with $v_V = (V[b_l])_l$. For $V = A_c$, of type $\big(f(\alpha_c), -\frac{n-1}{2} + \mathbb{Z}\big)$, the solution vector is $\lambda^k k^\rho\big(a_0 + O(1/k)\big)$ with $\lambda = f(\alpha_c)$, $\rho = -\frac{n-1}{2}$ and $a_0 = C_c\beta_c$, and ς^{-1} multiplies $\lambda^k k^\rho$ by $\lambda^{-1}\big(1 + O(1/k)\big)$ (Definition 39.2); the coefficient of $\lambda^k k^\rho$ in $\varsigma^{-1}v_V = \mathbf{B}v_V$ gives $\lambda^{-1}a_0 = \mathbf{B}(\infty)\, a_0$. Eigenvectors of distinct eigenvalues are independent, and a matrix with an eigenbasis taken among the β_c, $\alpha_c \in C$, is diagonalizable with the eigenvalues of those vectors, every β_c being an eigenvector.

(iii) $\mathrm{Sh}^{-1}\tilde{b}_i = \sum_l T_{il}(k-1)[f^{-1}b_l] = \sum_{l,l'} T_{il}(k-1)\mathbf{B}_{ll'}(k)[b_{l'}]$, which is $\sum_{i'} \tilde{\mathbf{B}}_{ii'}(k)\,\tilde{b}_{i'}$, and the solution vector of A_c on the $\tilde{b}_i$ is $T(k)\, v_{A_c}$, which satisfies $\varsigma^{-1}\tilde{v} = \tilde{\mathbf{B}}\tilde{v}$ by the same computation. $T(k)$ is invertible and $\hat{A}_c(b_1)$ has the nonzero constant term C_c, so $T(k)\big(\hat{A}_c(b_l)\big)_l = k^\nu\big(\tilde{\beta}_c + O(1/k)\big)$ with $\nu \in \mathbb{Z}$ and $\tilde{\beta}_c \neq 0$, and the computation of (ii) with $\rho = -\frac{n-1}{2} + \nu$ gives $\tilde{\mathbf{B}}(\infty)\tilde{\beta}_c = f(\alpha_c)^{-1}\tilde{\beta}_c$. Finally $T(k)\,\mathbf{B}(k)\,T(k)^{-1} = \big(T(k-1)T(k)^{-1}\big)^{-1}\tilde{\mathbf{B}}(k)$, which tends to $\tilde{\mathbf{B}}(\infty)$ when $T(k-1)T(k)^{-1} \to I$; it has the characteristic polynomial of $\mathbf{B}(k)$, whose coefficients therefore tend to those of $\tilde{\mathbf{B}}(\infty)$, and the roots of a monic polynomial depend continuously on its coefficients.

(iv) $T(k-1)\,\mathbf{B}(k)\,T(k)^{-1} = S(k-1)^{-1}S(k-1)\,\mathbf{B}_\circ\, S(k)^{-1}S(k) = \mathbf{B}_\circ$, and $T(k-1)T(k)^{-1} = S(k-1)^{-1}S(k) = \begin{bmatrix} 1 & 0 \\ -(k-1) & 1 \end{bmatrix}\begin{bmatrix} 1 & 0 \\ k & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}$. With $S(k)^{-1} = \begin{bmatrix} 1 & 0 \\ -k & 1 \end{bmatrix}$,

$$\mathbf{B}(k) = \begin{bmatrix} x_{11} - x_{12}k & x_{12} \\ (k-1)(x_{11} - x_{12}k) + x_{21} - x_{22}k & (k-1)x_{12} + x_{22} \end{bmatrix},$$

whose entry $(2,1)$ is $-x_{12}k^2 + O(k)$, whose trace is $x_{11} + x_{22} - x_{12}$ and whose determinant is $\det \mathbf{B}_\circ$; the trace of $\mathbf{B}_\circ$ is $x_{11} + x_{22}$. □

Definition 39.43 (Insertion lattice; native algebra; tame high end). As stated.

Proof. A is the local ring of $\mathbb{P}^1$ at ∞, a discrete valuation ring with the uniformizer k^{-1}. The critical locus is the zero set of the defects in X_F, so N_F is its ring of functions with the scheme structure of J_F. □

Theorem 39.44 (A tame high end). *As stated.*

Proof. (i) Λ_F is an A-submodule of the finite-dimensional $\mathbb{C}(k)$-space $\mathfrak{M}$ (Theorem 38.31(i)), and it spans $\mathfrak{M}$. Finitely generated and torsion-free over a discrete valuation ring, it is free, of rank $\dim \mathfrak{M}$; finitely many insertion classes generate it, and by Nakayama's lemma those among them whose images form a basis of $\Lambda_F/k^{-1}\Lambda_F$ form an A-basis. For $g \in \mathbb{C}[X_F]$ and $r \in A$, $\mathrm{Sh}^{\pm 1}[g \otimes r] = [f^{\pm 1} g \otimes r(k \pm 1)]$, with $f^{\pm 1} \in \mathbb{C}[X_F]$ (Lemma 38.2(ii); the letters are units on X_F) and $r(k \pm 1) \in A$. So $\mathrm{Sh}^{\pm 1}\,\Lambda_F \subseteq \Lambda_F$, and $\mathbf{B_b}$ and its inverse have entries in A.

(ii) For $g \in \mathbb{C}[X_F]$ and every mark e, $k^{-1}\big(c_e^{(0)} + k\, c_e^{(1)} + \partial_{y_e}\big) g \in \mathcal{L}$, and $c_e^{(0)} g$, $\partial_{y_e} g$ lie in $\mathbb{C}[X_F]$ (Lemma 38.2(i)). So

$$[c_e^{(1)}\, g] = -k^{-1}\big[c_e^{(0)}\, g + \partial_{y_e} g\big] \in k^{-1}\Lambda_F,$$

and J_F maps into $k^{-1}\Lambda_F$. The images of the insertions span $\Lambda_F/k^{-1}\Lambda_F$, since $A/k^{-1}A = \mathbb{C}$. If $[g] \in k^{-1}\Lambda_F$ then $[fg] = \mathrm{Sh}[g] \in (k+1)^{-1}\Lambda_F = k^{-1}\Lambda_F$, so the kernel is stable under f. For $r \in A$, $r(k-1) - r(k) \in k^{-1}A$, so Sh^{-1} reduces modulo $k^{-1}\Lambda_F$ to the multiplication by f^{-1}, whose matrix on the basis $[b_l]$ is $\mathbf{B_b}(\infty)$.

(iii) The critical locus has finitely many irreducible components Z, and f is constant on each, with a value $f_Z \neq 0$ (Definition 39.23). By the Nullstellensatz $\prod_Z (f^{-1} - f_Z^{-1})^N \in J_F$ for some N, so the eigenvalues of f^{-1} on every quotient of N_F by an f-stable subspace are among the f_Z^{-1}; with (ii) this is the first claim. Let $\lambda \neq 0$ be a root of the symbol of the law. The law has a formal solution $x = \lambda^k \varphi(k)$ in which φ is a product of a power k^ρ, a power of $\log k$, the exponential of a polynomial in $k^{1/p}$ of degree less than p, and a series in $k^{-1/p}$ (the formal reduction of linear difference equations of Birkhoff, Adams and Turrittin, which applies because the law has polynomial coefficients with $p_0 p_h \neq 0$). Then $V(\mathrm{Sh}^i[1]) = \varsigma^i x$ defines a solution of the cyclic submodule $\mathfrak{C}$ of $[1]$ in the sense of Definition 39.2, these formal series allowed. $\Lambda_F \cap \mathfrak{C}$ is an A-lattice in $\mathfrak{C}$, stable under $\mathrm{Sh}^{\pm 1}$ and saturated in Λ_F, so its reduction embeds in $\Lambda_F/k^{-1}\Lambda_F$, compatibly with f^{-1}. In a basis of $\Lambda_F \cap \mathfrak{C}$ the solution vector v has $v(k-1) = \mathbf{B}(k) v(k)$ with $\mathbf{B} \in GL(A)$ the matrix of Sh^{-1}, as in Theorem 39.4(i). Write $v = \lambda^k \varphi(k)\, w(k)$; dividing gives $\lambda^{-1} \frac{\varphi(k-1)}{\varphi(k)}\, w(k-1) = \mathbf{B}(k)\, w(k)$, and $\varphi(k-1)/\varphi(k) \to 1$. The leading term $a_0 \neq 0$ of w therefore has $\mathbf{B}(\infty) a_0 = \lambda^{-1} a_0$, as in Proposition 39.41, and λ^{-1} is an eigenvalue of f^{-1} on the reduction, so λ is a native value.

(iv) A nondegenerate native gauge is an isolated reduced point of the critical locus, the Jacobian of the defects being invertible there, so $\dim_{\mathbb{C}} N_F$ is their number. By Theorem 38.31(i) this number is at most $\dim \mathfrak{M} = \dim \Lambda_F/k^{-1}\Lambda_F$, so the surjection of (ii) is an isomorphism, and the multiplication by f^{-1} is diagonal on the idempotents of the points, with the eigenvalues $f(\alpha_c)^{-1}$. □

Theorem 39.45 (Separating the sources). *As stated.*

Proof. For new masters $\mathbf{b}' = T\mathbf{b}$, T invertible over $\mathbb{C}((1/k))$, $\mathrm{Sh}^{-1} b_i' = \sum_l T_{il}(k-1)\, \mathrm{Sh}^{-1} b_l$, so the matrix of Sh^{-1} becomes $T(k-1)\mathbf{B}(k)T(k)^{-1}$. After a constant change of basis, $\mathbf{B}_0 = \mathrm{diag}(\mathbf{B}_0^{(1)}, \dots, \mathbf{B}_0^{(s)})$ with $\mathrm{spec}\, \mathbf{B}_0^{(a)} = \Lambda_a$. Seek $T = I + \sum_{i \geq 1} T_i k^{-i}$ and a block diagonal $C = \sum_{i \geq 0} C_i k^{-i}$, $C_0 = \mathbf{B}_0$, with $T(k-1)\mathbf{B}(k) = C(k)T(k)$. Write $T(k-1) = \sum_i \tilde{T}_i k^{-i}$, where $\tilde{T}_i - T_i$ depends on $T_1, \dots, T_{i-1}$ only. The coefficient of k^{-i} is

$$T_i \mathbf{B}_0 - \mathbf{B}_0 T_i = C_i - \mathbf{B}_i + E_i, \qquad E_i = \sum_{0<a<i} \big(C_a T_{i-a} - \tilde{T}_a \mathbf{B}_{i-a}\big) - (\tilde{T}_i - T_i)\mathbf{B}_0,$$

with E_i known from the lower orders. Take C_i the block diagonal part of $\mathbf{B}_i - E_i$, the diagonal blocks of T_i zero, and the block (a,b), $a \neq b$, of T_i the solution X of $X\mathbf{B}_0^{(b)} - \mathbf{B}_0^{(a)} X = (E_i - \mathbf{B}_i)^{(ab)}$, unique since the spectra are disjoint. The blocks of the new masters span the $\hat{\mathfrak{N}}_a$.

If $\bigoplus_a \hat{\mathfrak{N}}'_a$ is another such decomposition, the inclusion of $\hat{\mathfrak{N}}'_a$ followed by the projection onto $\hat{\mathfrak{N}}_b$, $b \neq a$, commutes with the shift; in bases it is a matrix X over $\mathbb{C}((1/k))$ with $C'^{(a)}(k)X(k) = X(k-1)C^{(b)}(k)$. If $X \neq 0$, $X = k^v(X_0 + O(k^{-1}))$ with $X_0 \neq 0$, and the leading order $C_0'^{(a)}X_0 = X_0 C_0^{(b)}$ forces $X_0 = 0$, the spectra being disjoint. So $\hat{\mathfrak{N}}'_a \subseteq \hat{\mathfrak{N}}_a$ for every a, and the sums being direct and equal to the whole space, $\hat{\mathfrak{N}}'_a = \hat{\mathfrak{N}}_a$. A solution of type $(\lambda, \rho + \mathbb{Z})$, extended $\mathbb{C}((1/k))$-linearly and restricted to $\hat{\mathfrak{N}}_b$, has in the basis of $\hat{\mathfrak{N}}_b$ the solution vector $\lambda^k k^\rho w$; if it is not zero, $w = k^{-v}(w_0 + \cdots)$ with $w_0 \neq 0$, and the first statement of Proposition 39.41, whose proof uses only the expansion of the matrix at ∞, gives $C^{(b)}(\infty)w_0 = \lambda^{-1}w_0$, so $\lambda^{-1} \in \Lambda_b$. A symmetry commutes with the shift, so it carries the decomposition to one with the same property, the matrix of Sh^{-1} on the image basis being the same; by uniqueness it maps each $\hat{\mathfrak{N}}_a$ onto itself. □

Corollary 39.46 (Gluing at the two ends). *As stated.*

Proof. With $\mathcal{S}_\mathrm{f}$ the formal solutions in $\mathcal{S}$, $\mathrm{Ann}(\mathcal{S}) \cap \mathfrak{N} = \mathrm{Ann}(\mathcal{S}_\mathrm{f}) \cap \mathfrak{N}_\mathsf{C}$, a submodule of $\mathfrak{N}_\mathsf{C}$ (Theorem 39.4(ii)), and Theorem 39.4(iii) applies. If $\mathfrak{N}$ is irreducible and V_C does not vanish on it, $\mathfrak{N}_\mathsf{C}$ is a submodule other than $\mathfrak{N}$, hence 0. If $\mathfrak{m}$ formal solutions are linearly independent over $\mathbb{C}$ on $\mathfrak{N}$, type by type, Lemma 39.3 makes their normalizations $\mathfrak{m}$ independent linear forms on $\mathfrak{N} \otimes \mathbb{C}((1/k))$, of dimension $\mathfrak{m}$, so no nonzero element of $\mathfrak{N}$ is annihilated by all of them. □

Definition 39.47 (The pencil module; singular values; vanishing ranks). As stated.

Proof. X_F is a smooth affine variety of dimension $n-1$ with the global coordinates y_e, $e \neq e_0$, and ω_0/dy is a unit of $\mathbb{C}[X_F]$, the origin being integral; so the top forms are the $h\,\omega_0$ and the forms of degree $n-2$ are spanned by the $\iota_{\partial_{y_e}}(h\,\omega_0)$. Since $d\,\iota_{\partial_{y_e}}(h\omega_0) = L_{\partial_{y_e}}(h\omega_0) = (c_e^{(0)}h + \partial_{y_e}h)\,\omega_0$ by Lemma 38.2(ii) at $k=0$, and $d\varphi \wedge \iota_{\partial_{y_e}}(h\omega_0) = (\partial_{y_e}\varphi)\,h\,\omega_0$, the image of $\iota_{\partial_{y_e}}(h\omega_0)\partial^j$ under the differential is $R(e,h,j)$. The operators ∂ and $\tau(\eta\partial^j) = \varphi\eta\partial^j - j\eta\partial^{j-1}$ on $\Omega^\bullet[\partial]$ commute with $D' = d - \partial\,d\varphi\wedge$: for τ,

$$\tau D'(\eta\partial^j) - D'\tau(\eta\partial^j) = (j+1)\,d\varphi\wedge\eta\,\partial^j - d\varphi\wedge\eta\,\partial^j - j\,d\varphi\wedge\eta\,\partial^j = 0,$$

and $\partial\tau - \tau\partial = 1$. The operator τ is invertible on $\Omega^\bullet[\partial]$: on an element of top degree N in ∂ the equations $\varphi\sigma_j - (j+1)\sigma_{j+1} = \tau_j$ are solved from $j = N$ down, φ being a unit. So $t = \tau$ and $\partial_t = \partial$ make the cohomology a $\mathcal{D}$-module. The fibre integrals of $h\,\omega_0\,\partial^j$ are those of $h\,\omega_0/d\varphi$ differentiated j times, and they kill the relations by Stokes's theorem on the fibres. For $N = \mathcal{D}/\mathcal{D}Q$ the characteristic cycle is the divisor of the principal symbol of Q, whose part over $t_0 \in \mathbb{C}^\times$ is the order of vanishing of the principal coefficient there. □

Proposition 39.48 (The ray is the moment side of its pencil). *As stated.*

Proof. By Lemma 38.2(ii), $\partial_{y_e}\varphi = -\varphi\,c_e^{(1)}$, and $\mathrm{Sh}[\varphi x] = [x]$. So

$$\Theta\big((h\,\partial_{y_e}\varphi)\partial^{j+1}\big) = (k)_j(k+j)\,\mathrm{Sh}^{j+1}[h\,\partial_{y_e}\varphi] = (k)_j\,\mathrm{Sh}^j\left(k\,\mathrm{Sh}[h\,\partial_{y_e}\varphi]\right) = -(k)_j\,\mathrm{Sh}^j\left(k\,[c_e^{(1)}h]\right),$$

and $\Theta(R(e,h,j)) = (k)_j\,\mathrm{Sh}^j\left[(c_e^{(0)} + k\,c_e^{(1)} + \partial_{y_e})h\right] = 0$. Next $\mathrm{Sh}^j[\varphi h] = \mathrm{Sh}^{j-1}[h]$ gives

$$\Theta(t\cdot h\partial^j) = \big((k)_j - j\,(k)_{j-1}\big)\,\mathrm{Sh}^{j-1}[h] = (k-1)_j\,\mathrm{Sh}^{j-1}[h] = \mathrm{Sh}^{-1}\,\Theta(h\partial^j),$$

and $\Theta(h\partial^{j+1}) = (k)_j(k+j)\,\mathrm{Sh}^{j+1}[h] = k\,\mathrm{Sh}\;\Theta(h\partial^j)$. So $t\partial_t \mapsto \mathrm{Sh}^{-1}\,k\,\mathrm{Sh} = k-1$, Θ is $\mathbb{C}[t\partial_t]$-linear for $k = t\partial_t + 1$, and it extends to $\mathbb{C}(k) \otimes_{\mathbb{C}[t\partial_t]} \mathcal{G}_F$, on which t acts invertibly and semilinearly,

$t\,r(k) = r(k-1)\,t$. Conversely $[h \otimes r(k)] \mapsto r(t\partial_t + 1)\,h\partial^0$ is well defined on $\mathfrak{M}$: in $\mathcal{G}_F$, $(t\partial_t + j)(x\partial^{j-1}) = (\varphi x)\partial^j$, so $(\varphi x)\partial = (t\partial_t + 1)(x\partial^0)$ and

$$R(e,h,0) = \big(\partial_{y_e} h + c_e^{(0)} h\big)\partial^0 + (t\partial_t + 1)\big(c_e^{(1)} h\,\partial^0\big),$$

the image of $(c_e^{(0)} + k\,c_e^{(1)} + \partial_{y_e})h$; and $t\cdot(fg)\partial^0 = g\partial^0$, so $\mathrm{Sh} = t^{-1}$ is respected. The two maps are inverse: $(t\partial_t+1)(t\partial_t+2)\cdots(t\partial_t+j)\big(f^j h\,\partial^0\big) = h\partial^j$ by the identity above applied j times, which is the image of $\Theta(h\partial^j) = (k)_j[f^j h]$. The moments: for a real origin the orthant maps onto $[A,\infty)$ under φ (Theorem 38.14(i)), so the coarea formula gives $\langle h\rangle_k = \int_{\mathbb{R}^{\mathcal{E}}_{>0}/\mathbb{R}_{>0}} h\,\varphi^{-k}\omega_0 = \int_A^\infty t^{-k} P_h(t)\,dt$ for all large k; and $\int t^{-k}\partial_t^j P_h\,dt = (k)_j \int t^{-k-j} P_h\,dt$ for the distributional derivatives of P_h extended by 0 below A, which matches $\Theta(h\partial^j) = (k)_j\,\mathrm{Sh}^j[h]$. □

Theorem 39.49 (The symbol is the principal symbol of the pencil). *As stated.*

Proof. $\mathcal{D}$ embeds in $\mathbb{C}(k)\langle \mathrm{Sh}^{\pm 1}\rangle$ by $t \mapsto \mathrm{Sh}^{-1}$, $\partial_t \mapsto k\,\mathrm{Sh}$, which respects $[\partial_t, t] = 1$ since $k-(k-1) = 1$; its image is $\mathbb{C}[k]\langle \mathrm{Sh}^{\pm 1}\rangle$, and $t^i\partial_t^j \mapsto (k-i)_j\,\mathrm{Sh}^{j-i}$, of the top degree j in k with the leading coefficient 1. For an element $\sum_i r_i(k)\,\mathrm{Sh}^i$ with $r_i \in \mathbb{C}[k]$ call $\sum_i [k^\delta] r_i\,\lambda^i$ its symbol, δ the largest degree; symbols multiply, since $\mathrm{Sh}^i\,r(k) = r(k+i)\,\mathrm{Sh}^i$ keeps the leading coefficient of r. For $Q \in \mathcal{D}$ of order m with the principal coefficient $a_m(t) = \sum_i a_{im} t^i$ the symbol of its image is $\sum_i a_{im}\lambda^{m-i} = \lambda^m a_m(1/\lambda)$; and $A_L \mapsto L$, since $t\partial_t + 1 \mapsto k$ and $t^{-i} \mapsto \mathrm{Sh}^i$. So the principal coefficient of A_L is $t^d\chi(1/t)$.

(i) $L[1] = 0$ in $\mathfrak{M} = \mathbb{C}(k) \otimes \mathcal{G}_F$ (Proposition 39.48), so $A_L \cdot 1$ is $\mathbb{C}[t\partial_t]$-torsion in $\mathcal{G}_F$ and some $c(t\partial_t)A_L$ kills 1. If $Q\cdot 1 = 0$ in $\mathcal{G}_F$, the image of Q annihilates $[1]$ in $\mathfrak{M}$; multiplied by a power of Sh it has only nonnegative powers, and division by L leaves a remainder of order less than h that annihilates $[1]$, hence 0, the classes $[1], \ldots, \mathrm{Sh}^{h-1}[1]$ being independent (Definition 39.1). So the image of Q is $\mathrm{Sh}^{-N}\,Q'L$, and χ divides its symbol.

(ii) $\mathcal{D}_F[1] = \mathcal{D}/I$ with I the annihilator of 1; it is holonomic, a cyclic module on a curve with $I \ni c(t\partial_t)A_L \neq 0$. It is a connection near t_0 exactly when I contains an element whose principal coefficient does not vanish at t_0: its characteristic variety is the common zero set of the principal symbols of the elements of I, and a holonomic module on a curve is a connection near t_0 exactly when that variety meets the cotangent line of t_0 only at 0. By (i) every principal coefficient in I vanishes where $\chi(1/t)$ does, and $c(t\partial_t)A_L$ has the principal coefficient $c_* t^{\deg c + d}\chi(1/t)$, c_* the leading coefficient of c, which vanishes on $\mathbb{C}^\times$ nowhere else.

(iii) The characteristic cycle of $\mathcal{D}/\mathcal{D}c(t\partial_t)A_L$ is the divisor of its principal symbol, whose part over $t_0 \in \mathbb{C}^\times$ has the multiplicity of $1/t_0$ as a root of χ. The kernel $I/\mathcal{D}c(t\partial_t)A_L$ of the surjection onto $\mathcal{D}_F[1]$ becomes 0 over $\mathbb{C}(k)$, where both ideals generate the ideal of L, so it is $\mathbb{C}[t\partial_t]$-torsion: a quotient of a finite sum of modules $\mathcal{D}/\mathcal{D}q(t\partial_t)$, $q \neq 0$, whose principal symbols $q_*(t\xi)^{\deg q}$ do not vanish over $\mathbb{C}^\times$ off the zero section. Characteristic cycles add along exact sequences and are nonnegative, so the kernel contributes nothing over t_0, and $r_{t_0}(\mathcal{D}_F[1])$ is that multiplicity.

(iv) On a neighbourhood of t_0 on which $\mathcal{G}_F$ is a connection, a coherent module over the holomorphic functions, its $\mathcal{D}$-submodule $\mathcal{D}_F[1]$ is coherent as well, so a connection. □

Lemma 39.50 (An orbit counts at most once). *As stated.*

Proof. G acts on $\Omega^\bullet[\partial]$ by pullback, commuting with the differential and with t and ∂_t, since it preserves φ; so it acts on $\mathcal{G}_F$ by $\mathcal{D}$-linear maps, and $\mathcal{G}_F = \bigoplus_\psi \mathcal{G}_F^\psi$ over the irreducible characters, G being finite. The class $1 = [\omega_0]$ spans a line of the character χ_0, so $\mathcal{D}_F[1] \subseteq \mathcal{G}_F^{\chi_0}$, and characteristic cycles being additive and nonnegative, $r_{t_0}(\mathcal{D}_F[1]) \le r_{t_0}(\mathcal{G}_F^{\chi_0})$. The vanishing rank of a regular holonomic module on a curve is the dimension of its vanishing cycles (the index theorem of

Kashiwara on curves; $\mathcal{G}_F$ is regular holonomic as the direct image of $\mathcal{O}_{X_F}$ under a regular function on a smooth affine variety, by the theorems of Bernstein and Kashiwara on direct images and the regularity theorem of Deligne). Over a small disc about t_0 the only critical points of φ are the native gauges of the value $1/t_0$, nondegenerate, and the absence of asymptotic native gauges makes φ a locally trivial fibration near infinity over the disc (Rabier's theorem, as in the proof of Theorem 39.51); so the vanishing cycles of $\mathcal{G}_F$ at t_0 are the direct sum over these points p of one line each, spanned by the image of any top form that does not vanish at p (the holomorphic Morse lemma and the description of the vanishing cycles of a nondegenerate critical point), for instance ω_0, which is a unit times dy. G permutes these lines. The stabilizer G_p acts on the line of p through its action on the image of $[\omega_0]$, that is by $\chi_0|_{G_p}$, so the lines of the orbit of p form the induced representation $\operatorname{Ind}_{G_p}^{G}(\chi_0|_{G_p})$, which contains χ_0 exactly once by Frobenius reciprocity. So the χ_0-part of the vanishing cycles has the dimension of the number of orbits. □

Theorem 39.51 (The symbol is read off the sources). *As stated.*

Proof. By Theorem 39.49(ii) and (iv) a nonzero root λ makes $t_0 = 1/\lambda$ a singular value of $\mathcal{G}_F$. Since every letter has a positive exponent, $\varphi = \alpha^{-\mathbf{m}_1} \prod_j K_j^{s_{1j}} \Psi_j^{t_{1j}}$ is a regular function on the torus T and $X_F = \varphi^{-1}(\mathbb{C}^\times)$. Two results finish the argument.

(a) Over a disc on which $\varphi : X_F \to \mathbb{C}^\times$ is a locally trivial fibration, $\mathcal{G}_F$ is a connection, the local system of the top cohomology of the fibres (Grothendieck's comparison theorem for the algebraic de Rham complex of the fibres, with the base change of the direct image along a smooth affine morphism, which apply because X_F is smooth and affine and φ is regular).

(b) In the logarithmic coordinates T is $\mathbb{C}^{n-1}/2\pi i\mathbb{Z}^{n-1}$ with a complete flat metric, and a map of a complete Finsler manifold to $\mathbb{C}$ is a locally trivial fibration over every value that is neither a critical value nor a limit of the map along a sequence leaving every compact set with the norm of the differential tending to 0 (Rabier's theorem on Ehresmann fibrations, which applies because the metric is complete).

A critical value of φ in $\mathbb{C}^\times$ is the reciprocal of a native value, since $d\log\varphi = -c^{(1)}$. The norm of $d_y\varphi = -\varphi\, c^{(1)}$ tends to 0 along a sequence with $\varphi \to t_0 \neq 0$ exactly when $c^{(1)} \to 0$, so a limit of the second kind is the reciprocal of an asymptotic native value. For the last claim, points converging to a point of the orbit of that flag have the bunch scale $\rho \to 0$ and their positions converging in $T_B \times T_R$, which is the setting of Proposition 38.26; its proof uses only that the defects tend to 0, for complex perturbations, and gives the values of (ii) and (iii) there. □

Corollary 39.52 (Where the spectrum is native). *As stated.*

Proof. (i) is Theorem 39.51. (ii) By Proposition 38.30(i) an asymptotic native gauge has a limit point at which two factors of $\Pi_{\mathfrak{f}}$ vanish, so two zero sets meet, or one factor vanishes with a singular zero set; both are excluded. (iii) is Proposition 38.26(i) with its first claims, $\bar{Q}$ being $\Psi^{[0]}$ up to a monomial (Proposition 38.25): a factor of $K^{[0]}$ and a factor of $\Psi^{[0]}$ vanishing together give $Q_1 = 0$ at the limit, against $\lambda^{-1} = Q_1 \neq 0$. □

Theorem 39.53 (Uncarried letters). *As stated.*

Proof. The proof of Theorem 39.49 uses only that φ is a unit of $\mathbb{C}[X_F]$, which holds; so a root is $1/t_0$ for a singular value t_0 of $\mathcal{G}_F$, and by (a) in the proof of Theorem 39.51 the map $\varphi : X_F \to \mathbb{C}^\times$ is not a locally trivial fibration over any disc about t_0. The map φ is regular on X', and the pair (X', Y) with the Whitney stratification of Y and the open stratum X_F is a stratified space on

which φ is a stratified map. Over a value that is neither a critical value of φ on a stratum nor a limit of φ along a sequence on a stratum leaving every compact set of T with the norm of the differential along the stratum tending to 0, the stratified map is locally trivial compatibly with the strata (Thom's first isotopy lemma, with the condition at infinity of Rabier's kind for stratified maps, which applies on T with its complete flat metric); then the fibres of X' and of Y are trivial as a pair, and those of $X_F = X' \setminus Y$ are trivial. So t_0 is a value of one of the three kinds, with $d\log f = c^{(1)}$ on X_F and its restriction on the strata. □

Proposition 39.54 (The far end of the pencil). *As stated.*

Proof. For real $t > A$ the orthant fibre $\{\varphi = t\} \cap \mathbb{R}^{\mathcal{E}}_{>0}$ is compact, φ tending to ∞ at the ends of the orthant (Theorem 38.14(i)), so P is the fibre integral of $\omega_0 = dy$ over a family of cycles, a solution of $\mathcal{D}_F[1]$, which continues along every path that avoids the singular values. The point $t = \infty$ is a regular singular point of $\mathcal{D}_F[1]$ (Deligne's regularity theorem for the Gauss–Manin connection, φ being regular on a smooth variety), so for large real t

$$P(t) = \sum_a \sum_{l \geq 0} c_{a,l}\, t^{-a-1} \frac{(\log t)^l}{l!},$$

a finite sum over classes of exponents a modulo $\mathbb{Z}$, each with convergent series in $1/t$. In the Mellin transform of Proposition 39.48, $\int_A^\infty t^{-k} t^{-a-1} (\log t)^l / l!\, dt$ has at $k = -a$ a pole whose top term is $(k+a)^{-l-1}$, the lower terms carrying powers of $\log A$; so the pole of the highest order of $\langle 1 \rangle_k$ at $k = -a$ is read from the coefficient with the largest l. The poles of $\langle 1 \rangle_k$ have order at most $n-1$ (Proposition 38.5(ii)), so $l \leq n-2$, and at $k = -j$, $j \in \mathbb{N}$, the coefficient of $(k+j)^{-(n-1)}$ is $V_1\, \mathsf{C}_j(1)$ (Proposition 39.35(ii)), so $c_{j,n-2} = V_1 \mathsf{C}_j(1)$ for the integral exponents. One turn about $t = \infty$ moves $\log t$ by $\pm 2\pi i$ and multiplies t^{-a} by a root of unity, the constant one for integral a; on the integral exponents $(T_\infty - 1)^{n-2}$ keeps exactly the top power of $\log t$, with the factor $(\pm 2\pi i)^{n-2}$, which gives the identity. Since $\mathsf{C}_0(1) = 1$ and $V_1 > 0$, $T \neq 0$, so the cyclic span of P under T_∞ has a Jordan block of size at least $n-1$ for the eigenvalue 1, and at most $n-1$ by the monodromy theorem for the cohomology of degree $n-2$ of the fibres (Landman's theorem, the fibres being affine of dimension $n-2$); $(T_\infty - 1)T = 0$ because T has no logarithm, so T spans the invariant line of the block. □

Definition 39.55 (The homogeneous reading; the data of a vertex). As stated.

Proof. The marker g_v of the parent edge is a mark of the core $\mathcal{H}_{v,j}$, and no mark of a core is a loop or a coloop (Definition 21.1), so its hinge minors are tables with the inherited weights (Definition 7.3). The coordinates of λ_e are Laurent monomials in α_e, among them α_e and α_e^{-1}, so λ_e is a closed embedding onto the curve $c_j = c'_j = 1$, $d_j = \alpha_e$, $d'_j = \alpha_e^{-1}$, $\mu = \alpha_e^{p_e}$; the coordinates of N_v and of R_o are polynomials, the last one mapping the tori of the μ_c to $\mathbb{C}^\times$. The reading is multilinear, and $\prod_c u_c \cdot \sum_T \theta_T \prod_{c \in T} (w_c/u_c) = \mathcal{H}^{\hom}(\mathbf{u}, \mathbf{w})$ where every $u_c \neq 0$. □

Theorem 39.56 (The pencil along a hinge tree). *As stated.*

Proof. (i) Induction from the marks up. Fix $v \neq o$ and j, and write $\mathcal{H} = \mathcal{H}_{v,j}$, $g = g_v$ and $\mathcal{A} = \mathcal{A}_{v,j}$; for a child c let $\mathcal{A}_c$ be its subtree cell, with the hinge g_c, or for a mark e the cell $\binom{\{e, g_e\}}{1}$ that leaves it in place. By Definition 23.15 $\mathcal{A} = \mathcal{H}\langle \mathcal{A}_c \rangle$ with g not substituted, so its bases are the sets $\bigsqcup_c X_c \cup (T \cap \{g\})$, T a basis of $\mathcal{H}$, with X_c a basis of $\mathcal{A}_c \setminus g_c$ when $c \in T$ and of $\mathcal{A}_c / g_c$ when $c \notin T$, of the weight $\theta_T^{\mathcal{H}} \prod_{c \in T} \theta_{X_c} \prod_{c \notin T} \theta_{X_c + g_c}$ in each letter (Definition 21.1). The bases avoiding

g are those of $\mathcal{A}\setminus g$, with T running over the bases of $\mathcal{H}\setminus g$, and the bases containing g, less g, are those of $\mathcal{A}/g$, with $T-g$ running over the bases of $\mathcal{H}/g$, of the weight $\theta^{\mathcal{H}}_T$ (Definition 7.3). For each T the sum of the monomials of these bases factors child by child, so

$$K_{\mathcal{A}\setminus g}=\sum_{T\in\mathcal{H}\setminus g}\theta_T\prod_{c\in T}K_{\mathcal{A}_c\setminus g_c}\prod_{c\notin T}K_{\mathcal{A}_c/g_c}=(\mathcal{H}\setminus g)^{\hom}\big((K_{\mathcal{A}_c/g_c},K_{\mathcal{A}_c\setminus g_c})_c\big),$$

and $K_{\mathcal{A}/g}=(\mathcal{H}/g)^{\hom}$ of the same pairs; the same holds for K^Ψ at α^{-1}, with the weights of Ψ. A mark left in place has $K_{\mathcal{A}_e\setminus g_e}=\alpha_e$ and $K_{\mathcal{A}_e/g_e}=1$, the pair of λ_e, and the same at α^{-1}; the last coordinates multiply. At the root the same computation over the bases of $\mathcal{H}_{o,j}$ gives K_j, and $K_j^\Psi(\alpha^{-1})=\alpha^{-\mathcal{E}}\Psi_j(\alpha)$. So

$$f^{-1}=\alpha^{-\mathbf{m}_1}\prod_j K_j^{s_{1j}}\Psi_j^{t_{1j}}=\alpha^{|\mathbf{t}_1|\mathbf{1}-\mathbf{m}_1}\prod_j K_j^{s_{1j}}\big(K_j^\Psi(\alpha^{-1})\big)^{t_{1j}}=R_o\circ\prod_c\lambda_c,$$

with $\alpha^{|\mathbf{t}_1|\mathbf{1}-\mathbf{m}_1}=\prod_e\alpha_e^{p_e}$; and the letters vanish nowhere exactly on the preimage of U_o, the monomial $\alpha^{\mathcal{E}}$ being a unit of the torus.

(ii) Every map here is a morphism of smooth affine varieties: λ_e is a closed embedding, N_v is polynomial, and U_o, the complement of a hypersurface, is affine. For such a morphism the direct image of a holonomic module is holonomic and has no cohomology in positive degrees (a morphism of affine varieties is the closed embedding of its graph followed by a projection; the direct image under the first is exact, and under the second it is computed by the relative de Rham complex, in the degrees from minus the dimension of the fibre to 0; holonomy is kept, by Bernstein's theorem). So in the spectral sequence of a composite the only term of total degree 0 is H^0 of H^0, and no differential reaches it or leaves it: $H^0(N\circ M)_+=H^0N_+\circ H^0M_+$ on modules. Along a product of maps the direct image is the external product of the direct images (the Künneth formula for $\mathcal{D}$-modules), and in degree 0 the only term is the external product of the H^0. By induction from the marks up,

$$\mathbb{G}_v=H^0(N_v)_+\Big(\boxtimes_c H^0(\lambda_c)_+\mathcal{O}_{T_c}\Big)=H^0\Big(N_v\circ\prod_c\lambda_c\Big)_+\mathcal{O}_{T_v}=H^0(\lambda_v)_+\mathcal{O}_{T_v}.$$

At the root, a direct image restricted to an open set of the target is the direct image from its preimage, so by (i) $H^0(R_o|_{U_o})_+\big((\boxtimes_c\mathbb{G}_c)|_{U_o}\big)$ is the direct image along φ of the functions of the letter complement $\widetilde{X}$ in $(\mathbb{C}^\times)^{\mathcal{E}}$. On the chart $\alpha_{e_0}=1$, $\widetilde{X}=\mathbb{C}^\times\times X_F$ and φ does not depend on the first factor, f having the degree 0; so this direct image is $\mathcal{G}_F\otimes H^1_{\mathrm{dR}}(\mathbb{C}^\times)$, the second factor $\mathbb{C}\,[d\alpha_{e_0}/\alpha_{e_0}]$ in the top degree, where $\mathcal{G}_F$ is the direct image of $\mathcal{O}_{X_F}$ along φ in degree 0: Definition 39.47 is its relative de Rham complex, written on the forms $h\,\omega_0$, and for an integral origin ω_0 is a unit of $\mathbb{C}[X_F]$ times dy.

(iii) For a mark, $\mathbb{G}_e$ is the direct image of the simple module $\mathcal{O}_{\mathbb{C}^\times}$ under a closed embedding, which is simple (Kashiwara's equivalence for closed embeddings), so ε_e generates it. By induction let $\mathcal{M}_c\to\mathbb{G}_c$ carry ε_c to the class of $\alpha^{\mathbf{q}|_{B_c}}\prod_{e\in B_c}d\alpha_e/\alpha_e$. The induced map $H^0(N_v)_+(\boxtimes_c\mathcal{M}_c)\to H^0(N_v)_+(\boxtimes_c\mathbb{G}_c)=\mathbb{G}_v$ carries ε_v to the class of the product of these forms, which is the class of $\alpha^{\mathbf{q}|_{B_v}}\prod_{e\in B_v}d\alpha_e/\alpha_e$ under the identifications of (ii), these being induced by the integration of top forms along the fibres and the top form of a product being the product of the top forms. So it carries $\mathcal{M}_v$, generated by ε_v, onto the submodule generated by that class. At the root the factor of ε_o is a unit of $\mathcal{O}(U_o)$, equal to $\prod_j K_j^{-s_{0j}}(\alpha^{-\mathcal{E}}\Psi_j)^{-t_{0j}}$ by (i), so ε_o goes to the class of

$$\alpha^{\mathbf{q}}\prod_j K_j^{-s_{0j}}\big(\alpha^{-\mathcal{E}}\Psi_j\big)^{-t_{0j}}\prod_e d\alpha_e/\alpha_e=\alpha^{\mathbf{m}_0}\prod_j K_j^{-s_{0j}}\Psi_j^{-t_{0j}}\prod_e d\alpha_e/\alpha_e,$$

which on the chart is $\omega_0 \wedge d\alpha_{e_0}/\alpha_{e_0}$: the element 1 of $\mathcal{G}_F$ times the factor of the scale. So $\mathcal{M}_o$ maps onto $\mathcal{D}_F[1]$.

(iv) A quotient of a module that is a connection near t_0 is a connection there, and characteristic cycles are additive and nonnegative along exact sequences, so the singular values and the vanishing ranks of $\mathcal{D}_F[1]$ are bounded by those of $\mathcal{M}_o$; Theorem 39.49(ii), (iii) turns them into the nonzero roots of the symbol and their multiplicities. All the modules here are holonomic, so of finite length. For an exact sequence $0 \to M' \to M \to M'' \to 0$ the triangle of direct images and the vanishing in positive degrees give the exact sequence $H^0N_+M' \to H^0N_+M \to H^0N_+M'' \to 0$, so every composition factor of H^0N_+M is one of H^0N_+M' or of H^0N_+M'', and by induction on the length one of H^0N_+S for a composition factor S of M. The external product is exact in each factor, and the external product of simple holonomic modules is simple, so the composition factors of $\boxtimes_c M_c$ are the $\boxtimes_c S_c$; restriction to U_o is exact. With $\mathcal{D}_F[g] \subseteq \mathcal{G}_F$ this gives the statements on composition factors, the $\mathbb{G}_e$ being simple by (iii). By Proposition 39.48 the module of the ray is $\mathbb{C}(k) \otimes_{\mathbb{C}[t\partial_t]} \mathcal{G}_F$, the localization at the nonzero polynomials in $t\partial_t$, which form an Ore set of $\mathcal{D}$, since $t\,p(t\partial_t) = p(t\partial_t - 1)\,t$ and $\partial_t\,p(t\partial_t) = p(t\partial_t + 1)\,\partial_t$. The localization is exact and carries a simple module to a simple module or to 0, and the module that $[g]$ generates is the localization of $\mathcal{D}_F[g]$. □

Theorem 39.57 (The closings, the values and the native gauge). *As stated.*

Proof. The origin form is $u\,dy$ with $u = \omega_0/dy$ a unit of $\mathbb{C}[X_F]$, and $\partial_{y_e} \log u = c_e^{(0)}$ (38.2(ii)), so $(k\,c_e^{(1)} + \partial_{y_e})(ug) = u\,(c_e^{(0)} + k\,c_e^{(1)} + \partial_{y_e})g$. Multiplication by u therefore carries $\mathcal{L}$ onto the relation space of the ray from the origin with the same direction, commutes with Sh, and carries the values, the closings ($\mathsf{C}_j(g) = \mathrm{CT}(ug\,f^{-j})$) and the expansions at $\alpha^\star$ of the one ray to those of the other; so we may take the origin to be 0, $\omega_0 = dy$.

By Theorem 38.14(i), $0 < f \le f(\alpha^\star)$ on the positive orthant with equality only at $\alpha \propto \alpha^\star$, and $f \le C'e^{-c'\|y\|}$ on the chart. The family is one molecule: a union S of molecules has $c_j(S) = 0$ for every j (7.10), and then $\kappa_{1,S} + \kappa_{1,\mathcal{E}\setminus S} = \kappa_{1,\mathcal{E}} = 0$ (8.16), against the positive walls. The Hessian of $\log K_j(e^y)$ in y is the covariance of the basis indicator $\mathbf{1}_T$ under the basis law at e^y (7.16), every basis having positive weight at a real point, and that of $\log \Psi_j(e^y)$ the covariance of $\mathbf{1}_{\mathcal{E}\setminus T}$; so a real direction u' in the kernel of the Hessian of $\log f$ at a real point has $\langle u', \mathbf{1}_T\rangle$ constant over the bases of every table, and u' is constant on the one molecule (7.8), $u' \in \mathbb{R}\mathbf{1}$. The Hessian H of $\log f$ at $\alpha^\star$ is negative definite on $\mathbb{R}^{\mathcal{E}}/\mathbb{R}\mathbf{1}$, and $\alpha^\star$ is a nondegenerate native gauge. Write $f^\star = f(\alpha^\star)$, $\hat{A}_\star = (f^\star)^{-k}k^{(n-1)/2}A_\star$, and, for $m = \sum_l r_l(k)[g_l]$, $\langle m\rangle_k = \sum_l r_l(k)\langle g_l\rangle_k$, $V_{\mathsf{C}}(m)(-j) = \sum_l r_l(-j)\,\mathsf{C}_j(g_l)$ for all large j, and $Q(k)$ for a common denominator of the r_l. By Theorem 38.6(i), the orthant near $\alpha^\star$ being a steepest-descent disc and the rest of it contributing $O((f^\star - \delta)^k)$ for some $\delta > 0$, $\langle g\rangle_k$ has the asymptotic expansion $A_\star(g)$, and $\langle m\rangle_k$ the expansion $A_\star(m)$.

(ii)⇒(iii). If $\langle m\rangle_k = 0$ at all large integers, $A_\star(m)$ is the asymptotic expansion of 0 along the integers, so $A_\star(m) = 0$.

(iii)⇒(ii), and the continuation. For $0 < t < f^\star$ the level sets $\Sigma_t = \{f = t\}$ of the real quotient are compact real-analytic hypersurfaces without critical points. By the coarea formula, $\langle g\rangle_k = \int_0^{f^\star} t^k \rho_g(t)\,dt$ for $\mathrm{Re}\,k$ large, with $\rho_g(t) = \int_{\Sigma_t} g\,dy/df$ real-analytic on $(0, f^\star)$, and by the Morse lemma at $\log\alpha^\star$, $\rho_g(t) = (f^\star - t)^{(n-3)/2}h_g(t)$ with h_g real-analytic at $f^\star$. With $t = f^\star e^{-s}$, $\langle g\rangle_k = (f^\star)^{k+1}\mathcal{L}[p_g](k+1)$, $\mathcal{L}$ the Laplace transform and $p_g(s) = \rho_g(f^\star e^{-s})$, real-analytic for $s > 0$ and $s^{(n-3)/2}$ times a function analytic at 0. Write $Q(k)r_l(k) = R_l(k+1)$ with polynomials R_l. On distributions supported in $[0,\infty)$, $\mathcal{L}[Dv](\kappa) = \kappa\,\mathcal{L}[v](\kappa)$ with $D = d/ds$, so $Q(k)\langle m\rangle_k = (f^\star)^{k+1}\mathcal{L}[E](k+1)$ for $\mathrm{Re}\,k$ large, with $E = \sum_l R_l(D)\big(p_{g_l}\mathbf{1}_{s>0}\big)$. On $(0,\infty)$, E is the real-analytic

function $\sum_l R_l(d/ds)\,p_{g_l}$; near 0 it is a convergent sum $\sum_\lambda c_\lambda s^\lambda$ times $\mathbf{1}_{s>0}$, a finite part where needed, with $\lambda \in \frac{n-3}{2}+\mathbb{Z}$ and never a negative integer (for odd n the function part is analytic at 0), plus finitely many derivatives $\delta^{(b)}$ of the Dirac measure at 0. By Watson's lemma

$$\mathcal{L}[E](\kappa) \;\sim\; \sum_\lambda c_\lambda\,\Gamma(\lambda+1)\,\kappa^{-\lambda-1} + \sum_b d_b\,\kappa^b,$$

in distinct powers, with $\Gamma(\lambda+1)\neq 0$, and this is the expansion of $(f^\star)^{-k-1}Q(k)\langle m\rangle_k$, which is $(f^\star)^{-1}Q(k)k^{-(n-1)/2}\hat{A}_\star(m)$. So if $A_\star(m)=0$, every c_λ and every d_b vanishes, E vanishes near 0, hence on $(0,\infty)$ by analyticity, hence $E=0$: $Q(k)\langle m\rangle_k = 0$ for $\operatorname{Re} k$ large, and the continuation of $\langle m\rangle_k$ vanishes identically.

(iii)⇒(i). By what precedes the continuation of $\langle m\rangle_k$ vanishes, and by Proposition 39.34, $V_1V_{\mathsf{C}}(m)(-j) = \lim_{k\to -j}(k+j)^{n-1}\langle m\rangle_k = 0$ for all large j.

(i)⇒(iii), and the expansion of the closings. The constant term of a Laurent polynomial is its mean over every torus $|\alpha_e|=\rho_e$. On the one through $\alpha^\star$, $\alpha=\alpha^\star e^{i\theta}$ with $\theta\in\mathbb{R}^{\mathcal{E}}/(2\pi\mathbb{Z}^{\mathcal{E}}+\mathbb{R}\mathbf{1})$ and $d\theta$ the measure of the chart $\theta_{e_0}=0$,

$$\mathsf{C}_j(g) = (2\pi)^{-(n-1)}\int g(\alpha^\star e^{i\theta})\,f(\alpha^\star e^{i\theta})^{-j}\,d\theta, \qquad j\geq j(g).$$

The letters have nonnegative coefficients, so $|K_j(\alpha^\star e^{i\theta})|\leq K_j(\alpha^\star)$, $|\Psi_j(\alpha^\star e^{i\theta})|\leq \Psi_j(\alpha^\star)$ and $|f^{-1}(\alpha^\star e^{i\theta})|\leq 1/f^\star$, with equality only when $\langle\theta,\mathbf{1}_T\rangle$ is the same modulo 2π for all bases T of every table. For linked marks e,e' some basis T has $e\in T$, $e'\notin T$ and $(T\setminus\{e\})\cup\{e'\}$ a basis (7.7), so equality gives $\theta_e\equiv\theta_{e'}$; the family being one molecule, θ is constant modulo 2π, and $\alpha=\alpha^\star$. So the torus outside a neighbourhood of $\alpha^\star$ contributes $O\big((1-\delta)^j(f^\star)^{-j}\big)$ for some $\delta>0$, $g\,f^{-j(g)}$ being bounded on it. Near $\theta=0$, $\log f(\alpha^\star e^{i\theta})-\log f^\star = -\frac12\theta^{\mathsf{T}}H\theta+O(|\theta|^3)$, whose real part has a nondegenerate minimum at 0, and Laplace's method there is the formal expansion at $\alpha^\star$ under the substitution $y=i\theta$, $k=-j$. The coefficient of k^{-i} in $\hat{A}_\star(g)$ is a sum of Gaussian moments of covariance $(-H)^{-1}$ and of degree $2i+2L$, each times one Taylor coefficient of g and L of $\log f$; the substitution multiplies such a term by $i^{2i+2L}(-1)^L=(-1)^i$ and keeps the covariance, while $(2\pi i)^{-(n-1)}\prod_{e\neq e_0}d\alpha_e/\alpha_e = (2\pi)^{-(n-1)}d\theta$. This gives the expansion of $j^{(n-1)/2}(f^\star)^j\,\mathsf{C}_j(g)$ in the statement, and the same holds for m, with $\hat{A}_\star(m)=\sum_l r_l(k)\hat{A}_\star(g_l)$ read at $k=-j$ as a series in $1/j$. If $V_{\mathsf{C}}(m)=0$, that series is the expansion of 0, so $\hat{A}_\star(m)=0$. □

Corollary 39.59 (When the closings miss nothing). *As stated.*

Proof. By Theorem 39.57, $\operatorname{Ann}(V_{\mathsf{C}})\cap\mathfrak{N}$, $\operatorname{Ann}(\langle\cdot\rangle)\cap\mathfrak{N}$ and $\operatorname{Ann}(A_\star)\cap\mathfrak{N}$ are one submodule (Theorem 39.4(ii)), and it is 0 exactly when $\alpha^\star$ sees every nonzero submodule, being itself a submodule on which $A_\star$ vanishes. A symmetry maps the positive orthant onto itself and keeps f (Proposition 39.11(ii)), so it fixes $\alpha^\star$, the one point there of largest value, and $A_\star\circ\phi^*=A_\star$ (Theorem 39.12(iii)); so $A_\star$, and with it the values and the closings, vanish on $(1-e_G)\mathfrak{M}$.

For the rest, $\mathbf{B}$ regular at ∞ makes the $\mathbb{C}[[1/k]]$-lattice Λ spanned by the masters stable under Sh^{-1}. For a submodule $\mathfrak{N}'$, $\Lambda'=\Lambda\cap(\mathfrak{N}'\otimes\mathbb{C}((1/k)))$ is a lattice of $\mathfrak{N}'\otimes\mathbb{C}((1/k))$, stable as well and saturated in Λ, so in a basis of Λ' the matrix of Sh^{-1} is regular at ∞, with value there the restriction of $\mathbf{B}(\infty)$ to $\Lambda'/k^{-1}\Lambda'\subseteq\Lambda/k^{-1}\Lambda$. The proof of Theorem 39.45 runs for any basis over $\mathbb{C}((1/k))$ in which the matrix is regular at ∞, so it applies to $\mathfrak{N}'$, and each of its pieces maps by zero to the pieces of $\mathfrak{N}$ of other spectra, as in the uniqueness there, so $\mathfrak{N}'\otimes\mathbb{C}((1/k))$ is the direct sum of its intersections with the $\hat{\mathfrak{N}}_a$. $A_\star$ vanishes on the pieces other than $\hat{\mathfrak{N}}_\star$ (Theorem 39.45), and not on $\hat{\mathfrak{N}}_\star$, since it does not vanish on $\mathfrak{N}$; $\hat{\mathfrak{N}}_\star$ being a line, $A_\star$ vanishes on $\mathfrak{N}'$ exactly when

$\hat{\mathfrak{N}}_\star \not\subseteq \mathfrak{N}' \otimes \mathbb{C}((1/k))$. If every nonzero submodule contains $\hat{\mathfrak{N}}_\star$, any two of them meet in a nonzero submodule, completion commuting with intersection, so the intersection of all of them is nonzero and is the only minimal one. Of two nonzero submodules with intersection 0 at most one contains $\hat{\mathfrak{N}}_\star$, and the closings annihilate the other. □

Corollary 39.60 (What the closings determine). *As stated.*

Proof. The kernel of the values is a submodule, so Sh induces on the value module a bijection with $\mathrm{Sh}(r\,m) = \varsigma(r)\,\mathrm{Sh}(m)$, and by Theorem 39.57, V_{C} induces on it a solution that annihilates nothing; the proofs of Theorem 39.4(i), (iii) and (iv) use no more than this. For the recurrences, $\sum_i p_i(k)\langle 1\rangle_{k+i}$ is the value of $m = \sum_i p_i(k)\,\mathrm{Sh}^i[1]$, and $V_{\mathsf{C}}(m)(-j) = \sum_i p_i(-j)\,\mathsf{C}_{j-i}(1)$; by Theorem 39.57 the one vanishes for all large arguments exactly when the other does, so the least orders agree. □

Proposition 39.61 (The closings measure what they miss). *As stated.*

Proof. The closings are a solution (Theorem 39.33), and as in the proof of Theorem 39.4(iii), $(P, Q) \in \mathcal{S}_D$ exactly when every row of $Q\mathbf{B_b} - P$, read in $\mathfrak{N}$, lies in $\mathfrak{A} = \mathrm{Ann}(V_{\mathsf{C}}) \cap \mathfrak{N}$. In the coordinates of the masters $\mathfrak{A}$ is a d-dimensional subspace of $\mathbb{C}(k)^{1\times\mathfrak{m}}$; let $\mathfrak{A}_D$ be its rows of polynomials of degree at most D. Projecting to d coordinates on which $\mathfrak{A}$ projects isomorphically gives $\dim \mathfrak{A}_D \le d(D+1)$, and polynomial rows $a_1, \dots, a_d$ spanning $\mathfrak{A}$, of degrees ν_i, give the independent rows $\sum_i c_i a_i$, $\deg c_i \le D - \nu_i$, so $\dim \mathfrak{A}_D = dD + O(1)$. On $\mathcal{S}_D$ the map $(P, Q) \mapsto Q$ has fibres that are empty or translates of $\mathfrak{A}_D^{\mathfrak{m}}$, each row of P being fixed modulo $\mathfrak{A}$ by Q; its image lies in the polynomials of degree at most D and contains cQ_0 for $\deg c \le D - D_0$. So $\mathfrak{m}\dim \mathfrak{A}_D + D - D_0 + 1 \le \dim \mathcal{S}_D \le \mathfrak{m}\dim \mathfrak{A}_D + D + 1$ for $D \ge D_0$, which is $(\mathfrak{m}d+1)D + O(1)$; for $d = 0$, Theorem 39.4(iv) gives $\dim \mathcal{S}_D = \max(0, D - D_0 + 1)$, whose steps are 0 and 1. □

Proposition 39.62 (A table one mark larger). *As stated.*

Proof. By Corollary 20.19, $\mathcal{B}'$ has no loop or coloop and its letters agree, $\Psi' = K'$. The bases of $\mathcal{B}'$ through g, less g, are the bases of $\mathcal{B}$, and complementation in $\mathcal{E}'$ carries the bases through g onto the bases avoiding g, with the same weights; so $K' = \sum_{T \not\ni g} \theta'_T \alpha^T + \alpha_g \sum_{T \ni g} \theta'_T \alpha^{T\setminus g} = \Psi + \alpha_g K$, and $K(\mathbf{1}) = \Psi(\mathbf{1})$. The deletion $\mathcal{B}' \setminus g$ is the dual of the contraction, and a connected table has a connected deletion or a connected contraction at each mark (Tutte), duality keeping connectedness; so $\mathcal{B}$ is connected, and both centre rays have positive walls (Definition 38.13). Write $x_{a,j}(h) = \alpha_g^a K'^{-j} h$; the monomials and the chances of $\mathcal{B}'$ are of this form, so these span $\mathbb{C}[X_{F'}]$.

(i) For α in the positive orthant, $\int_0^\infty \rho^{\nu-1}(c_0 + c_1\rho)^{-s}\,d\rho = \Gamma_1^2\!\left[\begin{matrix}\nu,\ s-\nu\\ s\end{matrix}\right] c_0^{\nu-s} c_1^{-\nu}$ gives

$$\int_0^\infty \alpha_g^{k+a}(\Psi + \alpha_g K)^{-2k-j}\,\frac{d\alpha_g}{\alpha_g} = \Gamma_1^2\!\left[\begin{matrix}k+a,\ k+j-a\\ 2k+j\end{matrix}\right] \Psi^{a-j-k} K^{-a-k}, \qquad k > \max(-a, a-j),$$

and with $f'^k = \alpha^{k\mathbf{1}}\alpha_g^k K'^{-2k}$, $f^k = \alpha^{k\mathbf{1}}(K\Psi)^{-k}$ and $\Gamma_1^2\!\left[\begin{matrix}k+a,\ k+j-a\\ 2k+j\end{matrix}\right] = r_{a,j}(k)\Gamma_1^2\!\left[\begin{matrix}k,\ k\\ 2k\end{matrix}\right]$ this is the identity for $g' = x_{a,j}(h)$. The integral is linear in g', so on a combination of the $x_{a,j}(h)$ the defining formula depends only on the function they sum to, both sides being rational in k and equal for all large k; so π_* is well defined and $\mathbb{C}(k)$-linear on $\mathbb{C}[X_{F'}] \otimes \mathbb{C}(k)$, and the identity holds for every insertion. On the chart $y_{e_0} = 0$ the form of F' is $dy\,d\alpha_g/\alpha_g$, and its positive orthant is that of F times $(0, \infty)$; Fubini gives the values. The constant term in α_g of $x_{a,j}(h) f'^{-J} = \alpha_g^{a-J}\alpha^{-J\mathbf{1}} h\,(\Psi + \alpha_g K)^{2J-j}$ is $\binom{2J-j}{J-a}\Psi^{J-j+a}K^{J-a}\alpha^{-J\mathbf{1}}h$, and for $J \ge |a| + j$,

$\Gamma(x-J)/\Gamma(-J) = (-1)^x J!/(J-x)!$ gives $r_{a,j}(-J) = \binom{2J-j}{J-a}\big/\binom{2J}{J}$; so that constant term is $\binom{2J}{J}\,\pi_*\big(x_{a,j}(h)\big)\big|_{k=-J} f^{-J}$, and the constant term in the remaining scales gives the closings.

On $X_{F'}$, $c_g'^{(1)} = \partial_{y_g} \log f' = 1 - 2\alpha_g K/K'$, which is -1 where $\Psi = 0$ and 1 where $K = 0$; where $K\Psi \neq 0$ it vanishes exactly at $\alpha_g = \Psi/K$, where $K' = 2\Psi$, $f' = f/4$ and $\partial^2_{y_g} \log f' = -2\,\frac{\alpha_g K}{K'}\,\frac{\Psi}{K'} = -\frac{1}{2}$. So $\log f(\alpha) = \log 4 + \log f'(\alpha, \Psi/K)$ on X_F, the defects of F' at $(\alpha, \Psi/K)$ in the marks of $\mathcal{E}$ are those of F at α, the native gauges of F' are the points $\alpha_{c'}$, and the Hessian of $\log f$ at α_c is the Schur complement of the entry $-\frac{1}{2}$ in the Hessian of $\log f'$ at $\alpha_{c'}$, whose determinant is $-\frac{1}{2}$ times that of the complement. Over a steepest-descent disc D_c, with Morse coordinates v, put $\alpha_g = e^s\,\Psi/K$; then $d\alpha_g/\alpha_g = ds$ on the fibre and

$$\log f' = \log f(\alpha_c) - \log 4 - \tfrac{1}{2}\textstyle\sum_i v_i^2 - 2\log\cosh\frac{s}{2},$$

so with the real-analytic coordinate w of the sign of s and $\frac{1}{2}w^2 = 2\log\cosh\frac{s}{2}$, the image of $D_c \times \{|s| \le \varepsilon\}$ is a steepest-descent disc at $\alpha_{c'}$. The integral over all s is the Beta corner, the part with $|s| > \varepsilon$ is exponentially smaller, and the expansion at $\alpha_{c'}$ is that of the Beta corner times $A_c(\pi_* g')$.

(ii) Let $\rho'_e(g') = (k\,c_e'^{(1)} + \partial_{y_e})g'$, so that $f'^k \rho'_e(g') = \partial_{y_e}(f'^k g')$, and likewise ρ_e for F. Differentiating the identity of (i) under the integral, $\pi_*\rho'_e = \rho_e \pi_*$ for $e \in \mathcal{E}$; and $\pi_*\rho'_g = 0$, the integral of $\partial_{y_g}(f'^k g')$ over $(0,\infty)$ vanishing for large k. Both are identities between elements of $\mathbb{C}[X_F] \otimes \mathbb{C}(k)$ that hold for all large k, so they hold. Next,

$$\rho'_g\big(x_{a,j}(h)\big) = (k+a)\,x_{a,j}(h) - (2k+j)\,x_{a+1,j+1}(Kh), \qquad x_{a,j}(h) = x_{a,j+1}(\Psi h) + x_{a+1,j+1}(Kh),$$

so modulo the span $\mathcal{L}'_g$ of the $\rho'_g(g')$

$$x_{a,j}(h) \equiv \frac{2k+j}{k+a}\,x_{a+1,j+1}(Kh) \equiv \frac{2k+j}{k+j-a}\,x_{a,j+1}(\Psi h).$$

A finite sum $z = \sum_i c_i x_{a_i,j_i}(h_i)$ is therefore congruent modulo $\mathcal{L}'_g$ to one term $x_{A,A+B}(H)$, for any $A \ge \max_i a_i$ and $B \ge \max_i(j_i - a_i)$, with H a Laurent polynomial, and $\pi_* z = r_{A,A+B} K^{-A} \Psi^{-B} H$; if $\pi_* z = 0$ then $H = 0$ and $z \in \mathcal{L}'_g$. And π_* is onto: $\pi_* x_{a,a+b}(\alpha^u) = r_{a,a+b}\,\alpha^u K^{-a}\Psi^{-b}$ for $a, b \ge 0$, with $r_{a,a+b} \neq 0$, and these span $\mathbb{C}[X_F]$. So π_* is a bijection of $(\mathbb{C}[X_{F'}] \otimes \mathbb{C}(k))/\mathcal{L}'_g$ onto $\mathbb{C}[X_F] \otimes \mathbb{C}(k)$ that carries $\mathcal{L}' = \mathcal{L}'_g + \sum_{e\in\mathcal{E}} \rho'_e(\cdot)$ onto $\sum_{e\in\mathcal{E}} \rho_e(\cdot) = \mathcal{L}$, and it induces a bijection $\mathfrak{M}' \to \mathfrak{M}$. Finally $\Gamma{}^{2}_{1}\!\begin{bmatrix} k+1,\ k+1 \\ 2k+2 \end{bmatrix} = \frac{k}{2(2k+1)}\Gamma{}^{2}_{1}\!\begin{bmatrix} k,\ k \\ 2k \end{bmatrix}$, so $\pi_*(f'g') = \frac{k}{2(2k+1)}\, f \wr (\pi_* g')$.

(iii) By (ii) T_β is a $\mathbb{C}(k)$-linear bijection of $\mathfrak{M}$. ϕ_β is a symmetry of F' (Proposition 39.11(ii)), so ϕ_β^* commutes with Sh' (Theorem 39.12(i)); with $c = \frac{k}{2(2k+1)}$, $\mathrm{Sh} = c^{-1}\pi_* \mathrm{Sh}'\, \pi_*^{-1}$, and then $T_\beta \mathrm{Sh} = c^{-1}\pi_*\phi_\beta^* \mathrm{Sh}'\, \pi_*^{-1} = c^{-1}\pi_* \mathrm{Sh}'\, \phi_\beta^* \pi_*^{-1} = \mathrm{Sh}\, T_\beta$. If $\beta(g) = g$, comparing the coefficients of α_g^0 and α_g^1 in $K' \circ \phi_\beta = K'$ gives $K \circ \phi_\beta = K$ and $\Psi \circ \phi_\beta = \Psi$, so ϕ_β restricted to $\mathcal{E}$ is a symmetry of F and $\pi_* \phi_\beta^* = \phi_\beta^* \pi_*$ on the $x_{a,j}(h)$. For the transposition of e and g, $\phi_\beta^* \alpha^u = x_{u_e,0}(\alpha^{u - u_e \mathbf{1}_e})$, and π_* of it is the stated class, with $r_{u_e,0}(k) = \Gamma(k+u_e)\Gamma(k-u_e)/\Gamma(k)^2$. For the Cremona, $K' \circ \mathrm{cr} = \alpha^{-\mathbf{1}} \alpha_g^{-1} K'$, $K \circ \mathrm{cr} = \alpha^{-\mathbf{1}}\Psi$ and $\Psi \circ \mathrm{cr} = \alpha^{-\mathbf{1}} K$ (Proposition 39.11(i)), so $\mathrm{cr}^*\, x_{a,j}(h) = x_{j-a,j}\big(\alpha^{j\mathbf{1}}\, h \circ \mathrm{cr}\big)$, and both $\pi_* \mathrm{cr}^*\, x_{a,j}(h)$ and $\mathrm{cr}^*\, \pi_* x_{a,j}(h)$ are $r_{a,j}\, \Psi^{-a} K^{a-j} \alpha^{j\mathbf{1}}\, h \circ \mathrm{cr}$, as $r_{j-a,j} = r_{a,j}$. The group generated is the image of the finite group generated by the ϕ_β and the Cremona of F'.

(iv) The values and the closings of F' are kept by every ϕ_β and by its Cremona (Proposition 39.11(ii); the torus and the constant term are kept by every permutation of the scales and by their inversion). By (i) the values and the closings of F are those of F' composed with π_*^{-1},

divided by $\Gamma_{\substack{2\\1}}\begin{bmatrix}k,\ k\\ 2k\end{bmatrix}$ and by $\binom{2j}{j}$, which do not depend on the insertion; so they are invariant under G'. The native gauge of the direction of F' on the positive orthant is unique up to scale (Theorem 38.14(i)), so it is fixed by every ϕ_β and by the Cremona, and it is $\mathbf{1}$; on the orthant $f' \le f/4$, with equality exactly at $\alpha_g = \Psi/K$, so it lies over $\alpha^\star$, and $\alpha^\star = \mathbf{1}$. Then $A'_\star \circ \phi^*_\beta = A'_\star$ (Theorem 39.12(iii)), and $A_\star \circ T_\beta = A_\star$ by (i). A solution V invariant under G' has $V = V \circ e_{G'}$ and vanishes on $(1 - e_{G'})\mathfrak{M}$. If $G \subseteq G'$, then $e_{G'}e_G = e_{G'}$, so $e_{G'}$ maps $\mathfrak{M}^G$ onto $\mathfrak{M}^{G'} \subseteq \mathfrak{M}^G$, and $\mathfrak{M}^G = e_{G'}\mathfrak{M}^G \oplus (1 - e_{G'})\mathfrak{M}^G$, both submodules since $e_{G'}$ commutes with Sh. Last, π_* intertwines the action on $\mathfrak{M}'$ with G', so it carries the invariant module of F' onto $\mathfrak{M}^{G'}$. □

Corollary 39.63 (The cousins of a fused table). *As stated.*

Proof. $\mathcal{B}^\sharp$ is connected by Corollary 30.7(ii), and identically self-dual. For a mark x of $\mathcal{E} \sqcup G$ the cousin at x is the contraction $\mathcal{B}^\sharp/x$, and Proposition 39.62 applies with $(\mathcal{B}', \theta') = (\mathcal{B}^\sharp, \theta^\sharp)$, its $n + c - 1 \ge 2$ marks other than x, and the mark x in the place of g. □

Proposition 39.64 (What a table one mark larger hides from the closings). *As stated.*

Proof. (i) For a nondegenerate native gauge $\alpha_{c'}$ of F' and $\gamma \in \Gamma'$, $A'_{c'} \circ \gamma^*$ is a nonzero constant multiple of the expansion over the steepest-descent disc $\gamma(D_{c'})$ at $\gamma(\alpha_{c'})$, and $A'_{c'} \circ \psi^* = A'_{c'}$ when $\psi \in \Gamma'$ fixes $\alpha_{c'}$ (proof of Theorem 39.12(iii)). Two γ that carry $\alpha_{c'_0}$ to one point differ by an element of its stabilizer, and $(\gamma\psi)^* = \psi^*\gamma^*$, so the transported $A'_{c'}$ is well defined, and $A'_{c'} \circ \chi^* = A'_{\chi(c')}$ for every $\chi \in \Gamma'$. By Proposition 39.62(i), A_c is a nonzero constant multiple of the expansion of F at α_c: a solution of the type $\big(f(\alpha_c), -\frac{n-1}{2} + \mathbb{Z}\big)$, $n = |\mathcal{E}|$, whose leading coefficient on an insertion h is $C_c\, h(\alpha_c)$ with $C_c \ne 0$ (Theorem 38.6(i)). The native gauges below one orbit O'_a have one native value, $4f'$ at the points of O'_a, which Γ' keeps, and so one type.

Every element of G' is $T_\gamma = \pi_*\gamma^*\pi_*^{-1}$ for some $\gamma \in \Gamma'$ (Proposition 39.62(iii)), and $A_c \circ T_\gamma = \Gamma_{\substack{2\\1}}\begin{bmatrix}k,\ k\\ 2k\end{bmatrix}^{-1} A'_{\gamma(c')} \circ \pi_*^{-1} = A_{\gamma\cdot c}$, with $\gamma\cdot c$ the native gauge below $\gamma(\alpha_{c'})$. For $\phi \in G$, $\phi^* = T_\gamma$ with γ the map of the same kind on the torus of F', and the lift commutes with ϕ: ϕ_β, $\beta(g) = g$, keeps K and Ψ, and $\Psi(\alpha^{-1})/K(\alpha^{-1}) = K(\alpha)/\Psi(\alpha)$ (Proposition 7.2). So $\gamma\cdot c = \phi(\alpha_c)$ and $A_c \circ \phi^* = A_{\phi(\alpha_c)}$. Let $O_{a,1}, \dots, O_{a,s_a}$ be the orbits of G below O'_a and $V_{a,i} = \sum_{c \in O_{a,i}} A_c$; each $\phi \in G$ permutes $O_{a,i}$, so $V_{a,i}$ is invariant under G. For $x \in \mathfrak{M}^{G'}$ and native gauges α_c, $\alpha_{\tilde c}$ below O'_a, with $\gamma(\alpha_{c'}) = \alpha_{\tilde c'}$, $A_{\tilde c}(x) = A_c(T_\gamma x) = A_c(x)$; so $V_{a,i}(x) = |O_{a,i}|\, A_c(x)$ for any α_c below O'_a, and

$$W_{a,i} = |O_{a,i}|^{-1} V_{a,i} - |O_{a,1}|^{-1} V_{a,1}, \qquad 2 \le i \le s_a,$$

vanish on $\mathfrak{M}^{G'}$.

The $V_{a,i}$ of one type are linearly independent over $\mathbb{C}$ on $\mathfrak{M}^G$. Let $\sum \gamma_{a,i} V_{a,i}$ vanish on $\mathfrak{M}^G$, the sum over those of one type, and fix (a, i) and $\alpha_c \in O_{a,i}$. As in the proof of Theorem 39.12(iii), take an insertion h with $h(\alpha_c) = 1$ that vanishes to the order $N \ge 2$ at the other native gauges below $O'_1, \dots, O'_q$, which are finitely many; the expansion at such a point is smaller than the leading power of the type by the factor $k^{-\lceil N/2 \rceil}$. The class of $e_G h$ lies in $\mathfrak{M}^G$, and every $V_{a',i'}$, being invariant, takes the same value at $e_G h$ and at h; so the leading coefficient of the relation at $e_G h$ is $\gamma_{a,i} C_c$, and $\gamma_{a,i} = 0$. Each $W_{a,i}$ involves its own $V_{a,i}$, so the $W_{a,i}$ of one type are linearly independent over $\mathbb{C}$ on $\mathfrak{M}^G$. They vanish on $\mathfrak{M}^{G'}$, and $\mathfrak{M}^G = \mathfrak{M}^{G'} \oplus (1 - e_{G'})\mathfrak{M}^G$ (Proposition 39.62(iv)), so a combination of them that vanishes on $(1 - e_{G'})\mathfrak{M}^G$ vanishes on $\mathfrak{M}^G$: they are linearly independent over $\mathbb{C}$ on $(1 - e_{G'})\mathfrak{M}^G$, type by type. Lemma 39.3 gives the bound; $(1 - e_{G'})\mathfrak{M}^G$ is a submodule,

$e_{G'}$ commuting with Sh, and the closings, the values and $A_\star$ vanish on it by Proposition 39.62(iv). The solution of the last statement is $-W_{a,2}$ for an indexing with $O_{a,1} = O_1$ and $O_{a,2} = O_2$.

(ii) A nonempty proper $S \subseteq [2r+2]$ meets the bases of $\binom{[2r+2]}{r+1}$ in every number of marks from $\max(0, |S| - r - 1)$ to $\min(|S|, r+1)$, so $c(S) > 0$ and the table is connected (Definition 8.1); the complement of a set of $r+1$ of its marks has $r+1$ marks, so it is identically self-dual; and its contraction at g (Definition 7.3) has the bases $T \setminus \{g\}$, $T \ni g$, the sets of r marks of $[2r+1]$, with $K = e_r$ and $\Psi = e_{r+1}$, the elementary symmetric polynomials of $\alpha_1, \dots, \alpha_{2r+1}$. So Proposition 39.62 applies, $|\mathcal{E}| = 2r+1 \geq 5$. Every bijection of $[2r+2]$ is an automorphism, so G consists of the ϕ_β, β a bijection of $[2r+1]$, and their composites with the Cremona. These are the symmetries of the four kinds of the centre ray (Proposition 39.11(ii), the masses being $\mathbf{1}$ and the exponents $s = t = 1$): a bijection that exchanged the list would carry its bases, of r marks, onto complements of bases, of $r+1$ marks, so there are no exchanges and no reversed exchanges.

At a sign η with i coordinates -1 among $l+i$, $e_m(\eta)$ is the coefficient of z^m in $(1-z)^i(1+z)^l$. With $\binom{2r}{r-1} = \binom{2r}{r+1} = rC_r$, $\binom{2r-1}{r-1} = \binom{2r-1}{r} = \frac{r+1}{2}C_r$ and $\binom{2r-1}{r-2} = \frac{r-1}{2}C_r$,

$$[z^r](1-z)(1+z)^{2r} = C_r, \qquad [z^r](1-z)^2(1+z)^{2r-1} = -C_r,$$

so $K(\eta) = e_r(\eta) = \pm C_r \neq 0$ at the signs of F with one and with two scales -1, which are native gauges of the native value $K(\eta)^{-2} = C_r^{-2}$ (Theorem 38.17(ii)). The bijections of $[2r+1]$ act transitively on the marks and on the pairs of marks, the Cremona fixes every sign, and a sign with one coordinate -1 is not a multiple of one with two, $2r+1 \geq 5$: the signs form two orbits of G. At a sign $\eta^{-1} = \eta$, so $\Psi(\eta) = \eta^{\mathcal{E}} K(\eta)$ (Proposition 7.2), and the native gauge above η is $(\eta, \eta^{\mathcal{E}})$, with $\eta^{\mathcal{E}} = -1$ for one scale -1 and $\eta^{\mathcal{E}} = 1$ for two: the native gauges above the two kinds are the $\binom{2r+2}{2}$ signs of F' with two scales -1, each once, and the bijections of $[2r+2]$ act transitively on them.

At such a sign η', with $D = \{a_1, a_2\}$ and C as in the statement, $a \in D$ and $c, c' \in C$, the Hessian of $-\log f'$ is 2κ, κ the covariances of the indicators X_e of the marks under the signed measure $\mathbb{P}(T) = \eta'^T / K'(\eta')$ on the sets T of $r+1$ marks (Theorem 38.17(ii), $K' = \Psi'$); as a matrix on $\mathbb{C}^{\mathcal{E}'}$ it has zero row sums, $\sum_e X_e = r+1$. From $[z^{r+1}](1-z)^2(1+z)^{2r} = 2rC_r - 2(r+1)C_r$, $[z^{r-1}](1-z)(1+z)^{2r-1} = C_r$ and, with $\binom{2r-2}{r-1} = \frac{r(r+1)}{2(2r-1)}C_r$,

$$[z^{r-1}](1-z)^2(1+z)^{2r-2} = \binom{2r-2}{r-1}\Big(1 - \frac{2(r-1)}{r} + \frac{(r-1)(r-2)}{r(r+1)}\Big) = -\frac{r-2}{2r-1}\,C_r,$$

$$K'(\eta') = -2C_r, \qquad \mathbb{P}(e \in T) = \tfrac{1}{2}, \qquad \mathbb{P}(a_1, a_2 \in T) = \frac{rC_r}{-2C_r} = -\frac{r}{2},$$
$$\mathbb{P}(a, c \in T) = \frac{1}{2}, \qquad \mathbb{P}(c, c' \in T) = \frac{r-2}{2(2r-1)},$$

the first for every mark, as $\eta'_e e_r(\eta'_{\hat{e}}) = -C_r$ for $e \in D$ and for $e \in C$. So $\kappa_{ee} = \frac{1}{4}$, $\kappa_{a_1a_2} = -\frac{2r+1}{4}$, $\kappa_{ac} = \frac{1}{4}$ and $\kappa_{cc'} = -\frac{3}{4(2r-1)}$, and

$$\kappa(\mathbf{1}_{a_1} - \mathbf{1}_{a_2}) = \tfrac{r+1}{2}(\mathbf{1}_{a_1} - \mathbf{1}_{a_2}), \qquad \kappa(\mathbf{1}_c - \mathbf{1}_{c'}) = \tfrac{r+1}{2(2r-1)}(\mathbf{1}_c - \mathbf{1}_{c'}),$$
$$\kappa(r\mathbf{1}_D - \mathbf{1}_C) = -\tfrac{r+1}{2}(r\mathbf{1}_D - \mathbf{1}_C),$$

the last from its coordinates $r(\frac{1}{4} - \frac{2r+1}{4}) - \frac{2r}{4} = -\frac{r(r+1)}{2}$ at a and $\frac{2r}{4} - \frac{1}{4} + \frac{3}{4} = \frac{r+1}{2}$ at c, where $r\mathbf{1}_D - \mathbf{1}_C$ has the coordinates r and -1. With $c_1 \in C$, the vectors $\mathbf{1}_{a_1} - \mathbf{1}_{a_2}$, $r\mathbf{1}_D - \mathbf{1}_C$ and

$\mathbf{1}_{c_1} - \mathbf{1}_c$, $c \in C \setminus \{c_1\}$, are $2r+1$ independent vectors orthogonal to $\mathbf{1}$, which gives the eigenvalues of $-H' = 2\kappa$ modulo $\mathbf{1}$; they do not vanish, so η' is nondegenerate, and so is the sign below it (Proposition 39.62(i)). A symmetric matrix A of size N' with $A\mathbf{1} = 0$ and rank $N'-1$ has an adjugate of rank one killed by A, so equal to $\lambda\,\mathbf{1}\mathbf{1}^{\mathsf{T}}/N'$ with λ the sum of its principal minors of size $N'-1$, the product of the eigenvalues of A modulo $\mathbf{1}$; so every such minor is λ/N', and on a chart

$$\det(-H') = \frac{(r+1)\cdot(-(r+1))\cdot\left(\frac{r+1}{2r-1}\right)^{2r-1}}{2r+2} = -\frac{(r+1)^{2r}}{2(2r-1)^{2r-1}}.$$

The Hessian of $\log f$ at η is the Schur complement of the entry $-\frac{1}{2}$ in that of $\log f'$ at η' (proof of Proposition 39.62(i)), so on charts with $e_0 \in \mathcal{E}$, $\det H = -2\det H'$ and $\det(-H) = 2\det(-H')$, which is the stated value. Part (i) with the one orbit of the signs of F' with two scales -1, below which lie two orbits of G, gives $(1-e_{G'})\mathfrak{M}^G \neq 0$, and the closings vanish on it. □

Proposition 39.65 (The holonomy of a wheel). *As stated.*

Proof. Put $S(a) = \mathbf{U}(a)$ and $R(b) = \begin{bmatrix} b & 0 \\ 1 & b \end{bmatrix} = b\,\mathbf{L}(b^{-1})$, and $M(\alpha) = \prod_i S(\alpha_{s_i})R(\alpha_{r_i}) = \prod_i \alpha_{r_i} \cdot \mathbf{h}(\alpha)$. Index rows and columns by the states $0, 1$ and read the factors from left to right as steps around the rim, $S(\alpha_{s_i})$ at the vertex i and $R(\alpha_{r_i})$ at the rim r_i: S allows $0 \to 0$, $0 \to 1$ with the weight α_{s_i}, and $1 \to 1$; R allows $0 \to 0$ and $1 \to 1$ with the weight α_{r_i}, and $1 \to 0$ with the weight 1. Then $\operatorname{tr} M$ is the sum over the closed walks of states of the products of the weights. A spanning tree of the wheel omits at least one rim; the rims it omits cut the rim cycle into arcs of consecutive vertices, joined by the rims it contains, and it contains exactly one spoke at a vertex of each arc, at least one for connection and at most one, two closing a cycle through the hub; every such choice is a spanning tree. To a tree corresponds the closed walk in state 0 at the start of each arc and in state 1 from the vertex of its spoke on, leaving 1 for 0 exactly at the omitted rims; its weight is α^T. The closed walks that never go from 1 to 0 stay in one state all around, taking every rim and no spoke: two walks of weight $\prod_i \alpha_{r_i}$. So $\operatorname{tr} M = K + 2\prod_i \alpha_{r_i}$, which is the formula for K. $\det S = 1$ and $\det R(b) = b^2$, so $\det \mathbf{h} = 1$. By 7.2, $\Psi(\alpha) = \alpha^{\mathcal{E}} K(\alpha^{-1}) = \prod_i \alpha_{s_i}\alpha_{r_i} \cdot \prod_i \alpha_{r_i}^{-1}\big(\operatorname{tr}\mathbf{h}(\alpha^{-1}) - 2\big)$.

The transpose of a product is the product of the transposes in the reverse order, $\mathbf{U}(a)^{\mathsf{T}} = \mathbf{L}(a)$ and $\mathbf{L}(b)^{\mathsf{T}} = \mathbf{U}(b)$, so

$$\operatorname{tr}\mathbf{h}(\alpha^{-1}) = \operatorname{tr}\Big(\prod_{i=1}^{p} \mathbf{U}(\alpha_{s_i}^{-1})\mathbf{L}(\alpha_{r_i})\Big)^{\mathsf{T}} = \operatorname{tr}\big(\mathbf{U}(\alpha_{r_p})\mathbf{L}(\alpha_{s_p}^{-1})\cdots\mathbf{U}(\alpha_{r_1})\mathbf{L}(\alpha_{s_1}^{-1})\big) = \operatorname{tr}\mathbf{h}(\alpha\circ x),$$

the factor i of the last product being $\mathbf{U}(\alpha_{r_{p+1-i}})\mathbf{L}(\alpha_{s_{p+1-i}}^{-1}) = \mathbf{U}\big((\alpha\circ x)_{s_i}\big)\mathbf{L}\big((\alpha\circ x)_{r_i}^{-1}\big)$. Then $K(\alpha\circ x) = \prod_i \alpha_{x(r_i)}\big(\operatorname{tr}\mathbf{h}(\alpha\circ x) - 2\big) = \prod_i \alpha_{s_i}\big(\operatorname{tr}\mathbf{h}(\alpha^{-1}) - 2\big) = \Psi(\alpha)$. Comparing the monomials, all with coefficient 1, the sets $x(T)$ of the bases T are the complements of the bases, so $T \mapsto \mathcal{E}\setminus x(T)$ maps the bases onto the bases: x exchanges the list. At $\alpha = \mathbf{1}$, $\mathbf{U}(1)\mathbf{L}(1) = \begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix}$, of trace 3 and determinant 1, with the eigenvalues $\lambda_\pm$, the squares of the golden ratio and of its inverse, and $\mathbf{h}(\mathbf{1})$ is its p-th power, of trace $\lambda_+^p + \lambda_-^p$, the Lucas number of index $2p$, the Lucas numbers being the sums of the powers of the golden ratio and of minus its inverse. □

Proposition 39.66 (The centre ray of a wheel). *As stated.*

Proof. By 38.13, $f = \alpha^{\sigma\mathcal{E}}(K\Psi)^{-\sigma}$, and by Proposition 39.65, $K\Psi = \alpha^{\mathcal{E}}\,\mathfrak{d}\,\mathfrak{d}^*$; so $f = (\mathfrak{d}\,\mathfrak{d}^*)^{-\sigma}$, and $X_F = \{K\Psi \neq 0\} = \{\mathfrak{d}\,\mathfrak{d}^* \neq 0\}$ on the torus. (i) The native gauges are the critical points of

$\log f = -\sigma(\log\mathfrak{d}+\log\mathfrak{d}^*)$ on X_F (38.2(ii), 38.4), where $\mathfrak{d}^*d\mathfrak{d}+\mathfrak{d}\,d\mathfrak{d}^* = 0$, and then $d\mathfrak{d}^* = -(\mathfrak{d}^*/\mathfrak{d})\,d\mathfrak{d}$. (ii) $\eta^{-1} = \eta$, and $\mathfrak{d}(\mathbf{1}) = K(\mathbf{1})$. (iii) Since $\det\mathbf{h} \equiv 1$, $\operatorname{tr}(\mathbf{h}^{-1}d\mathbf{h}) = d\log\det\mathbf{h} = 0$; where $\mathbf{h} = -I$ this is $-\operatorname{tr} d\mathbf{h} = -d\mathfrak{d} = 0$, and the same holds for $\mathfrak{d}^*$ where $\mathbf{h}(\alpha^{-1}) = -I$. On the torsion stratum $\mathfrak{d} = \mathfrak{d}^* = -4$, so it lies in X_F, $d\log f = 0$ there and $f = 16^{-\sigma}$. Each of $\mathbf{h}(\alpha) = -I$ and $\mathbf{h}(\alpha^{-1}) = -I$ is three equations, $\mathbf{h}_{12} = \mathbf{h}_{21} = 0$ and $\mathbf{h}_{11} = -1$, the fourth following from $\det\mathbf{h} = 1$. They do not change under scaling, $\mathbf{h}(c\alpha)$ being $\mathbf{h}(\alpha)$ conjugated by $\operatorname{diag}(c^{1/2}, c^{-1/2})$; on the chart $\alpha_{e_0} = 1$, a torus of dimension $2p-1$, every component of the zero set of six functions has dimension at least $2p-7$. □

Proposition 39.67 (The classes of a wheel). *As stated.*

Proof. The number of spanning trees that contain s_1 is the derivative of K in α_{s_1} at $\mathbf{1}$. With S, R and M as in the proof of Proposition 39.65, $K = \operatorname{tr} M - 2\prod_i \alpha_{r_i}$, and the derivative of S is $\begin{bmatrix}0&1\\0&0\end{bmatrix}$, so that number is the entry $(2,1)$ of $R(1)M_1^{p-1}$, $M_1 = S(1)R(1) = \begin{bmatrix}2&1\\1&1\end{bmatrix}$. With the Fibonacci numbers Fib_m, $M_1 = \begin{bmatrix}1&1\\1&0\end{bmatrix}^2$ and $\begin{bmatrix}1&1\\1&0\end{bmatrix}^m = \begin{bmatrix}\mathrm{Fib}_{m+1}&\mathrm{Fib}_m\\\mathrm{Fib}_m&\mathrm{Fib}_{m-1}\end{bmatrix}$; the second row of $R(1)$ is $(1,1)$, so the entry is $\mathrm{Fib}_{2p-1}+\mathrm{Fib}_{2p-2} = \mathrm{Fib}_{2p} = (\lambda_+^p - \lambda_-^p)/\sqrt{5}$. Dividing by $K(\mathbf{1})$ gives R_{s}. With the Lucas numbers $\mathrm{Luc}_m = \mathrm{Fib}_{m-1}+\mathrm{Fib}_{m+1}$, $\mathrm{Luc}_m - 2\mathrm{Fib}_m = \mathrm{Fib}_{m-3}$, so $2R_{\mathrm{s}} = 1$ reads $\mathrm{Fib}_{2p-3} = 2$, that is $2p-3 = 3$ and $p = 3$. The rotation $i \mapsto i+1$ carries the list, so all spokes have one occupation and all rims one, and Theorem 39.13(i) with x gives $R_{\mathrm{r}} = 1 - R_{\mathrm{s}}$; 9.3 gives the masses. By 11.16 the classes at the centre are the orbits of the bijections that carry or exchange the list, and the rotations with x make one class. At a lean they are the orbits of the bijections that carry the list. For $p \geq 4$ the circuits of three marks are the triangles $\{s_i, s_{i+1}, r_i\}$, so a spoke lies in two of them and a rim in one, and a bijection that carries the list, carrying circuits to circuits, maps spokes to spokes: the classes at a lean are the spokes and the rims, the rotations acting transitively on each. By Theorem 39.13(i), $\bar\phi_x$ keeps the integrand at every lean, and x maps the spokes onto the rims. For $p = 3$ the permutations of the four vertices of K_4 carry the list and act transitively on its six edges. □

50.39 Chapter 40: the stride's law and the gauge end

In this section the chart is $\alpha_{e_0} = 1$ with the coordinates $y = \log\alpha \in \mathbb{R}^{\mathcal{E}\setminus e_0}$, $f^\star = f(\alpha^\star)$, and a differential operator A with polynomial coefficients on $(0,\infty)$ has the formal adjoint $A^\dagger$, with $\langle AT, \phi\rangle = \langle T, A^\dagger\phi\rangle$ for distributions T and test functions ϕ; for $\theta = t\frac{d}{dt}$, $\theta^\dagger = -1-\theta$, so that $p(-1-i-\theta)^\dagger = p(\theta - i)$ and

$$\mathfrak{D}_{\mathbf{p}}^\dagger = \sum_i p_i(\theta - i)\,t^i, \qquad \mathfrak{D}_{\mathbf{p}}^\dagger\,t^k = \sum_i p_i(k)\,t^{k+i}.$$

Five lemmas carry the proofs: a moment lemma, which turns recurrences of moments into equations for measures; the volumes of the sublevel sets of a Morse function; the uniqueness of expansions in powers and logarithms; the formal solutions of a recurrence at a simple root of its symbol; and the point masses that a cut germ produces.

Lemma S21. *Let $\nu_1, \dots, \nu_r$ be complex measures on $(0, R]$ with $\int t^{K_0}\,d|\nu_l| < \infty$ for a real K_0, let $A_1, \dots, A_r$ be differential operators $A_l = \sum_i t^{a_{l,i}} q_{l,i}(\theta)$ with $a_{l,i} \in \mathbb{N}$ and polynomials $q_{l,i}$, and let $E = \sum_l A_l\nu_l$, a distribution on $(0,\infty)$. For $\operatorname{Re} k \geq K_0$ the numbers $M_E(k) = \sum_l \int A_l^\dagger(t^k)\,d\nu_l = \sum_{l,i} q_{l,i}(-1-k-a_{l,i}) \int t^{k+a_{l,i}}\,d\nu_l$ are defined, holomorphic for $\operatorname{Re} k > K_0$.*

(i) If $M_E(k) = 0$ for all large integers k, then $E = 0$.

(ii) If $E = 0$, then $M_E(k) = 0$ for every k with $\operatorname{Re} k \ge K_0$.

Proof. $A_l^\dagger = \sum_i q_{l,i}(-1-\theta)\, t^{a_{l,i}}$, and $\theta\, t^m = m\, t^m$ gives the formula for M_E; the integrals converge absolutely for $\operatorname{Re} k \ge K_0$, t being at most R, and are holomorphic in k for $\operatorname{Re} k > K_0$ by dominated convergence on compact sets.

(i) For $\psi \in C^\infty(\mathbb{R})$ and an integer $K \ge K_0$ put $\Lambda_K(\psi) = \sum_l \int A_l^\dagger(t^K\psi)\, d\nu_l$. Since $\theta(t^m\psi) = t^m(m+\theta)\psi$ and $\theta^c = \sum_{b\le c} S(c,b)\, t^b\partial^b$ with integers $S(c,b)$, $A_l^\dagger(t^K\psi)$ is a finite combination of the functions $t^{K+a+b}\psi^{(b)}$, b at most the largest order d of the A_l, with coefficients that depend on K; so $|\Lambda_K(\psi)| \le C_K \max_{b\le d}\sup_{[0,R]}|\psi^{(b)}|$. For $\psi = t^m$, $\Lambda_K(t^m) = M_E(K+m)$, which vanishes when K is large. Polynomials are dense in $C^d([0,R])$ (the Weierstrass approximation theorem applied to $\psi^{(d)}$, followed by d integrations from 0 with the initial values $\psi^{(b)}(0)$), so $\Lambda_K(\psi) = 0$ for every $\psi \in C^\infty(\mathbb{R})$ and every large K. A test function ϕ on $(0,\infty)$ is $t^K\psi$ with $\psi = t^{-K}\phi$, smooth with compact support in $(0,\infty)$, and $\langle E,\phi\rangle = \sum_l \int A_l^\dagger\phi\, d\nu_l = \Lambda_K(\psi) = 0$.

(ii) Let $\chi \in C^\infty(\mathbb{R})$ vanish on $(-\infty,1]$ and equal 1 on $[2,\infty)$, put $\chi_\epsilon(t) = \chi(t/\epsilon)$, and let $\tilde\chi$ be a test function equal to 1 on $[\epsilon,R]$. Then $0 = \langle E, t^k\chi_\epsilon\tilde\chi\rangle = \sum_l \int A_l^\dagger(t^k\chi_\epsilon)\, d\nu_l$, the measures being carried by $(0,R]$. The difference $A_l^\dagger(t^k\chi_\epsilon) - \chi_\epsilon A_l^\dagger(t^k)$ involves only the functions $\theta^c\chi_\epsilon(t) = (\theta^c\chi)(t/\epsilon)$ with $c \ge 1$, which are bounded uniformly in ϵ and vanish off $[\epsilon,2\epsilon]$; so it is at most $C\, t^{\operatorname{Re} k}$ on $[\epsilon,2\epsilon]$ and 0 elsewhere, and its integral tends to 0. By dominated convergence $\int \chi_\epsilon A_l^\dagger(t^k)\, d\nu_l \to \int A_l^\dagger(t^k)\, d\nu_l$, so $M_E(k) = 0$. □

Lemma S22. *Let F be real-analytic near $0 \in \mathbb{R}^d$, $d \ge 1$, with $F(0) = 0$, $\nabla F(0) = 0$ and $\nabla^2 F(0) = H$ positive definite, and let w be real-analytic near 0.*

(i) There are $\epsilon > 0$ and a function A holomorphic at 0 with $\int_{\{F\le\sigma\}\cap B_\epsilon} w\, dy = \sigma^{\frac d2} A(\sigma)$ for small $\sigma > 0$, B_ϵ the ball of radius ϵ, and $A(0) = w(0)\,(2\pi)^{\frac d2}\big/\big(\Gamma(\frac d2+1)\sqrt{\det H}\big)$.

(ii) Let F be even and $w = 1$. Then F extends holomorphically to a neighbourhood of 0 in $\mathbb{C}^d$, $F_{\mathbb{T}}(\vartheta) = -F(i\vartheta)$ is real-analytic and even for real ϑ near 0, with the Hessian H at 0, and with the same A, $\int_{\{F_{\mathbb{T}}\le\sigma\}\cap B_\epsilon} d\vartheta = \sigma^{\frac d2} A(-\sigma)$ for small $\sigma > 0$.

Proof. (i) Write $F(y) = \frac12 y^{\mathsf T} Q(y) y$ with $Q(y) = 2\int_0^1 (1-\tau)\nabla^2 F(\tau y)\, d\tau$, symmetric, real-analytic, $Q(0) = H$; near 0, $Q(y)$ has an analytic positive square root, and $v(y) = Q(y)^{1/2} y$ is an analytic change of coordinates with $F = \frac12|v|^2$ and $\partial v/\partial y(0) = H^{1/2}$ (the Morse lemma). With $J(v) = w(y(v))\,|\det \partial y/\partial v| = \sum_\beta J_\beta v^\beta$, convergent on a ball, $J(0) = w(0)(\det H)^{-1/2}$, and for ϵ small the set $\{F \le \sigma\} \cap B_\epsilon$ is the preimage of the ball $|v|^2 \le 2\sigma$ for small σ. The monomials of odd degree integrate to 0 over the ball, and $\int_{|v|^2\le 2\sigma} v^\beta dv = c_\beta (2\sigma)^{\frac{d+|\beta|}{2}}$, so the integral is $\sigma^{\frac d2}\sum_m \big(\sum_{|\beta|=2m} J_\beta c_\beta 2^{\frac d2+m}\big)\sigma^m$, with the series convergent for small σ; at $m = 0$, c_0 is the volume $\pi^{\frac d2}/\Gamma(\frac d2+1)$ of the unit ball.

(ii) F is even, so $\nabla^2 F$ and Q are even and v is odd, with real Taylor coefficients in the monomials of odd degree; its inverse $y(v)$ is odd too, and J is even. A function analytic near 0 extends holomorphically to a polydisc, and $F(i\vartheta)$ is real for real ϑ since only even monomials occur, $i^{2m} = (-1)^m$. Put $v_{\mathbb{T}}(\vartheta) = -i\, v(i\vartheta)$, real for real ϑ since only odd monomials occur, $-i\cdot i^{2m+1} = (-1)^m$. Then $\frac12|v_{\mathbb{T}}|^2 = \frac12(-i)^2\, v(i\vartheta)\cdot v(i\vartheta) = -F(i\vartheta) = F_{\mathbb{T}}(\vartheta)$, and $v_{\mathbb{T}}$ is an analytic change of coordinates with the inverse $\vartheta = -i\, y(i\, v_{\mathbb{T}})$, whose Jacobian matrix is $(\partial y/\partial v)(i\, v_{\mathbb{T}})$; so $d\vartheta = J(i\, v_{\mathbb{T}})\, dv_{\mathbb{T}}$ with $J(iv) = \sum_\beta J_\beta i^{|\beta|} v^\beta = \sum_\beta (-1)^{|\beta|/2} J_\beta v^\beta$, $|\beta|$ even. The computation of (i) gives $\sigma^{\frac d2}\sum_m (-1)^m\big(\sum_{|\beta|=2m} J_\beta c_\beta 2^{\frac d2+m}\big)\sigma^m = \sigma^{\frac d2} A(-\sigma)$. The Hessian of $F_{\mathbb{T}}$ at 0 is $-i^2 H = H$. □

Lemma S23. *(i) Let (z_c,τ_c), $c=1,\dots,m$, be distinct pairs with $|z_c|=1$ and $\tau_c\in\mathbb{R}$, and $a_c\in\mathbb{C}$. If $\sum_c a_c z_c^k\, k^{i\tau_c}\to 0$ as $k\to\infty$ through the integers, every a_c is 0.*

(ii) Let $F(k)=\sum a_{z,\mu,j}\, z^k k^{-\mu}(\log k)^j$ be a finite sum over distinct triples with $|z|=1$, $\mu\in\mathbb{C}$ and $j\in\mathbb{N}$. If $F(k)=O(k^{-N})$ along the integers for some $N>\max \operatorname{Re}\mu$, every $a_{z,\mu,j}$ is 0.

Proof. (i) Let $x_k=\sum_c a_c z_c^k k^{i\tau_c}$ and take the logarithmic means $W_M=\frac{1}{\log M}\sum_{k=1}^M |x_k|^2/k$, which tend to 0 when $x_k\to 0$. In $|x_k|^2$ the term of (c,c') is $a_c\bar a_{c'} w^k k^{i\Delta}$ with $w=z_c\bar z_{c'}$ and $\Delta=\tau_c-\tau_{c'}$. For $c=c'$ it contributes $|a_c|^2\frac{1}{\log M}\sum_{k\le M}\frac{1}{k}\to|a_c|^2$. If $w\neq 1$, the partial sums of w^k are bounded by $2/|1-w|$ and $k\mapsto k^{i\Delta-1}$ has bounded total variation, $|(k+1)^{i\Delta-1}-k^{i\Delta-1}|\le(1+|\Delta|)k^{-2}$; summation by parts bounds $\sum_{k\le M} w^k k^{i\Delta-1}$ uniformly in M. If $w=1$, then $\Delta\neq 0$ and $\sum_{k\le M}k^{i\Delta-1}=\int_1^M x^{i\Delta-1}dx+O(1)=(M^{i\Delta}-1)/(i\Delta)+O(1)$ is bounded. Divided by $\log M$ these tend to 0, so $W_M\to\sum_c|a_c|^2$, and every a_c vanishes.

(ii) Let σ_0 be the least $\operatorname{Re}\mu$ among the triples with $a\neq 0$ and j_0 the largest j among those with $\operatorname{Re}\mu=\sigma_0$. Then $k^{\sigma_0}(\log k)^{-j_0}F(k)$ is $\sum a_{z,\mu,j_0} z^k k^{-i\operatorname{Im}\mu}$, over $\operatorname{Re}\mu=\sigma_0$, plus terms that tend to 0, and it tends to 0 itself since $N>\sigma_0$; the pairs $(z,-\operatorname{Im}\mu)$ are distinct, so (i) makes these a vanish, against the choice of σ_0 and j_0. □

Lemma S24. *Let $\mathbf{p}=(p_0,\dots,p_h)$ be as in Definition 40.4, $D\ge 1$, and $\lambda\neq 0$ a simple root of χ. Consider formal sums $\mathcal{S}=\sum a_{\mu,j}k^\mu(\log k)^j$ over $j\le J$ and μ in finitely many classes modulo $\mathbb{Z}$ with $\operatorname{Re}\mu$ bounded above, with the operator $L=\sum_i p_i(k)\lambda^i\varsigma^i$, where $\varsigma^i\big(k^\mu(\log k)^j\big)=k^\mu(1+\frac{i}{k})^\mu\big(\log k+\log(1+\frac{i}{k})\big)^j$ is expanded in powers of k^{-1}. If $L\mathcal{S}=0$, then $\mathcal{S}=a\,k^\rho\big(1+\sum_{m\ge1}e_m k^{-m}\big)$ with $\rho=-\chi_1(\lambda)/(\lambda\chi'(\lambda))$, $a\in\mathbb{C}$, and e_m fixed by $\mathbf{p}$ and λ; and this series is a formal solution.*

Proof. Each coefficient of $L\mathcal{S}$ is a finite sum, since L raises the exponent by at most D and ς does not raise it. With $p_i=c_ik^D+c_i'k^{D-1}+O(k^{D-2})$ and $\varsigma^i(k^\mu(\log k)^j)=k^\mu(\log k)^j+i\mu\,k^{\mu-1}(\log k)^j+ij\,k^{\mu-1}(\log k)^{j-1}+\cdots$, the dots of lower exponent,

$$L\big(k^\mu(\log k)^j\big)=\chi(\lambda)k^{\mu+D}(\log k)^j+\big(\mu\lambda\chi'(\lambda)+\chi_1(\lambda)\big)k^{\mu+D-1}(\log k)^j \\ +j\lambda\chi'(\lambda)k^{\mu+D-1}(\log k)^{j-1}+\cdots,$$

using $\sum_i c_i i\lambda^i=\lambda\chi'(\lambda)$, and $\chi(\lambda)=0$. Let σ be the largest $\operatorname{Re}\mu$ in $\mathcal{S}$ and, for μ with $\operatorname{Re}\mu=\sigma$, j_μ the largest j with $a_{\mu,j}\neq 0$. No term of $\mathcal{S}$ has an exponent $\mu+r$, $r\ge1$, so the coefficient of $k^{\mu+D-1}(\log k)^{j_\mu}$ in $L\mathcal{S}$ is $a_{\mu,j_\mu}(\mu\lambda\chi'(\lambda)+\chi_1(\lambda))$, and $\mu=\rho$. The coefficient of $k^{\rho+D-1}(\log k)^{j_\rho-1}$ is then $j_\rho\lambda\chi'(\lambda)a_{\rho,j_\rho}$, so $j_\rho=0$: the terms of $\mathcal{S}$ of largest real exponent are $a\,k^\rho$. For the series $k^\rho\sum_m e_m k^{-m}$, $e_0=1$, the coefficient of $k^{\rho-M+D-1}$ in L of it is $-M\lambda\chi'(\lambda)e_M$ plus a combination of $e_0,\dots,e_{M-1}$, which fixes e_M; so it is a formal solution, and $\mathcal{S}-a\,k^\rho\sum_m e_m k^{-m}$ is a formal solution whose terms all have $\operatorname{Re}\mu<\operatorname{Re}\rho$, hence 0 by what precedes. □

Lemma S25. *Let $\mathcal{D}=\sum_{j=0}^D b_j(s)\,\partial_s^j$ have polynomial coefficients with $b_{D,0}=0$, and let $u=\sum_r u_r s^r$ be holomorphic near $s=0$. Then, with $\mathbf{1}_+=\mathbf{1}_{s>0}$ and p_r as in Theorem 40.6(iv),*

$$\mathcal{D}(u\,\mathbf{1}_+)=(\mathcal{D}u)\,\mathbf{1}_+ +\sum_{r=0}^{D-2}\mathsf{p}_r(u)\,\delta^{(D-2-r)},$$

and the coefficient of u_r in $\mathsf{p}_r(u)$ is $r!\,\big(b_{D-1,0}-(D-1-r)\,b_{D,1}\big)$.

Proof. For $i<j$, $\partial^j(s^i\mathbf{1}_+)=i!\,\delta^{(j-1-i)}$, and the Taylor remainder of order j of u times $\mathbf{1}_+$ has the classical j-th derivative; so $\partial^j(u\mathbf{1}_+)=(\partial^j u)\mathbf{1}_+ +\sum_{i<j} i!\,u_i\,\delta^{(j-1-i)}$. Further $s^l\delta^{(m)}=$

$(-1)^l[m]_l\,\delta^{(m-l)}$ for $l \le m$ and 0 for $l > m$, with $[m]_l = \binom{m}{l}\,l!$. So the term $b_{j,l}s^l\partial^j$ sends $u_i\,s^i$, $i<j$, to $(-1)^l\binom{j-1-i}{l}\,i!\,l!\,b_{j,l}\,u_i\,\delta^{(j-1-i-l)}$. The level $r = D-2-(j-1-i-l)$ has $l = j+r+1-D-i$, and $l \le j-1-i$ exactly when $r \le D-2$; $l \ge 0$ and $j \le D$ give $i \le r+1$, with $i = r+1$ only for $j = D$, $l = 0$, excluded by $b_{D,0} = 0$. At $i = r$ the terms are $j = D-1$, $l = 0$, giving $r!\,b_{D-1,0}$, and $j = D$, $l = 1$, giving $-(D-1-r)\,r!\,b_{D,1}$. □

Definition 40.1 (The stride's law). As stated.

Proof. The density of the origin form, $\alpha^{\mathbf{m}_0}\prod_j K_j^{-s_{0j}}\Psi_j^{-t_{0j}}$ with real data, is positive on the positive orthant, the letters being positive there; so ω_0 is a positive measure on the chart and its image under the measurable map $y \mapsto f(e^y)$ is a measure on $(0,\infty)$. □

Proposition 40.2 (A ray is one Trailmoment on a line and one Gramma). *As stated.*

Proof. (i) By Theorem 38.14(i), $0 < f \le f^\star$ on the chart and $f \le C'e^{-c'\|y\|}$, so $\{f \ge t\}$ is compact for $t > 0$ and carries a finite mass of the continuous density ω_0/dy; μ_f is carried by $(0, f^\star]$. For the image measure $\int t^k\mu_f(dt) = \int f^k\omega_0 = \langle 1\rangle_k$, the integrals converging absolutely together. With the kernel $\mathsf{Z}_{k;(1)}(x) = x^{-k}$ (Definition 5.2) the Trailmoment of the input μ_f (Definition 5.4) with the coefficient function t^{-1} over $(0,\infty)$ is $\int t^k\mu_f(dt)$, and Theorem 5.9 with $\tau = \iota$ writes it as $(\mathsf{T}_{k;(1)}[x]\,\iota_*\mu_f)((0,\infty))$.

(ii) If 0 were not an interior point of the cone of $\mathbf{v}$, a nonzero y would have $\langle \mathbf{v}_i, y\rangle \le 0$ for every i (the separation of a point from a closed convex cone), and then $f^{-1}(e^{\lambda y}) \le \sum_i w_i$ for $\lambda > 0$, against $f \le C'e^{-c'\|y\|}$; so the cone is $\mathbb{R}^{\mathcal{E}\setminus e_0}$, and Theorem 2.2 makes the Gramma entire. For $X > 0$ and $\operatorname{Re} k > 0$, $\Gamma(k)X^{-k} = \int_0^\infty u^{k-1}e^{-uX}du$. At $X = f^{-1}$, integrated against $\omega_0 = \alpha^{\mathbf{m}_0}dy$, Fubini's theorem applies, the double integral of the modulus being $\Gamma(\operatorname{Re} k)\langle 1\rangle_{\operatorname{Re} k}$ at real data, and the inner integral is $\int_{\mathbb{R}^{\mathcal{E}\setminus e_0}_{>0}} x^{\mathbf{m}_0|_{\mathcal{E}\setminus e_0}-\mathbf{1}}\exp\big(-\sum_i uw_ix^{\mathbf{v}_i}\big)dx = \mathsf{G}_{\mathbf{m}_0|_{\mathcal{E}\setminus e_0};\mathbf{v}}(u\mathbf{w})$ (Definition 2.1), $\alpha^{\mathbf{m}_0}$ being $x^{\mathbf{m}_0|_{\mathcal{E}\setminus e_0}}$ on the chart. This is Theorem 5.11 for the Trailmoment of (i), whose Laplace transform beyond the cut 0 is $\int e^{-ux}\,\iota_*\mu_f(dx) = \int e^{-uf^{-1}}\omega_0$.

(iii) The shape law has the density $u^{\mathbf{m}-\mathbf{1}}\prod_j K_j(u)^{-s_j}\Psi_j(u)^{-t_j}$ against $d\omega_{\mathcal{E}}$, divided by the period (Definition 8.10), and the change of variables of Theorem 8.7 that carries the period to the chart, $\langle 1\rangle_k = \int f^k\omega_0$ (Lemma S20(iv)), carries the expectation of every bounded measurable function φ of degree 0 to $\int \varphi\,f^k\omega_0/\langle 1\rangle_k$. At $\varphi = \psi\circ f$ this is $\int \psi(t)\,t^k\mu_f(dt)/\langle 1\rangle_k$. So $\log\langle 1\rangle_k = \log\int t^k\mu_f(dt)$ is the log-partition of the family $t^k\mu_f(dt)/\langle 1\rangle_k$; it is real-analytic in k, and differentiation under the integral gives the first derivative $\mathbb{E}[\log f(U)]$ and the second $\mathbb{E}[\log^2 f(U)] - \mathbb{E}[\log f(U)]^2$, which is positive because $\log f(U)$ is not almost surely constant: U has a positive continuous density on the chart, and f is continuous there and not constant, $f(\alpha^\star) = f^\star > 0$ while $f \le C'e^{-c'\|y\|}$ (Theorem 38.14(i)). □

Proposition 40.3 (The two ends of the stride's law). *As stated.*

Proof. (i) At $y = 2z$ the stride is $e^{X_1(z)}$, X_1 the exponent of the question of the direction (proof of Lemma S20(ii)), and $-X_1$ is strictly convex (Theorem 17.5(ii)); so $\log f$ is strictly concave on the chart, its only critical point is its maximum $\log\alpha^\star$, and $\nabla f \ne 0$ elsewhere. For $0 < t < f^\star$ the level set $\Sigma_t = \{f = t\}$ is then a compact real-analytic hypersurface, compact because $f \to 0$ at infinity of the chart, and not empty, the chart being connected. Near $t_1 \in (0, f^\star)$ the flow Φ of the real-analytic field $\nabla f/|\nabla f|^2$, along which f grows at the unit rate, maps $\Sigma_{t_1}\times(t_1-\epsilon, t_1+\epsilon)$ real-analytically onto a neighbourhood of Σ_{t_1}, with $f(\Phi(x,\tau)) = \tau$, and $dy = J(x,\tau)\,d\sigma(x)\,d\tau$ with J real-analytic and positive. So μ_f has the density $\varrho_f(\tau) = \int_{\Sigma_{t_1}}(\omega_0/dy)(\Phi(x,\tau))\,J(x,\tau)\,d\sigma(x)$ there, real-analytic and positive; this is the coarea formula.

(ii) Apply Lemma S22(i) to $F(y) = \log f^\star - \log f(e^y)$ at $\log \alpha^\star$, with the Hessian H, positive definite (Lemma S20(iii)), and $w = \omega_0/dy$. Since $f < f^\star - \delta'$ off a neighbourhood of $\log \alpha^\star$, $\mu_f([t, f^\star]) = \int_{\{F \le L\} \cap B_\epsilon} w\, dy = L^{\frac{n-1}{2}} A(L)$ for t near $f^\star$, with $L = \log(f^\star/t)$. Differentiating, with $dL/dt = -1/t$,

$$\varrho_f(t) = -\frac{d}{dt}\mu_f([t, f^\star]) = \frac{1}{t}\, L^{\frac{n-3}{2}} B(L), \qquad B(L) = \tfrac{n-1}{2} A(L) + L A'(L).$$

Put $\lambda(t) = L/(f^\star - t)$, holomorphic and positive near $f^\star$ with $\lambda(f^\star) = 1/f^\star$. Then $\varrho_f(t) = (f^\star - t)^{\frac{n-3}{2}} g(f^\star - t)$ with $g(f^\star - t) = t^{-1}\lambda(t)^{\frac{n-3}{2}} B(L)$, holomorphic at $t = f^\star$, and $g(0) = (f^\star)^{-\frac{n-1}{2}} \frac{n-1}{2} A(0)$; with $A(0)$ from Lemma S22(i) at $d = n-1$ and $\frac{n-1}{2}/\Gamma(\frac{n+1}{2}) = 1/\Gamma(\frac{n-1}{2})$ this is the stated value.

(iii) By Proposition 17.4(i) for the question of the direction, $2\kappa(z) + \sum_j (s_{1j} + t_{1j}) \log \theta_{j,\min} \le -X_1(z) \le 2\kappa(z) + \sum_j (s_{1j} + t_{1j}) \log K_j(\mathbf{1})$, and $2\kappa(y/2) = \kappa(y)$, κ being positively homogeneous of degree one; with $\log f(e^y) = X_1(y/2)$ this is the squeeze. On the sector of an order π (Definition 17.3) the differences $u_l = y_{\pi(l-1)} - y_{\pi(l)} \ge 0$, $2 \le l \le n$, are coordinates in which dy is the Lebesgue measure and $\kappa(y) = \sum_l \kappa_{1,U_l} u_l$, so $\int_{\text{sector}} e^{-\kappa} dy = \prod_l \kappa_{1,U_l}^{-1}$; the sectors cover the chart and meet in null sets, so $\int e^{-\kappa} dy = V_1$. By homogeneity $\operatorname{vol}\{\kappa \le \sigma\} = \sigma^{n-1} \operatorname{vol}\{\kappa \le 1\}$ and $V_1 = \int_0^\infty e^{-\sigma}\, d\operatorname{vol}\{\kappa \le \sigma\} = (n-1)! \operatorname{vol}\{\kappa \le 1\}$, as in Theorem 17.5(i). For $t \le C_-$ the squeeze gives $\{\kappa \le \log(C_-/t)\} \subseteq \{f \ge t\} \subseteq \{\kappa \le \log(C_+/t)\}$, and $\mu_f([t, f^\star]) = \operatorname{vol}\{f \ge t\}$ for the origin 0. Last, $\int e^{-k\kappa} dy = k^{1-n} V_1$ for $k > 0$, by homogeneity, and $C_-^k e^{-k\kappa} \le f^k \le C_+^k e^{-k\kappa}$. □

Definition 40.4 (The density operator of a recurrence). As stated.

Proof. For a polynomial p of degree at most D, $p(-1-i-\theta) = c(-1)^D \theta^D + \cdots$ with $c = [k^D]p$, and $\theta^D = t^D \partial^D + \cdots$; so the coefficient of ∂^D in $t^i p_i(-1-i-\theta)$ is $(-1)^D c_i t^{D+i}$, and $a_D = (-1)^D t^D \chi(t)$. Extension by zero involves only u near λ: two intervals give the same condition on their common part, $\mathfrak{D}_{\mathbf{p}}$ being a differential operator. □

Proposition 40.5 (A recurrence of the values is an equation for the density). *As stated.*

Proof. Let k_* be the bound beyond which $\langle 1 \rangle_k$ converges absolutely, $\operatorname{Re} k > k_*$ (Lemma S20(iv)), and $K_0 > k_*$. Apply Lemma S21 to $\nu_1 = \mu_f$, carried by $(0, f^\star]$ with $\int t^{K_0} d\mu_f = \langle 1 \rangle_{K_0} < \infty$, and $A_1 = \mathfrak{D}_{\mathbf{p}}$, for which $A_1^\dagger t^k = \sum_i p_i(k) t^{k+i}$ and $M_E(k) = \sum_i p_i(k) \langle 1 \rangle_{k+i}$, $E = \mathfrak{D}_{\mathbf{p}} \mu_f$. (a) gives (c) by Lemma S21(i), and (c) gives the vanishing for $\operatorname{Re} k \ge K_0$ by (ii), for every $K_0 > k_*$. By Proposition 38.5(ii) the values continue meromorphically to $\mathbb{C}$, so the identity holds as one of meromorphic functions, and at every k where its terms converge; (b) gives (a).

On $(0, f^\star)$, $\mu_f = \varrho_f\, dt$ with ϱ_f real-analytic (Proposition 40.3(i)), so E restricted there is $(\mathfrak{D}_{\mathbf{p}} \varrho_f)\, dt$, and (c) gives $\mathfrak{D}_{\mathbf{p}} \varrho_f = 0$. On $(f^\star - \delta, f^\star + \delta)$, $\mu_f = \varrho_f \mathbf{1}_{(f^\star - \delta, f^\star)} dt$, the point $f^\star$ having no mass, and ϱ_f is integrable there by Proposition 40.3(ii), $\frac{n-3}{2} > -1$; so the germ extends by zero. For the origin 0, the proof of Corollary 39.38(i) and (ii) uses of $p_0, \dots, p_h$ only that the identity holds as one of meromorphic functions, with Proposition 39.35(ii) at $k = -j$ and at $k = 0$, $\mathsf{L}_0 = V_1 \ne 0$ (Definition 39.37). □

Theorem 40.6 (The gauge end). *As stated.*

Proof. (i) If $D = 0$, every p_i is a constant c_i, $\mathfrak{D}_{\mathbf{p}}$ is the multiplication by $\chi(t)$, not identically zero, and $\chi \varrho_f = 0$ on $(0, f^\star)$ (Proposition 40.5) contradicts $\varrho_f > 0$. So $D \ge 1$. With $b_j(s) = (-1)^j a_j(f^\star - s)$, $b_D(s) = (f^\star - s)^D \chi(f^\star - s)$, so $b_{D,0} = 0$ and $b_{D,1} = -(f^\star)^D \chi'(f^\star)$. Write

$p_i = c_i k^D + c_i' k^{D-1} + \cdots$; $p_i(-1-i-\theta) = (-1)^D c_i\big(\theta^D + D(1+i)\theta^{D-1}\big) + (-1)^{D-1} c_i' \theta^{D-1} + \cdots$, and $\theta^m = t^m\partial^m + \binom{m}{2} t^{m-1}\partial^{m-1} + \cdots$; so

$$a_{D-1} = (-1)^D t^{D-1}\Big(\big(\tbinom{D}{2} + D\big)\chi(t) + D\,t\,\chi'(t) - \chi_1(t)\Big),$$
$$b_{D-1,0} = -(f^\star)^{D-1}\big(D f^\star \chi'(f^\star) - \chi_1(f^\star)\big),$$

which gives the two forms of γ. Since $s^j\partial_s^j = [s\partial_s]_j$, $s^{D-1}\mathfrak{D}_{\mathbf{p}} = \sum_{j,l} b_{j,l} s^{l+D-1-j}[s\partial_s]_j$; the exponent $m = l + D - 1 - j$ is nonnegative, as $l \geq 1$ for $j = D$, and the terms with $m = 0$ are $(j,l) = (D-1, 0)$ and $(D, 1)$, which give R_0. So $s = 0$ is a regular singular point, R_0 having the degree D of the operator, and its exponents are the roots of R_0.

(ii) Let u extend by zero on $(f^\star - \delta, f^\star)$. By Fuchs's theorem on regular singular points, which applies by (i), $u = \sum_{\lambda,j} s^\lambda (\log s)^j h_{\lambda,j}(s)$ near $s = 0^+$, a finite sum with λ among the exponents, $j \leq D$ and $h_{\lambda,j}$ holomorphic at 0; so u has a convergent expansion $\sum c_{\mu,j} s^\mu (\log s)^j$, $\mu \in \{0, \dots, D-2, \gamma\} + \mathbb{N}$, and integrability forces $\operatorname{Re}\mu > -1$ for its terms: the terms of least real part $\operatorname{Re}\mu$ and largest j are $s^{\operatorname{Re}\mu}(\log s)^j$ times a trigonometric polynomial in $\log s$, not identically 0, whose modulus has a positive mean, and this is not integrable at 0 when $\operatorname{Re}\mu \leq -1$. Fix ψ smooth, 0 on $(-\infty, f^\star - \frac{2}{3}\delta]$ and 1 on $[f^\star - \frac{1}{3}\delta, \infty)$, and put $T = \psi\, u\, \mathbf{1}_{(f^\star-\delta, f^\star)}$. On $(f^\star - \delta, f^\star + \delta)$, $\mathfrak{D}_{\mathbf{p}} T = \psi\, \mathfrak{D}_{\mathbf{p}}(u\mathbf{1}) + \sum_{a\geq 1}(\dots)\psi^{(a)}$, where the first term vanishes and the others are smooth functions carried by $[f^\star - \frac{2}{3}\delta, f^\star - \frac{1}{3}\delta]$, where u is real-analytic; so $\mathfrak{D}_{\mathbf{p}} T = \mathcal{E}$ is a smooth function with that support, and, T having compact support in $(0, \infty)$,

$$\sum_i p_i(k)\, M(k+i) = \int t^k\, \mathcal{E}(t)\, dt = O\big((f^\star - \tfrac{1}{3}\delta)^k\big), \qquad M(k) = \int t^k T(t)\, dt,$$

for real $k \to \infty$. In $t = f^\star e^{-\sigma}$, $M(k) = f^\star (f^\star)^k \int_0^\infty e^{-(k+1)\sigma}\, T(f^\star e^{-\sigma})\, d\sigma$, and $s = f^\star(1 - e^{-\sigma}) = f^\star\sigma(1 + O(\sigma))$; so near $\sigma = 0$, $T(f^\star e^{-\sigma})$ is a convergent sum of $\sigma^\mu(\log\sigma)^j$ times holomorphic functions, with the same leading terms as u up to the factors $(f^\star)^\mu$, and the part away from 0 contributes $O\big((f^\star - \frac{1}{3}\delta)^k\big)$. Watson's lemma with logarithms, $\int_0^c e^{-\kappa\sigma}\sigma^\mu(\log\sigma)^j d\sigma = \partial_\mu^j\big[\Gamma(\mu + 1)\kappa^{-\mu-1}\big] + O(e^{-c\kappa/2})$ for $\operatorname{Re}\mu > -1$, gives $A(k) = (f^\star)^{-k} M(k)$ an asymptotic expansion $\mathcal{S}_u = \sum a_{\mu,j} k^{-\mu-1}(\log k)^j$ along the integers, in finitely many classes of exponents and with $\operatorname{Re}\mu$ bounded below. Its leading terms are $f^\star(f^\star)^\mu c_{\mu,j_0}\Gamma(\mu+1)(-1)^{j_0} k^{-\mu-1}(\log k)^{j_0}$, over the μ of least real part and the largest j_0 among them, with $\Gamma(\mu+1) \neq 0$; by Lemma S23(ii) they do not cancel, so $\mathcal{S}_u \neq 0$ when $u \neq 0$. Applying the recurrence to truncations of the expansion, $\sum_i p_i(k)(f^\star)^i A(k+i) = O(r^k)$, $r < 1$, and Lemma S23(ii), order by order, give $L\mathcal{S}_u = 0$ with $L = \sum_i p_i(k)(f^\star)^i \varsigma^i$, so by Lemma S24, $\mathcal{S}_u$ is a multiple of one fixed series. The map $u \mapsto \mathcal{S}_u$ is linear and injective, so the germs that extend by zero form a space of dimension at most one.

(iii) By Proposition 40.5 the germ of ϱ_f extends by zero, and it is not zero; so it spans the space of (ii). Put $a = \frac{n-3}{2}$; by Proposition 40.3(ii), $\varrho_f = s^a g(s)$ with $g(0) \neq 0$, and it solves $\mathfrak{D}_{\mathbf{p}}$ on $s > 0$. If $a \notin \mathbb{Z}$, the leading coefficient of $s^{D-1}\mathfrak{D}_{\mathbf{p}}(s^a g) = \sum_m s^m R_m(s\partial_s)(s^a g)$ is $R_0(a)g(0)$, so a is a root of R_0 other than $0, \dots, D-2$, and $a = \gamma$. If $a \in \mathbb{N}$, ϱ_f is holomorphic at $s = 0$, with $u_r = 0$ for $r < a$ and $u_a = g(0)$. When $a \leq D-2$, the germ extends by zero, and by Lemma S25 $\mathsf{p}_a(\varrho_f) = a!\, b_{D,1}(a - \gamma)\, g(0) = 0$, the lower coefficients vanishing; so $\gamma = a$. When $a \geq D-1$, the coefficient of s^a in $s^{D-1}\mathfrak{D}_{\mathbf{p}}\varrho_f = 0$ is $R_0(a)g(0)$, so a is a root of R_0 and again $\gamma = a$.

(iv) If $\gamma \notin \{0, \dots, D-2\}$, then $\gamma = a$ is not an integer or is an integer at least $D-1$, and in both cases $R_0(\gamma + N) \neq 0$ for $N \geq 1$, the roots of R_0 being $0, \dots, D-2$ and γ. Inserting $s^\gamma \sum_N g_N s^N$ into $\sum_m s^m R_m(s\partial_s)$ and using $s\partial_s(s^{\gamma+N}) = (\gamma + N)s^{\gamma+N}$, the coefficient of $s^{\gamma+N}$ is $\sum_{m\leq N} R_m(\gamma + N - m) g_{N-m}$; its vanishing is the stated recurrence, so $g = g(0)\Phi$. If $\gamma \in$

$\{0,\dots,D-2\}$, then by (iii) ϱ_f is holomorphic at $s=0$ with $u_r=0$ for $r<\gamma$ and $u_\gamma=g(0)$; it extends by zero, so $\mathsf{p}_r(\varrho_f)=0$ for $r\le D-2$ (Lemma S25, the distributions $\delta^{(q)}$ being linearly independent), and for $\gamma<r\le D-2$ the coefficient $r!\,b_{D,1}(r-\gamma)$ of u_r is not 0, so these equations fix u_r from the lower coefficients. For $N\ge D-1$, $R_0(N)\neq 0$, and the coefficient of s^N in $s^{D-1}\mathfrak{D}_{\mathbf{p}}\varrho_f$ gives the last recurrence.

(v) Each point of $(0,f^\star)$ has a disc in $\mathbb{C}$ to which ϱ_f extends holomorphically (Proposition 40.3(i)); two such discs meet in a convex set that meets the real line, so the extensions agree there, and they define a holomorphic function on the union U, on which $\mathfrak{D}_{\mathbf{p}}\varrho_f=0$ by the identity theorem. The germ at $f^\star$ is that of (iv), and its continuation along a path in U that follows $(0,f^\star)$ is ϱ_f; near a root of χ on the segment, ϱ_f is holomorphic, so the continuations around it on either side agree. For $\operatorname{Re}k>k_*$, $t^k(\log t)^j$ is dominated on $(0,f^\star]$ by $C\,t^K$ for every K with $k_*<K<\operatorname{Re}k$, locally uniformly in k, so the derivatives pass under $\int t^k\mu_f(dt)$. □

Proposition 40.7 (The law knows the dimension of its chart). *As stated.*

Proof. Let α_c be the native gauge with $f(\alpha_c)=\lambda$ and A_c its solution (Theorem 38.6, Definition 39.2). The class of $\sum_i p_i(k)f^i$ in $\mathfrak{M}$ is $\sum_i p_i(k)\,\mathrm{Sh}^i[1]=0$, so $\sum_i p_i(k)\varsigma^iA_c[1]=0$, and $\lambda^{-k}A_c[1]=k^{-\frac{n-1}{2}}\big(a_0(1)+\cdots\big)$ with $a_0(1)=(2\pi)^{\frac{n-1}{2}}(\omega_0/dv)(\alpha_c)\neq 0$ is a formal solution of $L=\sum_i p_i(k)\lambda^i\varsigma^i$. By Lemma S24 every formal solution is a multiple of $k^{\rho_\lambda}\big(1+\sum_m e_mk^{-m}\big)$, and comparing leading exponents, $\rho_\lambda=-\frac{n-1}{2}$. The computation of Theorem 40.6(i) uses of $f^\star$ only that it is a simple nonzero root of χ, so at λ the point $s=0$ is regular singular with the exponents $0,\dots,D-2$ and $-1+\chi_1(\lambda)/(\lambda\chi'(\lambda))=-1-\rho_\lambda=\frac{n-3}{2}$. □

Proposition 40.8 (The germ at the gauge end is local data at the native gauge). *As stated.*

Proof. (i) The potential of the realization is $\Phi(y)=\sum_j\big(s_{1j}\log K_j(e^y)+t_{1j}\log\Psi_j(e^y)\big)$ (Definition 8.18) and $\log f(e^y)=\langle\mathbf{m}_1,y\rangle-\Phi(y)$, so for $m\ge 2$ the Taylor tensor of $\log f$ is $-\partial^m\Phi=-2^{-m}\kappa_\Upsilon$ (Definition 9.4), and Proposition 9.6 at $y_0=\log\alpha^\star$ gives the cumulants.

(ii) Put $\eta(y)=\log f-\log f^\star+\frac12H_{ab}y^ay^b$, of order three. Outside a ball $|y|<\epsilon$ the stride is at most $f^\star e^{-c}$, so that part of $\langle1\rangle_k$ is $O\big((f^\star e^{-c})^{k-1}\langle1\rangle_1\big)$. Inside, with $y=v/\sqrt{k}$, $\langle1\rangle_k=(f^\star)^kk^{-\frac{n-1}{2}}\int_{|v|<\epsilon\sqrt{k}}e^{-\frac12H_{ab}v^av^b}e^{k\eta(v/\sqrt{k})}dv$, and $k\eta(v/\sqrt{k})=k^{-1/2}h_3(v)+k^{-1}h_4(v)+k^{-3/2}h_5(v)+O(k^{-2}|v|^6)$ with $h_3=\frac16h_{abc}v^av^bv^c$, $h_4=\frac{1}{24}h_{abcd}v^av^bv^cv^d$ and h_5 the quintic term; for ϵ small $|k\eta(v/\sqrt{k})|\le\frac14H_{ab}v^av^b$ on the ball. Expanding the exponential to the order $k^{-3/2}$, with the remainder bounded by $Ck^{-2}(1+|v|)^{12}e^{\frac14Hvv}$, the terms of order $k^{-1/2}$ and $k^{-3/2}$ are odd in v and integrate to 0 over the ball, and extending the Gaussian integrals to $\mathbb{R}^{n-1}$ costs an exponentially small amount. So $\langle1\rangle_k=(f^\star)^k(2\pi/k)^{\frac{n-1}{2}}(\det H)^{-1/2}\big(1+k^{-1}\mathbb{E}[h_4+\frac12h_3^2]+O(k^{-2})\big)$ for the centred Gaussian with covariance G. Its moments are $\mathbb{E}[v^av^bv^cv^d]=G^{ab}G^{cd}+G^{ac}G^{bd}+G^{ad}G^{bc}$ and, for six factors, the sum over the 15 pairings; by the symmetry of h_{abc}, 9 of the pairings of $h_{abc}h_{def}$ join one pair inside each factor and 6 join every index across. So $\mathbb{E}[h_4]=\frac18h_{abcd}G^{ab}G^{cd}$ and $\frac12\mathbb{E}[h_3^2]=\frac{1}{72}\big(9h_{abc}h_{def}G^{ab}G^{cd}G^{ef}+6h_{abc}h_{def}G^{ad}G^{be}G^{cf}\big)$.

(iii) On $(f^\star-\delta,f^\star)$, $\varrho_f=\sum_m g_m(f^\star-t)^{\frac{n-3}{2}+m}$, and $\int_0^{f^\star-\delta}t^k\mu_f(dt)=O\big((f^\star-\delta)^{k-1}\langle1\rangle_1\big)$. For each M, $\int_{f^\star-\delta}^{f^\star}t^k\varrho_f\,dt$ is the sum over $m<M$ of $g_m\int_{f^\star-\delta}^{f^\star}t^k(f^\star-t)^{\frac{n-3}{2}+m}dt$ plus $O\big(\int_0^{f^\star}t^k(f^\star-t)^{\frac{n-3}{2}+M}dt\big)$, and $\int_0^{f^\star}t^k(f^\star-t)^{b-1}dt=(f^\star)^{k+b}\mathrm{B}(k+1,b)$, the part over $(0,f^\star-\delta)$ being exponentially smaller. With $\mathrm{B}(k+1,b)=\Gamma(b)\Gamma(k+1)/\Gamma(k+1+b)=\Gamma(b)k^{-b}(1+O(k^{-1}))$ the term of g_m, $b=\frac{n-1}{2}+m$, begins at $(f^\star)^{k+b}\Gamma(b)g_mk^{-b}$, and the remainder is $O\big((f^\star)^kk^{-\frac{n-1}{2}-M}\big)$. So the expansion of $(f^\star)^{-k}k^{\frac{n-1}{2}}\langle1\rangle_k$ is triangular in the g_m, with the nonzero diagonal $(f^\star)^{\frac{n-1}{2}+m}\Gamma(\frac{n-1}{2}+m)$. □

Proposition 40.9 (Slopes from the gauge end). *As stated.*

Proof. (i) Differentiate j times the identity of meromorphic functions $\sum_i p_i(k)\langle 1\rangle_{k+i} = 0$ (Proposition 40.5) by the Leibniz rule.

(ii) By Theorem 40.6(v), $\partial_k^j \langle 1\rangle_k|_{k=K} = \int_0^{f^\star} t^K (\log t)^j \varrho_f(t)\,dt$, and on $(0, f^\star)$ the series gives $\varrho_f = \sum_m g_m (f^\star - t)^{\frac{n-3}{2}+m}$, convergent there. Let $K' < K'' < K$. On $(0, f^\star]$, $t^K |\log t|^j \le C\, t^{K''}$, so $\sum_m |g_m| \int_0^{f^\star} t^K |\log t|^j (f^\star - t)^{\frac{n-3}{2}+m} dt \le C \sum_m |g_m| (f^\star)^{K''+\frac{n-1}{2}+m} \mathrm{B}\big(K''+1, \frac{n-1}{2}+m\big)$, which is finite because $\mathrm{B}(K''+1, b) \le \mathrm{B}(K'+1, b)$, the Beta function being decreasing in its first argument. So the integral of the sum is the sum of the integrals (Fubini's theorem), and $\int_0^{f^\star} t^a (\log t)^j (f^\star - t)^{b-1} dt = \partial_a^j \big[(f^\star)^{a+b} \mathrm{B}(a+1, b)\big]$, differentiation under the integral being allowed for a near K. □

Definition 40.10 (The procedure that reads a ray from its gauge end). As stated.

Proof. (1) $\log f$ is strictly concave on the positive part of the chart (proof of Proposition 40.3(i)), so its critical point is unique, the native gauge of the direction there (Theorem 38.14(i)). (2) and (3) are Definition 40.4 and Theorem 40.6(i), (iii) and (iv); the coefficients $b_{j,l}$ lie in $\Bbbk(f^\star)$, and so do the ratios u_r/u_γ and Φ_N. (4) $\epsilon_k = \int_{(0, f^\star - \delta)} t^k \mu_f(dt)$ is nonnegative and, for real $k' \le k$, at most $(f^\star - \delta)^{k-k'} \int t^{k'} \mu_f(dt)$; the bound on $\langle 1\rangle_{k'}$ is Proposition 40.3(iii). On $[f^\star - \delta, f^\star]$, ϱ_f is its germ, by Theorem 40.6(iv). (5) The recurrence holds at every positive integer (Proposition 40.5), and $\langle 1\rangle_k = -\sum_{i\ge 1} p_i(k)\langle 1\rangle_{k+i}/p_0(k)$ where $p_0(k) \ne 0$; the values are moments of ϱ_f by Theorem 40.6(v). (6) is Proposition 40.9, and (7) is Corollary 39.38(ii), which holds for $\mathbf{p}$ by Proposition 40.5. □

Definition 40.11 (The torus value). As stated.

Proof. On $\mathbb{T}$, $\alpha^{-1} = \bar\alpha$, and the letters have real coefficients, so $K_j(\alpha^{-1}) = \overline{K_j(\alpha)}$ and $f = \prod_j |K_j(\alpha)|^{-2\sigma_j}$; the coefficients being nonnegative, $|K_j(\alpha)| \le K_j(\mathbf{1})$, and $f \ge \prod_j K_j(\mathbf{1})^{-2\sigma_j} = f(\mathbf{1}) = f^\star$, the native gauge of the direction being $\mathbf{1}$ (Theorem 38.14). The zero set of an active letter has measure zero, the letter being a Laurent polynomial that is not zero, so a real-analytic function on the connected torus that is not identically zero, so f is finite almost everywhere and $\nu_f^{\mathbb{T}}$ is a probability measure on $[f^\star, \infty)$. For $\mathrm{Re}\, k \le 0$, $|f^k| = f^{\mathrm{Re}\, k} \le (f^\star)^{\mathrm{Re}\, k}$, read as 0 where $f = \infty$ and $\mathrm{Re}\, k < 0$, so the integral converges. When no K_j vanishes on $\mathbb{T}$, $\mathbb{T}$ is a compact cycle in X_F, $\Psi_j(\alpha) = \alpha^{\mathcal{E}} K_j(\alpha^{-1})$ (Proposition 7.2) does not vanish either, and on it $dy = i^{n-1} d\vartheta$, the coordinates being $y_e = i\vartheta_e$. □

Proposition 40.12 (The torus is the second chain). *As stated.*

Proof. (i) Equality $|K_j(e^{i\vartheta})| = K_j(\mathbf{1})$ holds exactly when the numbers $\langle \mathbf{1}_T, \vartheta\rangle$, T the bases of table j, agree modulo 2π, all the coefficients being positive. The active tables form a connected family (Definition 38.13), so one molecule, and for linked marks e, e' some basis T has $e \in T$, $e' \notin T$ and $(T \setminus \{e\}) \cup \{e'\}$ a basis (Lemma 7.7); equality for every active table therefore gives $\vartheta_e \equiv \vartheta_{e'}$ for all marks, and $\alpha = \mathbf{1}$ on the chart. So $f > f^\star$ off $\mathbf{1}$, as in the proof of Theorem 39.57. The function $|K_j(e^{i\vartheta})|^2$ is a trigonometric polynomial, real-analytic and not identically 0 since its value at $\vartheta = 0$ is $K_j(\mathbf{1})^2$; the zero set of such a function on the connected torus has measure zero. For $\mathrm{Re}\, k \le 0$ the integrand is bounded by $(f^\star)^{\mathrm{Re}\, k}$; dominated convergence gives the continuity, and Morera's theorem the holomorphy on $\mathrm{Re}\, k < 0$. At $k = -j$, $f^{-j} = \prod_j |K_j|^{2j\sigma_j}$ is the Laurent polynomial $\prod_j (K_j(\alpha) K_j(\alpha^{-1}))^{j\sigma_j}$ restricted to $\mathbb{T}$, whose mean is its constant term; it is $\mathsf{C}_j(1)$ when every letter exponent of the direction is at least 1 (Definition 39.30).

(ii) The hypotheses of Theorem 39.57 hold for the centre ray with every $\sigma_j \geq 1$, so by Corollary 39.60 $\sum_i p_i(-j)\mathsf{C}_{j-i}(1) = 0$ for all large j, that is, by (i), $\sum_i p_i(k)\langle 1\rangle^{\mathbb{T}}_{k+i} = 0$ at all large negative integers k. With $x = 1/t$, $\nu_f^{\mathbb{T}}$ becomes a probability measure $\tilde\nu$ on $(0, 1/f^\star]$ with no mass at 0, $\theta = -x\frac{d}{dx}$, and $\mathfrak{D}^\dagger_{\mathbf{p}} = \sum_i p_i(\theta - i)\, t^i$ becomes $\tilde A = \sum_i p_i(-x\frac{d}{dx} - i)\, x^{-i}$. For a test function $\phi(t) = x^K\psi(x)$, $\tilde A(x^K\psi) = \sum_i x^{K-i}p_i(-x\frac{d}{dx} - K)\psi$ is bounded on $(0, 1/f^\star]$ by $C_K \max_{b\leq D}\sup|\psi^{(b)}|$ for $K \geq h$, and at $\psi = x^m$ its integral against $\tilde\nu$ is $\sum_i p_i(-K-m)\langle 1\rangle^{\mathbb{T}}_{-K-m+i}$, which vanishes for K large. As in the proof of Lemma S21(i), on $[0, 1/f^\star]$, the Weierstrass approximation theorem gives $\langle \mathfrak{D}_{\mathbf{p}}\nu_f^{\mathbb{T}}, \phi\rangle = \int \tilde A(x^K\psi)\, d\tilde\nu = 0$ for every test function. Conversely, for $\operatorname{Re} k \leq -h$ the functions t^{k+i} are bounded on $[f^\star, \infty)$, and the cutoff argument of Lemma S21(ii), at $x \to 0$ in place of $t \to 0$, gives $\sum_i p_i(k)\langle 1\rangle^{\mathbb{T}}_{k+i} = \int \mathfrak{D}^\dagger_{\mathbf{p}}(t^k)\, d\nu_f^{\mathbb{T}} = 0$, the cutoff terms being bounded and carried by $x \in [\epsilon, 2\epsilon]$, whose mass under $\tilde\nu$ tends to 0.

(iii) The stride is holomorphic and nonzero near $y = 0$ in $\mathbb{C}^{\mathcal{E}\setminus e_0}$, and $F(y) = \log f^\star - \log f(e^y)$ is even, $f(\alpha^{-1}) = f(\alpha)$ on the centre ray (Theorem 38.17(i)), with the Hessian H at 0 positive definite (Lemma S20(iii)). On $\mathbb{T}$, $\log f(e^{i\vartheta}) - \log f^\star = -F(i\vartheta) = F_{\mathbb{T}}(\vartheta)$, real, and by (i) and compactness $f \geq f^\star + \delta'$ on $\mathbb{T}$ off a neighbourhood of $\mathbf{1}$; so for t near $f^\star$, $\nu_f^{\mathbb{T}}([f^\star, t]) = (2\pi)^{1-n}\operatorname{vol}\{F_{\mathbb{T}} \leq \log(t/f^\star)\} \cap B_\epsilon$. By Lemma S22, with $L = \log(f^\star/t)$, $\mu_f([t, f^\star]) = L^{\frac{n-1}{2}}A(L)$ for $t < f^\star$ and $\nu_f^{\mathbb{T}}([f^\star, t]) = (2\pi)^{1-n}(-L)^{\frac{n-1}{2}}A(L)$ for $t > f^\star$, with one A, $w = 1$. Differentiating, with $B = \frac{n-1}{2}A + LA'$, $\varrho_f(t) = t^{-1}L^{\frac{n-3}{2}}B(L)$ and

$$\varrho_f^{\mathbb{T}}(t) = \frac{d}{dt}\Big[(2\pi)^{1-n}(-L)^{\frac{n-1}{2}}A(L)\Big] = (2\pi)^{1-n}\, t^{-1}(-L)^{\frac{n-3}{2}}B(L).$$

With $\lambda(t) = L/(f^\star - t)$, positive near $f^\star$, $L = (f^\star - t)\lambda$ and $-L = (t - f^\star)\lambda$, so both densities carry the factor $t^{-1}\lambda(t)^{\frac{n-3}{2}}B(L)$, which is $g(f^\star - t)$ by the proof of Proposition 40.3(ii).

(iv) By Proposition 40.5 and Theorem 40.6(iii) the germ of ϱ_f spans the line. By (ii), $\mathfrak{D}_{\mathbf{p}}\nu_f^{\mathbb{T}} = 0$; near $f^\star$, $\nu_f^{\mathbb{T}} = \varrho_f^{\mathbb{T}}\mathbf{1}_{(f^\star, f^\star+\delta)}dt$, integrable by (iii), so its germ extends by zero on the torus's side. (iii) gives the common germ. □

50.40 Chapter 41: reading a ray

In this section $f^\star = f(\alpha^\star)$, and the symbol χ and the second symbol χ_1 of polynomials $p_0, \dots, p_h$ are those of Definition 40.4. One lemma carries the proofs of the selection: the solutions of a recurrence whose symbol has distinct roots, sorted by their growth.

Lemma S26. *Let $p_0, \dots, p_h \in \mathbb{C}[k]$, $h \geq 1$, have $\deg p_0 = \deg p_h = D \geq \deg p_i$ for every i, let χ have distinct roots $\lambda_1, \dots, \lambda_h$, and let k_1 be an integer with $p_0(k)p_h(k) \neq 0$ for every integer $k \geq k_1$. Let $\mathcal{V}$ be the space of the sequences $(x(k))_{k\geq k_1}$ with $\sum_i p_i(k)x(k+i) = 0$ for every integer $k \geq k_1$.*

(i) $\dim\mathcal{V} = h$, and $\mathcal{V}$ has a basis $x_1, \dots, x_h$ with $x_c(k) = \lambda_c^k k^{\rho_c}\big(1 + O(1/k)\big)$ as $k \to \infty$, $\rho_c = -\chi_1(\lambda_c)/(\lambda_c\chi'(\lambda_c))$.

(ii) For $R \geq 0$, the $x \in \mathcal{V}$ with $x(k) = O(r^k)$ for every $r > R$ are the combinations of the x_c with $|\lambda_c| \leq R$, and those with $x(k) = O(r^k)$ for some $r < R$ are the combinations of the x_c with $|\lambda_c| < R$.

Proof. (i) The map $x \mapsto (x(k_1), \dots, x(k_1 + h - 1))$ is a bijection of $\mathcal{V}$ onto $\mathbb{C}^h$, the recurrence at k giving $x(k + h)$ from the h values before it, $p_h(k) \neq 0$; so $\dim\mathcal{V} = h$. The leading coefficients $c_i = [k^D]p_i$ have $c_0c_h \neq 0$, so $\chi(0) \neq 0$ and the roots are nonzero. If $D = 0$ the recurrence has

constant coefficients, $\rho_c = 0$, and $x_c(k) = \lambda_c^k$. Let $D \ge 1$. Divided by k^D the recurrence has the coefficients $p_i(k)/k^D$, holomorphic at $k = \infty$ with the values c_i there; written as a system for $(x(k), \dots, x(k+h-1))$, its matrix at $k = \infty$ is the companion matrix of χ/c_h, whose eigenvalues are the λ_c. This is the normal case of Birkhoff's theorem on linear difference equations, which applies because the coefficients are holomorphic at infinity and the eigenvalues of the matrix there are distinct and nonzero: for every c there is a solution, defined at all large integers, with an asymptotic expansion $\lambda_c^k k^\rho\big(1 + \sum_{m\ge1} e_m k^{-m}\big)$ as $k \to \infty$ that is a formal solution of the recurrence. Divided by λ_c^k it is a formal solution of $\sum_i p_i(k)\lambda_c^i \varsigma^i$, so $\rho = \rho_c$ by Lemma S24, λ_c being a simple root. Solving the recurrence for $x(k)$ downward, $p_0(k) \ne 0$, extends each of these solutions to $k \ge k_1$; call them x_c.

(ii) and the independence. Let $x = \sum_c a_c x_c$ with not all a_c zero, $R_x = \max\{|\lambda_c| : a_c \ne 0\}$, $\sigma = \max\{\operatorname{Re}\rho_c : a_c \ne 0,\ |\lambda_c| = R_x\}$, and C_0 the set of the c with $a_c \ne 0$, $|\lambda_c| = R_x$ and $\operatorname{Re}\rho_c = \sigma$. Then

$$\frac{x(k)}{R_x^k k^\sigma} = \sum_{c\in C_0} a_c\Big(\frac{\lambda_c}{R_x}\Big)^k k^{i\operatorname{Im}\rho_c} + o(1),$$

the other terms being $O\big((|\lambda_c|/R_x)^k k^{\operatorname{Re}\rho_c-\sigma}\big)$ with $|\lambda_c| < R_x$, or $O(k^{\operatorname{Re}\rho_c-\sigma})$ with $\operatorname{Re}\rho_c < \sigma$, and the remainders $O(1/k)$. The pairs $(\lambda_c/R_x, \operatorname{Im}\rho_c)$, $c \in C_0$, are distinct, the λ_c being distinct, so by Lemma S23(i) the right side does not tend to 0, and $|x(k)| \ge \eta R_x^k k^\sigma$ for some $\eta > 0$ and infinitely many k. So $x \ne 0$, and the x_c are independent, a basis by (i). And $x(k) = O(r^k)$ fails for every $r < R_x$. If $x(k) = O(r^k)$ for every $r > R$, then $R_x \le R$; if for some $r < R$, then $R_x < R$. Conversely $x_c(k) = O(r^k)$ for every $r > |\lambda_c|$. □

Proposition 41.1 (The low-end relations at every pole). *As stated.*

Proof. By Proposition 40.5 the identity $\sum_{i=0}^h p_i(k)\langle1\rangle_{k+i} = 0$ holds as one of meromorphic functions of k. For $i > j$ the value $\langle1\rangle_{k+i}$ is holomorphic at $k = -j$, $k+i$ being near the positive integer $i-j$, where it converges absolutely (Lemma S20(iv), the origin being 0). So $S(k) = \sum_{i\le\min(h,j)} p_i(k)\langle1\rangle_{k+i} = -\sum_{i=j+1}^h p_i(k)\langle1\rangle_{k+i}$ is holomorphic at $-j$ with the value of (i). For $i \le j$, Proposition 39.35(ii) at the integer $j-i$ gives $(k+j)^{n-1}\langle1\rangle_{k+i} \to V_1\,\mathrm{CT}(f^{i-j})$ as $k \to -j$, and $p_i(k) = (k+j)^{m_0}\big([(k+j)^{m_0}]p_i + O(k+j)\big)$. So

$$(k+j)^{n-1-m_0}S(k) = \sum_{i\le\min(h,j)} \frac{p_i(k)}{(k+j)^{m_0}}\,(k+j)^{n-1}\langle1\rangle_{k+i} \;\longrightarrow\; V_1 \sum_{i\le\min(h,j)} [(k+j)^{m_0}]p_i\cdot\mathrm{CT}\left(f^{i-j}\right)$$

as $k \to -j$. For $m_0 < n-1$ the left side tends to 0, S being holomorphic at $-j$, and $V_1 > 0$ gives (ii). For $m_0 = n-1$ the left side tends to $S(-j)$, which (i) gives, and this is (iii). The reciprocal stride $f^{-1} = \alpha^{-\mathbf{m}_1}\prod_l K_l^{s_{1l}}\Psi_l^{t_{1l}}$ is a Laurent polynomial whose coefficients are polynomials with integer coefficients in the weights, so every $\mathrm{CT}(f^{i-j})$ lies in the field of the weights. □

Proposition 41.2 (The values live on the slit plane). *As stated.*

Proof. (i) By Proposition 40.2(i), μ_f is carried by $(0, f^\star]$ and $\langle1\rangle_k = \int t^k\mu_f(dt)$. For $|q| < 1/f^\star$, $\sum_{k\ge k_0}|q|^{k-k_0}\int t^k\mu_f(dt) = \int t^{k_0}\mu_f(dt)/(1-|q|t) \le \langle1\rangle_{k_0}/(1-|q|f^\star)$, so Fubini's theorem exchanges the sum and the integral and gives the formula. For q in a compact set $Q \subseteq \mathbb{C}\setminus[1/f^\star,\infty)$ the function $(q,t)\mapsto|1-qt|$ is continuous and positive on $Q\times[0,f^\star]$, since $qt = 1$ with $t \in (0,f^\star]$ means $q = 1/t \in [1/f^\star,\infty)$; so it is at least some $\delta_Q > 0$ there, the integrand is holomorphic in q and at most t^{k_0}/δ_Q, which is μ_f-integrable, and the integral is holomorphic on $\mathbb{C}\setminus[1/f^\star,\infty)$ (dominated convergence and Morera's theorem).

(ii) Put $t_0 = 1/x \in (0, f^\star)$. By Proposition 40.3(i), ϱ_f is real-analytic on $(0, f^\star)$, so there is $\delta > 0$ with $[t_0 - 2\delta, t_0 + 2\delta] \subseteq (0, f^\star)$ such that $\phi(t) = t^{k_0}\varrho_f(t)$ extends holomorphically to the disc $|t - t_0| \le 2\delta$. Write $G = G_1 + G_2$, with $G_1(q) = \int_{|t-t_0|\ge\delta} t^{k_0}\mu_f(dt)/(1-qt)$ and $G_2(q) = \int_{t_0-\delta}^{t_0+\delta} \phi(t)\,dt/(1-qt)$. For q close enough to x, $1/q$ lies within $\delta/2$ of t_0, so $1 - qt$ does not vanish on the support of the first integral, and G_1 is holomorphic near x as in (i). Let Γ_+ and Γ_- be the half circles $t_0 + \delta e^{i\vartheta}$ from $t_0 - \delta$ to $t_0 + \delta$ through the upper and through the lower half plane. For q near x with $\operatorname{Im} q > 0$ the pole $t = 1/q$ of the integrand lies in the disc and below the real axis, $\operatorname{Im}(1/q) = -\operatorname{Im} q/|q|^2$, so Cauchy's theorem moves the segment of G_2 onto Γ_+: $G_2(q) = \int_{\Gamma_+} \phi(t)\,dt/(1-qt)$, and the right side is holomorphic in q on the whole neighbourhood of x where $1/q$ stays within $\delta/2$ of t_0. So G continues from the upper half plane across a neighbourhood of x, with $G(x + i0) = G_1(x) + \int_{\Gamma_+} \phi(t)\,dt/(1-xt)$; likewise from below with Γ_-. The difference is the integral of $\phi(t)/(1-xt)$ along Γ_+ followed by Γ_- reversed, a clockwise circle around t_0, inside which the integrand has one simple pole, at $t_0 = 1/x$, with the residue $-\phi(1/x)/x$, as $1 - xt = -x(t - 1/x)$. So $G(x + i0) - G(x - i0) = -2\pi i \cdot \big(-\phi(1/x)/x\big) = 2\pi i\, x^{-1-k_0}\varrho_f(1/x)$.

(iii) On $\mathbb{T}$, $f = \prod_j |K_j(\alpha)|^{-2\sigma_j} \ge f^\star$ (proof of Definition 40.11), finite at the points of X_F; so the native value of a native gauge on $\mathbb{T}$ lies in $[f^\star, \infty)$.

(iv) By Proposition 38.10 every conjugate of $f^\star$ over the field $\Bbbk$ of the weights is the native value of a nondegenerate native gauge. Let $\sum_i p_i(k)\langle 1\rangle_{k+i} = 0$ for all large integers k, with $p_i \in \Bbbk[k]$ not all zero, of largest degree D. By Proposition 38.9, $\langle 1\rangle_k > 0$ for large k and $\langle 1\rangle_{k+i}/\langle 1\rangle_k \to (f^\star)^i$; dividing the recurrence by $k^D\langle 1\rangle_k$ and letting $k \to \infty$ gives $\sum_i [k^D]p_i \cdot (f^\star)^i = \chi(f^\star) = 0$. The symbol is a nonzero polynomial over $\Bbbk$, so the minimal polynomial of $f^\star$ over $\Bbbk$ divides it, and every conjugate of $f^\star$ is a root. A real conjugate in $(0, f^\star)$ lies on the slit by its definition. □

Theorem 41.3 (Positive selection). *As stated.*

Proof. As in the proof of Proposition 41.2(iv), $\chi(f^\star) = 0$; the hypotheses on the degrees make χ of degree h with $\chi(0) = [k^D]p_0 \ne 0$. The walls $\kappa_{0,S} + k\kappa_{1,S}$ increase with k, so the values converge at every integer $k \ge k_1$, and by Proposition 40.5 the recurrence holds there: the values are a solution. Lemma S26(i) gives $\dim \mathcal{V} = h$ and a basis $x_1, \dots, x_h$.

(i) For each i, with $m = k + i$,

$$\begin{aligned}\sum_{k\ge k_1} p_i(k)x(k+i)\,q^{k-k_1+h} &= q^{h-i}\sum_{m\ge k_1+i} p_i(m-i)x(m)\,q^{m-k_1}\\ &= q^{h-i}p_i\Big(q\frac{d}{dq} + k_1 - i\Big)\Big(X - \sum_{m=k_1}^{k_1+i-1} x(m)\,q^{m-k_1}\Big),\end{aligned}$$

since $q\frac{d}{dq}$ multiplies q^{m-k_1} by $m - k_1$. Summed over i the left sides vanish, so $L_qX = R_x$ with

$$R_x = \sum_{i=0}^{h}\sum_{m=k_1}^{k_1+i-1} p_i(m-i)\,x(m)\,q^{h-i+m-k_1},$$

a polynomial of degree at most $h - 1$, linear in $x(k_1), \dots, x(k_1 + h - 1)$. With $c_i = [k^D]p_i$, $p_i(q\frac{d}{dq} + c) = c_i(q\frac{d}{dq})^D + \cdots$ and $(q\frac{d}{dq})^D = q^D\frac{d^D}{dq^D} + \cdots$, the dots of lower order in $\frac{d}{dq}$; so the coefficient of $\frac{d^D}{dq^D}$ in L_q is $\sum_i q^{h-i}c_iq^D = q^{D+h}\chi(1/q)$, which vanishes in $\mathbb{C}^\times$ exactly at the $1/\lambda_c$. For the values, X is the generating function of Proposition 41.2(i) with $k_0 = k_1$.

(ii) For $k \ge k_1$, $\langle 1\rangle_k = \int t^k \mu_f(dt) \le (f^\star)^{k-k_1}\langle 1\rangle_{k_1}$, μ_f being carried by $(0, f^\star]$ (Proposition 40.2(i)); so the values lie in the subspace of the statement, which Lemma S26(ii) at $R = f^\star$ identifies. By Proposition 40.3(ii), with $a = \frac{n-3}{2}$ and a small $\delta > 0$,

$$\langle 1\rangle_k = \int_0^\delta (f^\star - s)^k\, s^a g(s)\, ds + O\big((f^\star - \delta)^{k-k_1}\langle 1\rangle_{k_1}\big).$$

In $\sigma = -\log(1 - s/f^\star)$ the integral is $(f^\star)^k \int_0^{\sigma_\delta} e^{-k\sigma} h(\sigma)\, d\sigma$ with $h(\sigma) = s^a g(s)\, f^\star e^{-\sigma} = g(0)(f^\star)^{a+1}\sigma^a\big(1 + O(\sigma)\big)$, and Watson's lemma, which applies because $h(\sigma)\sigma^{-a}$ is continuous at 0 and $a > -1$, gives $\langle 1\rangle_k = C(f^\star)^k k^{-\frac{n-1}{2}}(1 + o(1))$ with $C = g(0)\Gamma(\frac{n-1}{2})(f^\star)^{\frac{n-1}{2}} > 0$. Last, $f^\star$ is a simple root of χ and the recurrence meets the conditions of Proposition 40.5, so Theorem 40.6(iii) gives $\frac{n-3}{2} = -1 + \chi_1(f^\star)/(f^\star\chi'(f^\star))$.

(iii) By Lemma S26(ii) at $R = \lambda'$, the solutions with $x(k) = O(r^k)$ for some $r < \lambda'$ are the multiples of x_1, $\lambda_1 = f^\star$ being the only root of modulus less than λ'; the values are such a solution, $f^\star < \lambda'$, and they are not 0, so they span that line. A generating function converges on $|q| < 1/f^\star$ exactly when $\limsup |x(k)|^{1/k} \le f^\star$, that is when $x(k) = O(r^k)$ for every $r > f^\star$, and Lemma S26(ii) at $R = f^\star$ gives the same line. For the origin 0, Proposition 40.5 gives the low-end relation $a\mathsf{L}_0 + \sum_{i\ge1} p_i(0)\langle 1\rangle_i = 0$ with $\mathsf{L}_0 = V_1$ (Definition 39.37), that is $\ell(\langle 1\rangle) = V_1$; a nonzero solution of least growth is $x = c\langle 1\rangle$ with $c \ne 0$, and $\ell(x) = cV_1$.

(iv) ℓ is a linear form on $\mathcal{V}$ with $\ell(\langle 1\rangle) = V_1 \ne 0$, so $\{\ell = 0\}$ is a hyperplane that does not contain $\langle 1\rangle$, and $\langle 1\rangle - x^{(0)} \in \{\ell = 0\}$ gives M. Take $x_1 = \langle 1\rangle$, which (iii) allows. The $z_c = x_c - \frac{\ell(x_c)}{V_1}x_1$, $2 \le c \le h$, form a basis of $\{\ell = 0\}$, and $x^{(i)} = \sum_c S_{ic} z_c$ with S invertible. The equations of the statement read $\mathbf{X}_K M^{(K)} = -\big(x^{(0)}(K + l)\big)_l$ with $\mathbf{X}_K = \big[x^{(i)}(K + l)\big]_{l,i}$, while $\mathbf{X}_K M = \big(\langle 1\rangle_{K+l} - x^{(0)}(K + l)\big)_l$; so, when $\mathbf{X}_K$ is invertible, $M^{(K)} - M = -\mathbf{X}_K^{-1} v_K$ with $v_K = (\langle 1\rangle_{K+l})_l$. Now $\mathbf{X}_K = \mathbf{Z}_K S^{\mathsf{T}}$ with $\mathbf{Z}_K = [z_c(K + l)]_{l,c}$, and $z_c(K + l) = \lambda_c^K K^{\rho_c}\big(\lambda_c^l + o(1)\big)$, since $x_c(K + l) = \lambda_c^{K+l}(K + l)^{\rho_c}\big(1 + O(1/K)\big)$ and $x_1(K + l) = O\big((f^\star)^K\big)$ with $f^\star < |\lambda_c|$. So $\mathbf{Z}_K = \mathbf{N}_K\Lambda_K$ with $\Lambda_K = \operatorname{diag}(\lambda_c^K K^{\rho_c})_{c\ge2}$ and $\mathbf{N}_K \to [\lambda_c^l]_{0\le l\le h-2,\ 2\le c\le h}$, the Vandermonde matrix of the distinct $\lambda_2, \dots, \lambda_h$, which is invertible. For large K, $\mathbf{X}_K$ is invertible, $M^{(K)}$ is unique, and with $|v_K| = O\big((f^\star)^K K^{-\frac{n-1}{2}}\big)$ by (ii),

$$\begin{aligned} |M^{(K)} - M| &\le \big\|(S^{\mathsf{T}})^{-1}\big\|\, \big\|\Lambda_K^{-1}\big\|\, \big\|\mathbf{N}_K^{-1}\big\|\, |v_K| \\ &= O\Big(\max_{c\ge2} |\lambda_c|^{-K} K^{-\operatorname{Re}\rho_c}\,(f^\star)^K K^{-\frac{n-1}{2}}\Big) = O\big((f^\star/\lambda')^K K^{C'}\big). \end{aligned}$$

Over $\Bbbk$: the recurrence solved forward from initial values in $\Bbbk$, $p_h(k) \ne 0$, gives solutions with values in $\Bbbk$, and $\mathcal{V}$ has a basis of them; ℓ has its coefficients in $\Bbbk$ and $V_1 \in \Bbbk$, so $x^{(0)}$ and a basis of $\{\ell = 0\}$ can be taken with values in $\Bbbk$, and the equations for $M^{(K)}$ then have their coefficients in $\Bbbk$. □

Proposition 41.4 (Positivity is the moment problem of the stride's law). *As stated.*

Proof. (i) Every $\langle 1\rangle_{K+m}$, $m \in \mathbb{N}$, converges with $\langle 1\rangle_K$, μ_f being carried by $(0, f^\star]$, and $L_{K,p}(\langle 1\rangle) = \sum_m p_m \int t^{K+m}\mu_f(dt) = \int t^K p\, d\mu_f$ (Proposition 40.2(i)). The integrand is nonnegative, and positive off the finitely many zeros of p on $(0, f^\star)$, where μ_f has a positive density (Proposition 40.3(i)); so the integral is positive.

(ii) By the Markov–Lukács theorem on polynomials nonnegative on an interval, which applies to $[0, f^\star]$, a real polynomial of degree $2m$ nonnegative there is $A^2 + t(f^\star - t)B^2$ with real A and B of degrees at most m and $m - 1$, and one of degree $2m + 1$ is $tA^2 + (f^\star - t)B^2$ with real A and

B of degrees at most m; every term has degree at most that of the polynomial. For $q = \sum_i q_i t^i$, $L_{K,q^2}(x) = \sum_{i,i'} q_i q_{i'}\, x(K+i+i')$, and likewise L_{K,tq^2}, $L_{K,(f^\star-t)q^2}$ and $L_{K,t(f^\star-t)q^2}$ are the quadratic forms of the other three Hankel matrices. The four kinds have degree at most N exactly when $\deg q$ is at most $\lfloor \frac{N}{2} \rfloor$, $\lfloor \frac{N-1}{2} \rfloor$, $\lfloor \frac{N-1}{2} \rfloor$ and $\lfloor \frac{N-2}{2} \rfloor$, which gives the sizes. If $L_{K,p}(x) \ge 0$ for every $p \ge 0$ on $[0, f^\star]$ of degree at most N, the four quadratic forms are nonnegative, these p being among them; conversely, if the forms are nonnegative, $L_{K,p}(x) \ge 0$ for every p of the four kinds, and by linearity for every sum of them.

(iii) If $x(K+m) = \int t^m \nu(dt)$ for a positive ν on $[0, f^\star]$, then $L_{K,p}(x) = \int p\, d\nu \ge 0$. Conversely, the linear functional $\Lambda(p) = L_{K,p}(x)$ on real polynomials is nonnegative on those nonnegative on $[0, f^\star]$, so $|\Lambda(p)| \le \Lambda(1) \max_{[0,f^\star]} |p|$, the polynomials $\max |p| \pm p$ being nonnegative there. Polynomials are dense in $C([0, f^\star])$ (the Weierstrass approximation theorem), so Λ extends continuously to $C([0, f^\star])$, and the extension is positive: a continuous $\varphi \ge 0$ is the uniform limit of polynomials p_l, and $p_l + \max |\varphi - p_l| \ge 0$. The Riesz representation theorem gives a positive measure ν on $[0, f^\star]$ with $\Lambda(\varphi) = \int \varphi\, d\nu$, and at $\varphi = t^m$ this is $x(K+m) = \int t^m \nu(dt)$. Two finite measures on $[0, f^\star]$ with the same moments agree on polynomials, hence on $C([0, f^\star])$, hence are equal. For the values, $t^K \mu_f$ is a finite positive measure on $(0, f^\star]$ with the moments $\langle 1 \rangle_{K+m}$. □

Theorem 41.5 (The rate of positivity off the segment). *As stated.*

Proof. Put $A(p) = L_{K,p}(\langle 1 \rangle) = \int t^K p\, d\mu_f$ and $B(p) = L_{K,p}(u) = \int_{I_\lambda} t^K p(t) \nu(t)\, dt$, both convergent, $|t|^{K+m} \le C_m |t|^K$ on the bounded I_λ. For $p \ge 0$ on $[0, f^\star]$, $A(p) \ge 0$ (Proposition 41.4(i)), and $A(p) + \varepsilon B(p) \ge 0$ holds for every ε when $B(p) = 0$ and otherwise on a closed half line that contains 0. So E_N, the intersection over the p of degree at most N, is a closed interval that contains 0, and if p_1, p_2 of degree at most N have $B(p_1)$ and $B(p_2)$ of opposite signs, its length is at most $A(p_1)/|B(p_1)| + A(p_2)/|B(p_2)|$.

Let $w(t) = 2t/f^\star - 1$, which maps $[0, f^\star]$ onto $[-1, 1]$, and T_m the polynomial of degree m with $T_m(\cos \vartheta) = \cos m\vartheta$; then $|T_m(w)| \le 1$ for $|w| \le 1$ and $|T_m(w)| = \cosh\big(m \operatorname{arccosh} |w|\big)$ for $|w| \ge 1$. On the part of I_λ off $[0, f^\star]$ put $\Gamma(t) = \operatorname{arccosh} |w(t)|$: it is C^1, it grows as t moves from the segment toward λ, $|w(t)|$ doing so, and $\Gamma(\lambda) = \log\big(|w| + \sqrt{w^2-1}\big) = g(\lambda)$ at $w = w(\lambda)$, the branch of the statement; $g(\lambda) > 0$ as $|w(\lambda)| > 1$. Let $\eta(t) = f^\star - t$ if $\lambda > f^\star$ and $\eta(t) = t$ if $\lambda < 0$, so that $\eta \ge 0$ on $[0, f^\star]$ and $\eta(\lambda) < 0$, and take $p_1 = T_m(w)^2$ and $p_2 = \eta\, T_m(w)^2$, nonnegative on $[0, f^\star]$, of degrees $2m$ and $2m+1$. Then $A(p_1) \le \langle 1 \rangle_K$ and $A(p_2) \le f^\star \langle 1 \rangle_K$.

Fix $\delta > 0$ so small that $I' = \{t \in I_\lambda : \ |t - \lambda| \le \delta\}$ lies off $[0, f^\star]$ and on I': t^K and η have the signs of their values at λ, $|t^K| \ge \frac{1}{2}|\lambda|^K$, $|\eta(t)| \ge \frac{1}{2}|\eta(\lambda)|$, $\nu(t) = c|\lambda - t|^a(1 + \epsilon(t))$ with $|\epsilon| \le \frac{1}{2}$, and $\Gamma(t) \ge g(\lambda) - \Gamma_1 |\lambda - t|$ for a constant Γ_1. On I' the integrand of $B(p_i)$ has the constant sign of $c\lambda^K \eta(\lambda)^{i-1}$, and by $\cosh^2 \ge \frac{1}{4} e^{2m\Gamma}$ its modulus is at least $c_1 e^{2mg(\lambda)} e^{-2m\Gamma_1 |\lambda - t|} |\lambda - t|^a$ for a constant $c_1 > 0$; so its integral over I' has modulus at least

$$c_1 e^{2mg(\lambda)} \int_0^\delta e^{-2m\Gamma_1 s} s^a\, ds = c_1 e^{2mg(\lambda)} (2m\Gamma_1)^{-a-1} \big(\Gamma(a+1) + o(1)\big) \ge c_2\, m^{-a-1} e^{2mg(\lambda)}$$

for large m. Off I', $T_m(w)^2 \le \cosh^2\big(m\Gamma(\lambda_\delta)\big) \le e^{2m(g(\lambda) - \eta')}$, with λ_δ the end of I' other than λ and $\eta' = g(\lambda) - \Gamma(\lambda_\delta) > 0$, by the monotonicity of Γ and $|T_m| \le 1$ on $[0, f^\star]$; $\int_{I_\lambda} |t|^K |\nu|\, dt$ being finite and η bounded on I_λ, that part of $B(p_i)$ is at most $C_3 e^{2m(g(\lambda) - \eta')}$ in modulus. So for large m, $B(p_1)$ and $B(p_2)$ have the opposite signs of $c\lambda^K$ and $-c\lambda^K$, and moduli at least $\frac{c_2}{2} m^{-a-1} e^{2mg(\lambda)}$. With $m = \lfloor N/2 \rfloor$ for p_1 and $m = \lfloor (N-1)/2 \rfloor$ for p_2, so that $2m \ge N - 2$, the length of E_N is at most $C\, N^{a+1} e^{-Ng(\lambda)}$ for large N.

For $\lambda > f^\star$, $\rho = f^\star/\lambda \in (0,1)$, $w = \frac{2}{\rho} - 1 > 1$, $w^2 - 1 = 4(1-\rho)/\rho^2$ and $w + \sqrt{w^2-1} = \big(2-\rho+2\sqrt{1-\rho}\big)/\rho = \big(1+\sqrt{1-\rho}\big)^2/\rho$. So $e^{-g(\lambda)} = \rho/(1+\sqrt{1-\rho})^2 = (1-\sqrt{1-\rho})/(1+\sqrt{1-\rho})$, using $\rho = (1-\sqrt{1-\rho})(1+\sqrt{1-\rho})$, and $\sqrt{1-\rho} = 1 - \frac{\rho}{2} + O(\rho^2)$ gives $\frac{\rho}{4} + O(\rho^2)$. □

Proposition 41.6 (What positivity cannot see). *As stated.*

Proof. (i) $\mu_f + \varepsilon\nu \geq \mu_f - |\varepsilon|\,|\nu| \geq (1 - |\varepsilon|C)\mu_f \geq 0$. For real $k \geq K$, $t^k \leq (f^\star)^{k-K} t^K$ on $(0, f^\star]$, so $\int t^k\, d|\nu| \leq C(f^\star)^{k-K}\langle 1\rangle_K$, and $\langle 1\rangle_k + \varepsilon u(k) = \int t^k\, d(\mu_f + \varepsilon\nu)$ (Proposition 40.2(i)). For $K' \geq K$ and $p \geq 0$ on $[0, f^\star]$, $L_{K',p}(\langle 1\rangle + \varepsilon u) = \int t^{K'} p\, d(\mu_f + \varepsilon\nu) \geq 0$.

(ii) $t^K(\mu_f + \varepsilon\nu)$ is a finite measure on $[0, f^\star]$, of total variation at most $(1 + |\varepsilon|C)\langle 1\rangle_K$, with the stated moments; two finite signed measures on $[0, f^\star]$ with the same moments agree on polynomials, hence on $C([0, f^\star])$ by the Weierstrass approximation theorem, hence are equal. On J its density is $t^K(\varrho_f + \varepsilon\nu')$, ν' the density of ν. If it agreed almost everywhere on $(0, f^\star)$ with a real-analytic function φ, then on J, $\nu' = (t^{-K}\varphi - \varrho_f)/\varepsilon$ almost everywhere, a real-analytic function on J, ϱ_f being real-analytic on $(0, f^\star)$ (Proposition 40.3(i)); this is excluded. $t^K\mu_f$ has the real-analytic density $t^K\varrho_f$.

(iii) Let $|\nu'| \leq B$ on $(0, \delta]$. For $K_0 > -1$, $\int t^{K_0} d|\nu| \leq B\int_0^\delta t^{K_0} dt + \max_{[\delta, f^\star]} t^{K_0} \cdot C\mu_f([\delta, f^\star]) < \infty$ (Proposition 40.2(i)), so $u(k)$ converges for $\operatorname{Re} k \geq K_0$. Lemma S21(ii), with the measure ν on $(0, f^\star]$, the operator $\mathfrak{D}_{\mathbf{p}}$, for which $\mathfrak{D}_{\mathbf{p}}^\dagger t^k = \sum_i p_i(k) t^{k+i}$, and $E = \mathfrak{D}_{\mathbf{p}}\nu = 0$, gives $\sum_i p_i(k) u(k+i) = 0$ for $\operatorname{Re} k \geq K_0$, for every $K_0 > -1$. At $k = 0$, $p_0(0) = 0$, p_0 vanishing to order at least $n - 1 \geq 1$ at 0 (Proposition 40.5), and what remains is $\sum_{i \geq 1} p_i(0) u(i) = 0$. □

Proposition 41.7 (A recurrence of order two is the volume of the direction times a continued fraction). *As stated.*

Proof. (i) $\langle 1\rangle_{k+1} = \int t^{k+1}\mu_f(dt) < f^\star \int t^k \mu_f(dt)$, μ_f having a positive density on $(0, f^\star)$ and no mass at $f^\star$, whose preimage is the point $\log \alpha^\star$ (Proposition 40.3(i)); and $\langle 1\rangle_k > 0$. By Proposition 40.5 the recurrence holds at every integer $k \geq 1$, the origin being 0; divided by $\langle 1\rangle_{k+1}$ it reads $p_0(k)/\rho_k + p_1(k) + p_2(k)\rho_{k+1} = 0$.

(ii) The low-end relation (Proposition 40.5, Definition 39.37) is $aV_1 + p_1(0)\langle 1\rangle_1 + p_2(0)\langle 1\rangle_2 = 0$, and $\langle 1\rangle_2 = \rho_1\langle 1\rangle_1$. Let $\varphi(\rho) = -a/(p_1(0) + p_2(0)\rho)$. If $\varphi(0)$ and $\varphi(f^\star)$ are finite and positive, the affine denominator has the sign of $-a$ at both ends of $[0, f^\star]$, so it does not vanish there, $a \neq 0$, and φ is continuous and monotone on $[0, f^\star]$, strictly unless $p_2(0) = 0$, when the two values agree. As $\rho_1 \in (0, f^\star)$, $\langle 1\rangle_1/V_1 = \varphi(\rho_1)$ lies between $\varphi(0)$ and $\varphi(f^\star)$, strictly when they differ.

(iii) The symbol $\chi(\lambda) = c_0 + c_1\lambda + c_2\lambda^2$ has real coefficients and the real root $f^\star$, so λ_2 is real, with $|\lambda_2| = \lambda' > f^\star$. By Lemma S26(i) and the proof of Theorem 41.3(iii), $\mathcal{V}$ has the basis $\langle 1\rangle$, x_2, with $x_2(k) = \lambda_2^k k^{\rho_2}(1 + O(1/k))$. For $r \in [0, f^\star]$ and $K \geq 1$ put

$$\psi = \langle 1\rangle_{K+2} - r\langle 1\rangle_{K+1}, \qquad \phi = x_2(K+2) - r\,x_2(K+1), \qquad y = \phi\,\langle 1\rangle - \psi\,x_2,$$

a solution with $y(K+2) = r\,y(K+1)$. Let $\tau_k = x_2(k+1)/x_2(k)$, defined for $k \geq J$ and tending to λ_2, and $\rho_k \to f^\star$ (Proposition 38.9). Then $\phi = x_2(K+1)(\tau_{K+1} - r)$ with $|\tau_{K+1} - r| \geq \frac{1}{2}(\lambda' - f^\star)$ for large K, so $|\phi| \geq c\,(\lambda')^K K^{\rho_2}$, and $|\psi| \leq 2f^\star\langle 1\rangle_{K+1} = O\big((f^\star)^K K^{-\frac{n-1}{2}}\big)$ by Theorem 41.3(ii), uniformly in r. So $|\psi/\phi| \leq C_1(f^\star/\lambda')^K K^{C'}$. Write $y(k) = \phi\,\langle 1\rangle_k\big(1 - \epsilon_k\big)$ with $\epsilon_k = \frac{\psi}{\phi}\frac{x_2(k)}{\langle 1\rangle_k}$. For $k < J$, $|\epsilon_k| \leq C_J|\psi/\phi| \to 0$. For $J \leq k \leq K+1$,

$$\epsilon_k = \frac{\rho_{K+1} - r}{\tau_{K+1} - r}\prod_{l=k}^{K}\frac{\rho_l}{\tau_l},$$

and choosing J larger if needed, $|\rho_l/\tau_l| \le \bar q = \frac12(1+f^\star/\lambda') < 1$ for $l \ge J$, while $|(\rho_{K+1}-r)/(\tau_{K+1}-r)| \to (f^\star-r)/|\lambda_2-r| \le (f^\star-r)/(\lambda'-r) \le f^\star/\lambda' < \bar q$ uniformly in $r \in [0, f^\star]$. So there is K_0 such that for $K \ge K_0$ and every r, $|\epsilon_k| < 1$ for $1 \le k \le K+1$, hence $y(k) \ne 0$ there. For such K put $\sigma_k = y(k+1)/y(k)$, $1 \le k \le K+1$; $\sigma_{K+1} = r$, and the recurrence at k, divided by $y(k+1)$, gives $p_1(k) + p_2(k)\sigma_{k+1} = -p_0(k)/\sigma_k \ne 0$, so $\sigma_k = \mathsf{M}_k(\sigma_{k+1})$ for $1 \le k \le K$. So $\mathsf{M}_1 \circ \cdots \circ \mathsf{M}_K(r) = \sigma_1$ is defined, and

$$\sigma_1 = \frac{\langle 1\rangle_2 - (\psi/\phi)x_2(2)}{\langle 1\rangle_1 - (\psi/\phi)x_2(1)} = \rho_1 + O\big((f^\star/\lambda')^K K^{C'}\big),$$

uniformly in r. By (ii) and $a \ne 0$, $p_1(0) + p_2(0)\rho_1 \ne 0$ and $\langle 1\rangle_1 = -aV_1/(p_1(0) + p_2(0)\rho_1)$. Let Σ_K be the set of the $\mathsf{M}_1 \circ \cdots \circ \mathsf{M}_K(r)$ over the $r \in (0, f^\star)$ whose intermediate values lie in $(0, f^\star)$. An element of Σ_{K+1}, built from r, is $\mathsf{M}_1 \circ \cdots \circ \mathsf{M}_K(r')$ with $r' = \mathsf{M}_{K+1}(r) \in (0, f^\star)$ and the same intermediate values, so it lies in Σ_K; and $\rho_1 \in \Sigma_K$, built from $r = \rho_{K+1}$, its intermediate values being the $\rho_k \in (0, f^\star)$ by (i). □

Definition 41.8 (The procedure that reads a ray from its list). As stated.

Proof. (1) V_1 is the coefficient of Proposition 39.34; the maps of Proposition 39.11(ii) that are symmetries generate a group of symmetries, and a finite one is chosen. (2) The search stops by Theorem 39.22, every box of it being finite (Proposition 39.16(iv)); Proposition 41.10(iii) and (v) bound the strengths and primes at which an elimination misjudges acceptance. (3) The reductions from the relations the targets need are those of the box by Proposition 41.10(vi); the evaluations give the values of the entries of $\mathbf{B}$ at the strengths where the elimination has the generic pivots (Proposition 41.10(i)), the reconstruction is Proposition 41.10(ii), the check is Proposition 41.10(iv) and (v), and the certificate and the one-step relation are Theorem 39.21(ii) and (iii). (4) By Theorem 39.21(iv) Proposition 39.6 applies to the spanning set and its matrix: the first dependence $\sum_i q_i w_i = 0$ gives $\sum_j p_j(k) f^j \in \mathcal{L}$ (Proposition 39.6(ii)), and the ratios q_i/q_h are ratios of signed maximal minors (Proposition 39.6(iii)), rational functions whose values at a point k_0 where $\mathbf{B}(k_0-h+1), \dots, \mathbf{B}(k_0)$ are finite and $w_0(k_0), \dots, w_{h-1}(k_0)$ independent are the coefficients of the dependence of the rows at k_0, so Proposition 41.10(ii) reconstructs them. The relation is the law of [1] when the spanning set is independent (Theorem 39.21(iv)), as under Proposition 39.42(i). The zeros of $p_0(k) = q_h(k+h)$ are those described, by the divisibility of Proposition 39.6(iii). (5) is Definition 40.10, which applies by Proposition 40.5, or Theorem 41.3(iv) with Proposition 41.4. (6) The closings are a solution with values in germs at $-\infty$ (Theorem 39.33), so Theorem 39.21(iii) gives $\varsigma^{-1}v = \mathbf{B}v$ for their vector $v(k) = \mathsf{C}_{-k}(\mathbf{b})$, that is $\mathsf{C}_{j+1}(\mathbf{b}) = \mathbf{B}(-j)\mathsf{C}_j(\mathbf{b})$ for all large j; the reflected recurrence and the low-end relation hold by Proposition 40.5 with Corollary 39.38(i) and (ii); the eigenvalues are Proposition 39.42(ii); the exponent is Theorem 40.6(iii). □

Proposition 41.9 (The relations of a box are difference equations). *As stated.*

Proof. (i) By Definition 39.15(i) the symbols at the level $(\mathbf{a}, \mathbf{b})$ are the $(u; \mathbf{a}, \mathbf{b})$ with $u \in \mathbb{Z}^{\mathcal{E}}$ and $u_{\mathcal{E}} = c$, $c = \sum_j (a_j r_j + b_j r_j^*)$: a translate of the lattice $\{u_{\mathcal{E}} = 0\}$, of rank $n-1$. As $\kappa_{1,U} > 0$, the wall degree of g is at most $\mathfrak{t}$ exactly when $\kappa_U(g) + \mathfrak{t}\kappa_{1,U} \ge 0$ for every nonempty proper U (Definition 39.15(ii)). With $L(U) = \sum_j \big(a_j d_j(U) + b_j d_j^*(U)\big)$ and $\kappa_U(g) = u_U - L(U)$, the sets $U = \{e\}$ and $U = \mathcal{E} \setminus \{e\}$, nonempty and proper as $n \ge 2$, give

$$L(\{e\}) - \mathfrak{t}\kappa_{1,\{e\}} \le u_e \le c - L(\mathcal{E} \setminus \{e\}) + \mathfrak{t}\kappa_{1,\mathcal{E}\setminus\{e\}},$$

an interval of length at most $C(1+\mathfrak{t})$ with $C = \max_e \max\big(|c - L(\mathcal{E}\setminus\{e\}) - L(\{e\})|,\ \kappa_{1,\{e\}} + \kappa_{1,\mathcal{E}\setminus\{e\}}\big)$, which holds at most $C(1+\mathfrak{t}) + 1$ integers; and $u_{e_0} = c - \sum_{e \ne e_0} u_e$.

(ii) By Definition 39.15(iii) the letter identity of $g = (u; \mathbf{a}, \mathbf{b})$ for K_j has the terms g and $\theta_{j,T}(u + \mathbf{1}_T; \mathbf{a} + \mathbf{e}_j, \mathbf{b})$, $T \in \mathcal{B}_j$, and that for Ψ_j the terms g and $\theta_{j,T}(u + \mathbf{1}_{\mathcal{E}\setminus T}; \mathbf{a}, \mathbf{b} + \mathbf{e}_j)$; the mark relation at e has g and, for every j, the terms of the $T \in \mathcal{B}_j$ with $T \ni e$ at the level $(\mathbf{a} + \mathbf{e}_j, \mathbf{b})$ and of the $T \not\ni e$ at the level $(\mathbf{a}, \mathbf{b} + \mathbf{e}_j)$, at most $|\mathcal{B}_j|$ for each j, with coefficients affine in k. The shifts are the $(\mathbf{1}_T; \mathbf{e}_j, \mathbf{0})$ and the $(\mathbf{1}_{\mathcal{E}\setminus T}; \mathbf{0}, \mathbf{e}_j)$, $T \in \mathcal{B}_j$.

(iii) The letter identities have the coefficients 1 and $-\theta_{j,T}$, and the mark relations $m_{0,e} + k\, m_{1,e} + u_e$, $-(s_{0j} + k\, s_{1j} + a_j)\theta_{j,T}$ and $-(t_{0j} + k\, t_{1j} + b_j)\theta_{j,T}$, affine in k, with the stated parts in k. For a relation $\sum_g c_g g$, $e_G \sum_g c_g g = \sum_g c_g\, e_G g$, and $e_G g$ is the orbit average of the orbit of g (Definition 39.20(i)); so in the basis of the orbit averages the entry of an orbit is the sum of the c_g over its symbols, again affine in k, the part in k vanishing for the letter identities. □

Proposition 41.10 (What a reading by evaluation certifies). *As stated.*

Proof. (i) Gaussian elimination of the rows of A over $\Bbbk(k)$, the columns taken in the order of the ranking, highest first, gives a basis of the row space $\mathcal{R}^G_{\mathfrak{B}}$ in echelon form, with distinct leading orbits, and the leading orbit of every nonzero element of the row space is one of them; so these are the pivots P of Definition 39.20(ii), and $r = |P|$ is the rank. An element of the row space with zero coordinates on P would have a leading orbit outside P, so it is 0: the projection of $\mathcal{R}^G_{\mathfrak{B}}$ onto the coordinates P is injective, hence bijective. The chosen rows are a basis of $\mathcal{R}^G_{\mathfrak{B}}$, so $A_P(k)$ is invertible, and $E = A_P^{-1}[A_P \,|\, A_F]$, written on the columns P and F, is the basis of $\mathcal{R}^G_{\mathfrak{B}}$ with the identity on P, the unique one by the bijectivity; it is therefore the reduced echelon basis, whose row of a pivot p vanishes on the orbits ranked above p. For x with coefficients in $\Bbbk$, $x - x_P E$ is congruent to x and vanishes on P, so it is the reduction, $x_F - x_P A_P^{-1} A_F$ on F. The entries of A_P are affine in k, so $\det A_P$, not 0, has degree at most r. At k_0: the minors of order $r+1$ of A vanish identically, so $A(k_0)$ has rank at most r. If the minor of order r of the rows J' on the columns P does not vanish at k_0, then $E = A_{J',P}^{-1} A_{J'}$ as well, by the uniqueness, so E is regular at k_0, and $E(k_0)$ has the identity on P and the zeros of an echelon form, identities in k; its r independent rows lie in the row space of $A(k_0)$ and span it, so the elimination at k_0 has the pivots P and gives the reduction $x_F - x_P E_F(k_0)$, the value at k_0. Conversely, if the elimination at k_0 has the pivots P, the projection of the row space of $A(k_0)$ onto the coordinates P is injective, as above, so the columns P of $A(k_0)$ have rank r, and a minor of order r on them does not vanish.

(ii) The targets $f^{-1} b_i$ have their coefficients in $\Bbbk$. By (i) their reductions are $\big(x_F \det A_P - x_P \operatorname{adj}(A_P) A_F\big)/\det A_P$, the adjugate having entries of degree at most $r-1$ and A_F entries of degree at most 1; the entries of $\mathbf{B}$ are coefficients of these reductions (Definition 39.20(iii)). If N/D and N'/D' have numerators of degree at most d_1 and denominators of degree at most d_2 and agree at $d_1 + d_2 + 1$ points where D and D' do not vanish, then $ND' - N'D$, of degree at most $d_1 + d_2$, vanishes at these points and is 0. With a common denominator, two numerators of degree at most d_1 that agree at $d_1 + 1$ points are equal.

(iii) Write the coefficient of a free orbit c in the reduction of a target as $N_c/\det A_P$, $\deg N_c \le r$, by (ii). If the box is accepted at $\mathfrak{s}$ over $\Bbbk(k)$, every N_c with c outside the free Laurent orbits of wall degree at most $\mathfrak{s}$ vanishes, and at every k_0 with $\det A_P(k_0) \neq 0$ the elimination has the pivots P, so the same free orbits, and gives the values of the reductions: it accepts. If not, some such N_c is a nonzero polynomial, and at every k_0 with $\det A_P(k_0) N_c(k_0) \neq 0$ the elimination has the pivots P and its reduction has a nonzero coefficient on c: it rejects. The exceptions lie among the at most $2r$ zeros of $\det A_P$ and N_c.

(iv) Let $\mathbf{B}_{il} \neq \mathbf{B}'_{il}$, write $\mathbf{B}_{il} = N_{il}/\det A_P$ by (ii) and $\mathbf{B}'_{il} = N'_{il}/Q'$, and put $\Delta = N_{il} Q' - N'_{il} \det A_P$, a nonzero polynomial of degree at most $r+d$. At a strength k_0 with $Q'(k_0) \neq 0$ at which the elimination has the pivots P, it gives $\mathbf{B}(k_0)$, $\mathbf{B}$ being regular at k_0 by (i). If $\det A_P(k_0) \neq 0$,

agreement there gives $\Delta(k_0) = 0$; if $\det A_P(k_0) = 0$, then $N_{il} = \mathbf{B}_{il} \det A_P$ vanishes at k_0, $\mathbf{B}_{il}$ being regular there, and $\Delta(k_0) = 0$ again. So the strengths of agreement are among the at most $r + d$ zeros of Δ, and a uniformly drawn strength of S is one of them with probability at most $(r + d)/|S|$.

(v) The entries of A are q-integral, and reduction modulo q is a ring map, so the minors of order $r + 1$ of A vanish modulo q and $\det A_P$ modulo q is the determinant of A_P modulo q, which is not 0; the entries of $E = \operatorname{adj}(A_P)A_J/\det A_P$, A_J the chosen rows, reduce to those of $\bar{E} = \operatorname{adj}(\bar{A}_P)\bar{A}_J/\det \bar{A}_P$, which has the identity on P and the zeros of an echelon form. As in (i), $\bar{A}$ has the rank r and the pivots P over $\mathbb{F}_q(k)$, and its reductions $x_F - x_P\bar{E}_F$ are those over $\mathbb{Q}(k)$ taken modulo q; the proofs of (i) to (iv) use only linear algebra over a field and hold over $\mathbb{F}_q$. For the last claim, take an entry with $\mathbf{B}_{il} \neq \mathbf{B}'_{il}$ and write $\mathbf{B}_{il} = \tilde{N}/\tilde{D}$ and $\mathbf{B}'_{il} = N'/Q'$ with $\tilde{N}, \tilde{D}, N', Q' \in \mathbb{Z}[k]$ and $\tilde{D} = c_A \det A_P$ for a positive integer c_A; then $\Delta = \tilde{N}Q' - N'\tilde{D} \in \mathbb{Z}[k]$ is not 0. The finite set consists of the primes excluded above and those that divide c_A, every coefficient of Q', or every coefficient of Δ. For a prime outside it, $\mathbf{B}'$ modulo q is N'/Q' taken modulo q, Δ modulo q is a nonzero polynomial of degree at most $r + d$, and the argument of (iv) over $\mathbb{F}_q$ bounds the probability by $(r + d)/q$.

(vi) An element of $\mathcal{R}'$ lies in $\mathcal{R}^G_{\mathfrak{B}}$ with the same leading orbit, so the pivots of $\mathcal{R}'$ are pivots of $\mathcal{R}^G_{\mathfrak{B}}$, and the free orbits of $\mathcal{R}^G_{\mathfrak{B}}$ are free for $\mathcal{R}'$. So $\bar{x}$ is a combination of free orbits of $\mathcal{R}'$ with $x - \bar{x} \in \mathcal{R}'$. The free orbits of $\mathcal{R}'$ are independent modulo $\mathcal{R}'$, an element of $\mathcal{R}'$ that combines them having a free leading orbit and so being 0; so $\bar{x}$ is the reduction modulo $\mathcal{R}'$. □

Proposition 41.11 (Data with rational masses). *As stated.*

Proof. (i) Both data lie on the balance wall with the same exponents, so the origin $(\mathbf{m} - \mathbf{m}'; \mathbf{0}, \mathbf{0})$ has $(\mathbf{m} - \mathbf{m}')_{\mathcal{E}} = 0$ and lies on it too. The walls are linear in the data, so the walls along the ray at k are $\kappa_U(\mathbf{m}; \mathbf{s}, \mathbf{t}) + (k - 1)\kappa_U(\mathbf{m}'; \mathbf{s}, \mathbf{t})$, positive for real $k \geq 1$; by Lemma S20(iv) the values converge there and $\langle 1 \rangle_1 = P_F(\mathbf{m}; \mathbf{s}, \mathbf{t})$, the data at $k = 1$ being $(\mathbf{m}; \mathbf{s}, \mathbf{t})$.

(ii) The direction $N(\mathbf{m}; \mathbf{s}, \mathbf{t})$ is integral, on the balance wall, with the walls $N\kappa_U > 0$; its stride is $\alpha^{N\mathbf{m}} \prod_j K_j^{-Ns_j} \Psi_j^{-Nt_j} = f_{\mathbf{m}}^N$ on the positive orthant, and by Lemma S20(iv) at $k = \frac{1}{N}$, where the walls are the $\kappa_U > 0$, $\langle 1 \rangle_{1/N} = P_F(\mathbf{m}; \mathbf{s}, \mathbf{t})$. The wall degree is that of Definition 39.15(ii) with $\kappa_{1,U} = N\kappa_U$. □

Proposition 41.12 (One factorization serves every coefficient). *As stated.*

Proof. A_P is affine in k, so $A_P(k_0 + \epsilon) = M + \epsilon E$. For $|\epsilon| \, \|EM^{-1}\| < 1$, $M + \epsilon E = (I + \epsilon EM^{-1})M$ and $(M + \epsilon E)^{-1} = M^{-1} \sum_{j \geq 0} (-\epsilon EM^{-1})^j$, so $x_P(M + \epsilon E)^{-1} = \sum_j x_P M^{-1} (-EM^{-1})^j \epsilon^j$, which is the recursion. With $A_F(k_0 + \epsilon) = A_F(k_0) + \epsilon E_F$, $E_F = A_F(k_0 + 1) - A_F(k_0)$, the coefficient of ϵ^j, $j \geq 1$, in the reduction $x_F - x_P A_P^{-1} A_F$ is $-\lambda_j A_F(k_0) - \lambda_{j-1} E_F$. Each λ_j is a product of a row by E and one solve with the factorization of M. If N/D and N'/D', with the degree bounds and $D(k_0)D'(k_0) \neq 0$, have the same Taylor coefficients up to the order $d_1 + d_2$ at k_0, then $ND' - N'D = DD'(N/D - N'/D')$ vanishes to the order $d_1 + d_2 + 1$ at k_0 and has degree at most $d_1 + d_2$, so it is 0. □

Proposition 41.13 (The densities of a spanning set). *As stated.*

Proof. (i) A Laurent insertion b with real coefficients is real and continuous on the positive part of the chart, and $b\,\omega_0$ has the density $b\,\omega_0/dy$; the sets $\{f \geq t\}$, $t > 0$, are compact (proof of Proposition 40.2(i)), so $\mu_{f,b}$ is finite on $[t, f^\star]$, with $|\mu_{f,b}|$ at most the image of $|b|\,\omega_0$. Where $\int |b| f^{\operatorname{Re} k} \omega_0 < \infty$, $\langle b \rangle_k = \int b f^k \omega_0 = \int t^k \mu_{f,b}(dt)$ by the change of variables of an image measure. The proof of

Proposition 40.3(i), with the weight $b\,\omega_0/dy$ in place of ω_0/dy, gives a real-analytic density on $(0, f^\star)$; its positivity is not used there. The proof of Proposition 40.3(ii) uses Lemma S22(i), which allows every real-analytic weight w, here $w = b\,\omega_0/dy$, with $w(\log\alpha^\star) = b(\alpha^\star)\,(\omega_0/dy)(\alpha^\star)$; so the germ has the stated form with $g_b(0) = b(\alpha^\star)g(0)$.

(ii) Every monomial of b_l has an absolutely convergent value for large real k (Proposition 38.5(i)), so $\int t^{K_0} d|\mu_{f,b_l}| < \infty$ and $\int t^{K_0} d|t^{-1}\mu_{f,b_i}| < \infty$ for some K_0. Apply Lemma S21 to the measures $t^{-1}\mu_{f,b_i}$ and μ_{f,b_l} on $(0, f^\star]$ and the operators $Q(-1-\theta)$ and $-\tilde{P}_{il}(-1-\theta)$, whose adjoints are $Q(\theta)$ and $-\tilde{P}_{il}(\theta)$, $\theta^\dagger = -1-\theta$, with $Q(\theta)t^k = Q(k)t^k$. Its numbers are $M_E(k) = Q(k)\langle b_i\rangle_{k-1} - \sum_l \tilde{P}_{il}(k)\langle b_l\rangle_k$, which vanish for large k; by Lemma S21(i) the distribution E vanishes, and that is the system.

(iii) The identity $v(k-1) = \mathbf{B}(k)v(k)$ of meromorphic functions, iterated, gives $v(k-K+1) = \mathbf{B}(k-K+2)\cdots\mathbf{B}(k)\,v(k)$. Near $k = K$ the right side is holomorphic, the factors $\mathbf{B}(m)$, $2 \le m \le K$, being finite and v converging in a neighbourhood of K, the walls at K being positive; so the left side, v near 1, is holomorphic at 1 with the stated value. □

Proposition 41.14 (The native gauges of all exponents). *As stated.*

Proof. (i) K_j and Ψ_j are homogeneous of the degrees r_j and r_j^*, so by Euler's identity $\sum_e R_{j,e} = r_j$ and $\sum_e R^*_{j,e} = r_j^*$, and $\mathbf{u}(\alpha;\mathbf{s},\mathbf{t})\mathcal{E} = \sum_j (s_j r_j + t_j r_j^*)$: the balance wall. A native gauge of the ray is a point of X_F with $c_e^{(1)} = m_{1,e} - \sum_j \left(s_{1j}R_{j,e} + t_{1j}R^*_{j,e}\right) = 0$ for every e (Definitions 38.1 and 38.4), that is $\mathbf{m}_1 = \mathbf{u}(\alpha;\mathbf{s}_1,\mathbf{t}_1)$; for data on the balance wall with $m_{\mathcal{E}} \ne 0$ the target of Definition 8.17 is $\mathbf{m}$. The set is the graph of the regular map $(\alpha,\mathbf{s},\mathbf{t}) \mapsto \mathbf{u}(\alpha;\mathbf{s},\mathbf{t})$, isomorphic by the projection to $X_F \times \mathbb{C}^{2N}$; X_F is the complement in the torus $(\mathbb{C}^\times)^{\mathcal{E}}/\mathbb{C}^\times$, of dimension $n-1$, of the hypersurface $\prod_j K_j\Psi_j = 0$, which does not contain $\mathbf{1}$, so it is a nonempty open subset of an irreducible smooth variety, irreducible and smooth itself.

(ii) Let $\alpha_1,\dots,\alpha_\nu$ be the nondegenerate native gauges of the ray, w_1 its direction, and W the data on the balance wall, a vector space of dimension $n-1+2N$ with the coordinates $(m_e)_{e\ne e_0}$, $\mathbf{s}$, $\mathbf{t}$. In the coordinates $y_e = \log\alpha_e$, $e \ne e_0$, of the chart near each α_c, the map $(y,\mathbf{s},\mathbf{t}) \mapsto \big(\mathbf{u}(e^y;\mathbf{s},\mathbf{t});\mathbf{s},\mathbf{t}\big)$ into W is holomorphic, and its derivative is block triangular, with the identity on $(\mathbf{s},\mathbf{t})$ and the matrix $\big(\partial_{y_{e'}}\mathbf{u}_e\big)_{e,e'\ne e_0} = -\big(\partial_{y_{e'}}c_e^{(1)}\big)$, minus the Hessian of $\log f$ on the chart, which is nonsingular at α_c (Definition 38.4). By the holomorphic inverse function theorem there are disjoint neighbourhoods U_c of the α_c in X_F and a neighbourhood $\mathcal{W}$ of w_1 in W such that every $w \in \mathcal{W}$ has exactly one point native for it in each U_c. The exceptional set of Theorem 38.31(i), whose count concerns the critical points of the product of powers of the letters with the exponents of the direction, is a countable union of proper subvarieties; a proper subvariety is closed with empty interior in W, and its real points have empty interior in the real data, a polynomial that vanishes on an open set of real points being 0. By the Baire category theorem $\mathcal{W}$ contains data, real if need be, outside the exceptional set; at such data the native points are $(-1)^{n-1}\,\mathrm{eu}(X_F)$ in number, and they include the ν points in the U_c. □

Definition 41.15 (The procedure that finds native gauges by continuation). As stated.

Proof. (1) is Proposition 41.14(i). Steps (2) and (3) only propose points; nothing in the output rests on them. (4) In the coordinates α_e, $e \ne e_0$, of the chart the map $F = (c_e^{(1)})_{e\ne e_0}$ is rational, with no pole on a box Y on which no letter vanishes; read as a map of a real space of dimension $2(n-1)$, it is continuously differentiable there. Krawczyk's test asks for a point $\tilde{y} \in Y$, a nonsingular real matrix $\mathcal{Y}$ and an interval enclosure $F'(Y)$ of the derivative on Y with $\tilde{y} - \mathcal{Y}F(\tilde{y}) + (I - \mathcal{Y}F'(Y))(Y-\tilde{y}) \subseteq Y$. By the mean value theorem in integral form, $y - \mathcal{Y}F(y) = \tilde{y} - \mathcal{Y}F(\tilde{y}) + \int_0^1 \big(I - \mathcal{Y}F'(\tilde{y} + \tau(y -$

$\tilde{y}))\big)d\tau\,(y-\tilde{y})$, and the integral of matrices in the convex set $F'(Y)$ lies in it; so $y \mapsto y - \mathcal{Y}F(y)$ maps the compact convex set Y into itself and has a fixed point (Brouwer's fixed point theorem), a zero of F since $\mathcal{Y}$ is nonsingular. A zero of F in Y is a native gauge of the ray (Definition 38.4, the defects summing to 0 as f has degree 0, so that the defect at e_0 vanishes with the others). The Jacobian of F in the α_e is the Hessian of $\log f$ in the y_e times $\operatorname{diag}(\alpha_e^{-1})$, so an enclosure of the Hessian determinant that excludes 0 makes every native gauge in Y nondegenerate. Disjoint boxes hold distinct points, and distinct values of f at native gauges are distinct native values. □

50.41 Chapter 42: inputs along a ray

In this section $\vartheta = y\,d/dy$ on $(0,\infty)$, and for a function F on $(0,\infty)$, $\hat{F}(s) = \int_0^\infty y^{s-1}F(y)\,dy$ wherever it converges. Two facts about this Mellin read are used throughout.

Lemma S27. *Let F be smooth on $(0,\infty)$ with every $\vartheta^a F$ of size $O\big((1+|\log y|)^N\big)$ as $y \to 0$ and $O\big(y^C e^{-b\sqrt{y}}\big)$ as $y \to \infty$, for some N, C and $b > 0$. Then $\hat{F}$ is holomorphic on $\operatorname{Re} s > 0$, and:*

(i) for every polynomial r and $k \in \mathbb{N}$, $\int_0^\infty y^{s-1}\,y^k r(\vartheta)F\,dy = r(-s-k)\,\hat{F}(s+k)$ on $\operatorname{Re} s > 0$;

(ii) if $\hat{F}$ vanishes on a vertical line in $\operatorname{Re} s > 0$, then $F = 0$.

Proof. The bounds give absolute convergence, locally uniform on $\operatorname{Re} s > 0$, of every integral involved. (i) For $G = \vartheta^a F$ and $\operatorname{Re} a' > 0$, $\int_0^\infty y^{a'-1}\vartheta G\,dy = \int_0^\infty y^{a'}G'\,dy = \big[y^{a'}G\big]_0^\infty - a'\int_0^\infty y^{a'-1}G\,dy$, and the bracket vanishes at both ends by the bounds. So ϑ acts as $-a'$ under $\int_0^\infty y^{a'-1}(\cdot)\,dy$, and with $a' = s+k$ this gives the claim for every monomial $r(\vartheta) = \vartheta^a$, hence for every polynomial. (ii) With $y = e^v$ and $s = c + i\tau$, $\hat{F}(c+i\tau) = \int_{\mathbb{R}} e^{i\tau v}\,e^{cv}F(e^v)\,dv$ is the Fourier transform of the integrable continuous function $e^{cv}F(e^v)$; it vanishes for every τ, so that function vanishes (the uniqueness of the Fourier transform on $L^1(\mathbb{R})$), and $F = 0$. □

Definition 42.1 (Recurrences; the values input and the slope input). As stated.

Proof. The objects are well defined: L, L^* and L' act on functions on a coset of $\mathbb{Z}$, or on meromorphic functions, the coefficients being polynomials; the symbol is that of Corollary 38.7 for the coefficients c_i; the two inputs are inputs in the sense of Definition 5.4, a lattice input with the densities p and $\tilde{p}$ at the points of the coset beyond the cut, where both are finite because p is holomorphic there. □

Proposition 42.2 (The values of a ray as an input). *As stated.*

Proof. (i) By Theorem 38.14(i), $0 < f \le C'e^{-c'\|y\|}$ on the chart, so $\int_{y_{e_0}=0} |f^k|\,dy = \int f^{\operatorname{Re} k}\,dy$ converges for $\operatorname{Re} k > 0$, locally uniformly, and $\langle 1\rangle_k$ is holomorphic there. By Proposition 39.34 it continues to a meromorphic function p on $\mathbb{C}$, with $\lim_{k\to -j}(k+j)^{n-1}p(k) = V_1\,\mathsf{C}_j(1)$ for every $j \ge j(1) = 0$. The class $m = \sum_i c_i(k)\,\mathrm{Sh}^i[1]$ of the module (Definition 39.1) has the values $\langle m\rangle_k = \sum_i c_i(k)\langle f^i\rangle_k = \sum_i c_i(k)\langle 1\rangle_{k+i}$, which vanish for all large integers k; by Theorem 39.57, whose hypotheses are those of this statement, the continuation of $\langle m\rangle_k$ vanishes identically, and that continuation is $(Lp)(k)$. Multiply $(Lp)(k) = 0$ by $(k+j)^{n-1}$ and let $k \to -j$: for $i \le j$, $(k+j)^{n-1}p(k+i) \to V_1\,\mathsf{C}_{j-i}(1)$, and for $i > j$, $p(k+i)$ is holomorphic at $k = -j$, since $-j+i \ge 1$, so its product with $(k+j)^{n-1}$ tends to 0, $n \ge 2$. So $V_1\sum_{i\le\min(h,j)} c_i(-j)\,\mathsf{C}_{j-i}(1) = 0$, and $V_1 > 0$.

(ii) Differentiating $\sum_i c_i(x)p(x+i) = 0$ gives $\sum_i c_i'(x)p(x+i) + \sum_i c_i(x)p'(x+i) = 0$, that is $L\tilde{p} = L'p$.

(iii) By Proposition 38.9, $\langle 1\rangle_k > 0$ for large k and $\langle 1\rangle_{k+1}/\langle 1\rangle_k \to f(\alpha^\star)$, so the root rate of p along the integers is $f(\alpha^\star)$. For real $k \geq 1$, $\tilde{p}(k) = \int f^k \log(1/f)\, dy$ by differentiation under the integral, which the bound of (i) allows, and $|\tilde{p}(k)| \leq f(\alpha^\star)^{k-1} \int f\, |\log f|\, dy$ because $0 < f \leq f(\alpha^\star)$ on the chart (Theorem 38.14(i)). The last integral converges: $\log f$ is a combination of the coordinates y_e and of logarithms of the letters, polynomials with nonnegative coefficients in e^y, so $|\log f| \leq C(1 + \|y\|)$, while $f \leq C' e^{-c'\|y\|}$. So the root rate of $\tilde{p}$ is at most $f(\alpha^\star)$. □

Proposition 42.3 (Summation by parts at the cut). *As stated.*

Proof. For a function φ on the integers $x > -h$ with $\sum_x |R(x)|\,|\varphi(x)|$ and $\sum_x |R(x)\, c_i(x)\, \varphi(x+i)|$ finite over $x \geq 1$, which holds for $\varphi \in \{p, \tilde{p}\}$ since R and the c_i are polynomials and p, $\tilde{p}$ have root rate below one,

$$\sum_{x\geq 1} (L^*R)(x)\, \varphi(x) = \sum_{i=0}^{h} \sum_{x\geq 1} c_i(x-i) R(x-i)\, \varphi(x) = \sum_{i=0}^{h} \sum_{x' \geq 1-i} c_i(x') R(x')\, \varphi(x'+i),$$

with $x' = x - i$. The terms with $x' \geq 1$ add up to $\sum_{x'\geq 1} R(x')\, (L\varphi)(x')$, and those with $1 - i \leq x' \leq 0$, written $x' = -j$ with $0 \leq j < i$, to $\sum_{j=0}^{h-1} R(-j)\, B_j(\varphi)$, $B_j(\varphi) = \sum_{i=j+1}^{h} c_i(-j)\, \varphi(i-j)$. So

$$(\mathsf{T}_{0;(1)}[x]\, (L^*R)\, \varphi\, \mathbb{I}_{\mathbb{Z}})((0,\infty)) = \sum_{x\geq 1} R(x)\, (L\varphi)(x) + \sum_{j=0}^{h-1} R(-j)\, B_j(\varphi),$$

the Trailmoment at index zero on the counting input being the sum over the integers beyond the cut (Definition 6.1). For $\varphi = p$, $Lp = 0$ and $B_j(p) = \sum_{i>j} c_i(x) p(x+i)\big|_{x=-j} = -\beta_j(-j)$, which is the first identity. For $\varphi = \tilde{p}$, $L\tilde{p} = L'p$ (Proposition 42.2(ii), whose proof uses only $Lp = 0$), and the same rearrangement with L' in place of L gives $\sum_{x\geq 1} R(x)(L'p)(x) = (\mathsf{T}_{0;(1)}[x]\, (L'^*R)\, p\, \mathbb{I}_{\mathbb{Z}})((0,\infty)) - \sum_j R(-j) B'_j(p)$ with $B'_j(p) = \sum_{i>j} c'_i(-j)\, p(i-j)$. Hence the second identity holds with the boundary $B_j(\tilde{p}) - B'_j(p) = \sum_{i>j} \big(c_i(x)\tilde{p}(x+i) - c'_i(x)p(x+i)\big)\big|_{x=-j} = -\frac{d}{dx}\sum_{i>j} c_i(x)p(x+i)\big|_{x=-j} = \beta'_j(-j)$.

If every c_i with $i > j \geq 1$ vanishes to order two at $-j$, then near $x = -j$ each term of $\beta_j = -\sum_{i>j} c_i(x)p(x+i)$ is a polynomial with a double zero at $-j$ times a function holomorphic there, so $\beta_j(-j) = \beta'_j(-j) = 0$ for $j \geq 1$. □

Proposition 42.4 (The fixed block). *As stated.*

Proof. (i) For R of degree d with leading coefficient $\rho \neq 0$, $c_i(x-i)R(x-i)$ has degree at most $D + d$ and coefficient $[x^D]c_i\, \rho$ at x^{D+d}, so L^*R has degree at most $D + d$ and coefficient $\chi(1)\rho \neq 0$ there. So L^* is injective on $\Bbbk[x]$, and for every d it maps the polynomials of degree at most d, a space of dimension $d + 1$, into those of degree at most $D + d$, meeting the polynomials of degree below D only in 0. The dimensions add up, $(d+1) + D = D + d + 1$, so the polynomials of degree at most $D + d$ are the direct sum of the two, for every d; this is the decomposition of $\Bbbk[x]$.

(ii) Write $W = L^*B + r$ with $\deg r < D$ by (i), and $L'^*B = L^*B_2 + r_2$ in the same way; B, r, B_2, r_2 have coefficients in $\Bbbk$. By Proposition 42.3,

$$(\mathsf{T}_{0;(1)}[x]\, W\, p\, \mathbb{I}_{\mathbb{Z}})((0,\infty)) = (\mathsf{T}_{0;(1)}[x]\, r\, p\, \mathbb{I}_{\mathbb{Z}})((0,\infty)) - \sum_j B(-j)\, \beta_j(-j),$$

$$(\mathsf{T}_{0;(1)}[x]\, W\, \tilde{p}\, \mathbb{I}_{\mathbb{Z}})((0,\infty)) = (\mathsf{T}_{0;(1)}[x]\, r\, \tilde{p}\, \mathbb{I}_{\mathbb{Z}})((0,\infty)) + (\mathsf{T}_{0;(1)}[x]\, r_2\, p\, \mathbb{I}_{\mathbb{Z}})((0,\infty))$$

$$-\sum_{j} B_2(-j)\,\beta_j(-j)+\sum_{j} B(-j)\,\beta'_j(-j).$$

A polynomial of degree below D is a $\Bbbk$-combination of the $(x-1)^a$, $a<D$, and the Trailmoment at index zero is linear in the density, which gives the claim. □

Corollary 42.5 (A mark opened at an integer strength). *As stated.*

Proof. The bunch $B=\{e\}$ has width one, $c(\{e\})=r(\{e\})+r(R)-r(\mathcal{E})=1$ since e is neither a loop nor a coloop, and the unit weights factor across B and R. Its minors on B are $\mathcal{B}|B$, with the one basis $\{e\}$, and $\mathcal{B}/R$, with the one basis $\varnothing$; so the bunch family of Theorem 19.13 has the period 1, and the hinge ratio of B is $\varrho_B=\mathbf{E}_{\mathcal{B}/R}/\mathbf{E}_{\mathcal{B}|B}=\alpha_e/\alpha_e=1$ (Definition 19.2). The room family is the deletion $\mathcal{B}\setminus e=\mathcal{B}|R$ at the level d and the contraction $\mathcal{B}/e=\mathcal{B}/B$ at the level r, and $\varrho_R=\mathbf{E}_{\mathcal{B}/e}/\mathbf{E}_{\mathcal{B}\setminus e}=X_{/}/X_{\setminus}$, since $\mathbf{E}=K\Psi=\alpha^R K(\alpha)K(\alpha^{-1})$ for each of them. At the centre $(s\mathbf{1};s,s)$ the wall of B is $\kappa_B=s\,c(B)=s$ (Proposition 8.21(ii)), so the odd share is fixed at $2\delta^d=s-\kappa_B=0$ and the level shares are $(a^d,b^d,a^r,b^r)=(d,d,s-d,s-d)$, d the even share. The one-table display of Theorem 19.13 reads

$$\Gamma(s)^2P_{\mathcal{B}}(s\mathbf{1};s,s)=\frac{1}{2\pi i}\int\Gamma(d)^2\,\Gamma(s-d)^2\,\Phi_s(d)\,dd,\qquad \Phi_s(d)=\int_{y_{e_0}=0}X_{\setminus}^{-d}X_{/}^{-(s-d)}\,dy,$$

the room period at the masses $s\mathbf{1}_R$, whose integrand is $\alpha^{s\mathbf{1}_R}K_{\setminus}^{-d}\Psi_{\setminus}^{-d}K_{/}^{-(s-d)}\Psi_{/}^{-(s-d)}=X_{\setminus}^{-d}X_{/}^{-(s-d)}$.

When $X_\flat=X_{\setminus}$, $\sup\varrho_B=1<\inf\varrho_R$, and Corollary 19.21(i) gives $P_{\mathcal{B}}(s\mathbf{1};s,s)=\sum\text{Res}$ over the poles of $\Gamma(d)^2$ at $d=-x$, $x\in\mathbb{N}$, where the two lattices of the level d coincide, every room period there converging. Then $\Phi_s(-x)=q_s(x)$. When $X_\flat=X_{/}$, $\inf\varrho_B>\sup\varrho_R$, and the same corollary closes on the level r with the opposite sign; the substitution $d=s-\tau$ exchanges the two levels and the two minors and turns that closing into the closing at $\tau=-x$, with $\Phi_s(s-\tau)=\int X_{/}^{-\tau}X_{\setminus}^{-(s-\tau)}\,dy$ and $q_s(x)=\Phi_s(s+x)$. In both cases, writing $\Phi^\flat(\tau)=\int X_\flat^{-\tau}X_\sharp^{-(s-\tau)}\,dy$, so that $q_s(x)=\Phi^\flat(-x)$, the room periods $\Phi^\flat(-x)$, $x\in\mathbb{N}$, converge. The walls of the room family with the minor of $X_\flat$ at the share $-x$ and that of $X_\sharp$ at $s+x$, at the masses $s\mathbf{1}_R$, are $\kappa_S=-x\,c_\flat(S)+(s+x)\,c_\sharp(S)$ with the widths $c_\flat$, $c_\sharp$ of the two minors, by the computation of Proposition 8.21(ii), which is linear in the strengths; they are affine in x and positive at every point of $\mathbb{N}$ (Theorem 8.7), hence on $[0,\infty)$ and on a neighbourhood of it, so q_s converges and is holomorphic there. The closing reads

$$\Gamma(s)^2P_{\mathcal{B}}(s\mathbf{1};s,s)=\sum_{x\in\mathbb{N}}\operatorname*{Res}_{\tau=-x}\Big(\Gamma(\tau)^2\,\Gamma(s-\tau)^2\,\Phi^\flat(\tau)\Big).$$

At the integer s, $\Gamma(s-\tau)=(s-1-\tau)\cdots(1-\tau)\,\Gamma(1-\tau)$, so $\Gamma(\tau)^2\Gamma(s-\tau)^2=V_s(-\tau)\,\Gamma_{0}^{4}\big[\tau,\ \tau,\ 1-\tau,\ 1-\tau\big]$, and by Lemma 5.16 the last factor has at $\tau=-x$ the principal part $(\tau+x)^{-2}$ and no simple part. The residue is therefore the derivative of $V_s(-\tau)\Phi^\flat(\tau)$ at $\tau=-x$,

$$-V_s'(x)\,q_s(x)+V_s(x)\,\Phi^{\flat\prime}(-x)=V_s(x)\,\tilde q_s(x)-V_s'(x)\,q_s(x),$$

since $\Phi^{\flat\prime}(-x)=-q_s'(x)$. The ratio $X_\flat/X_\sharp$ is at most ρ, so $0<q_s(x)\le\rho^x q_s(0)$ and, by differentiation under the integral, $|\tilde q_s(x)|\le\rho^{x-1}\int\log(X_\sharp/X_\flat)\,(X_\flat/X_\sharp)\,X_\sharp^{-s}\,dy$ for $x\ge1$, the last integral being $\tilde q_s(1)$, finite by the holomorphy at 1; with V_s a polynomial the terms have root rate at most ρ. □

Proposition 42.6 (Boundary relations). *As stated.*

Proof. The identity $Lp = 0$ reads $\beta_{x_0,j}(x) = -\sum_{i>j} c_i(x)\, p(x+i)$ near x_0, and the right side is holomorphic at x_0 by the hypothesis; so is $\beta_{x_0,j}$, and the first relation is this identity at x_0. Differentiating it at x_0 gives $\beta'_{x_0,j}(x_0) = -\sum_{i>j} \big(c_i'(x_0)p(x_0+i) + c_i(x_0)p'(x_0+i)\big)$, which is the second relation since $\tilde p = -p'$. $\beta_{x_0,j} = \sum_{i\le j} c_i\, p(\cdot + i)$ is a finite sum of products of the Taylor expansions of the c_i at x_0 with the Laurent expansions of p at $x_0 + i$; its value and its derivative at x_0 are the coefficients of $(x-x_0)^0$ and $(x-x_0)^1$ of that sum, finitely many products of these coefficients.

When c_h has no zero at the integers $x \ge 1$, $L\tilde p = L'p$ at x expresses $\tilde p(x+h)$ through $\tilde p(x), \dots, \tilde p(x+h-1)$ and values of p, so by induction every $\tilde p(x)$, $x \ge 1$, is an affine function of $\tilde p(1), \dots, \tilde p(h)$; for an integer x_0 with $x_0 + j \ge 0$ the slopes in the second relation are at the integers $x_0 + i \ge 1$, $i > j$, and the relation is affine in the initial slopes.

At the cut of the values of a ray, Proposition 42.2(i) at $j = 0$ gives $p(x) = V_1 x^{-(n-1)}(1 + O(x))$, $\mathsf{C}_0(1) = 1$, so $\mathsf{L}_0 = V_1$, and p has a pole of order exactly $n-1$ at 0. $\beta_{0,0} = c_0\, p$ is holomorphic at 0, so c_0 vanishes to order at least $n-1$ there, and $c_0(x)p(x) = \gamma_{n-1}\mathsf{L}_0 + (\gamma_{n-1}\mathsf{L}_1 + \gamma_n \mathsf{L}_0)\, x + O(x^2)$. The two relations at $x_0 = 0$, $j = 0$ are therefore the displayed ones; the first is the low-end relation of Corollary 39.38. When every table has unit weights, the values are $\langle 1\rangle_k = P_F(kq)$ for the question q of the direction (Definition 17.1), the direction being a point of the balance wall with real data, and Theorem 17.5(i) gives $k^{n-1}P_F(kq) = V_1 + o(k)$ as $k \downarrow 0$, every $\log \theta_{j,T}$ being 0; since $k^{n-1}p(k) = \mathsf{L}_0 + \mathsf{L}_1 k + O(k^2)$ is holomorphic at 0, $\mathsf{L}_1 = 0$. □

Proposition 42.7 (Minimality). *As stated.*

Proof. (i) Let $D = \deg c_h$. Divided by $c_h(x)$, which has no zero at the integers $x \ge 1$, the recurrence reads $u(x+h) + \sum_{i<h} a_i(x)\, u(x+i) = 0$ with $a_i = c_i/c_h \to [x^D]c_i/[x^D]c_h$ as $x \to \infty$, and $a_0(x) \ne 0$ at these integers. The limit characteristic polynomial is $\chi(\lambda)/[x^D]c_h$, of degree h, with $\chi(0) = [x^D]c_0 \ne 0$ and roots λ_c of distinct moduli. Perron's theorem on such recurrences (coefficients with limits, a_0 without zeros on the range, roots of the limit polynomial of distinct moduli) gives a basis $u_1, \dots, u_h$ of the solutions on the integers $x \ge 1$ with $u_c(x+1)/u_c(x) \to \lambda_c$, so $|u_c(x)|^{1/x} \to |\lambda_c|$. Let $u = \sum_c b_c u_c \ne 0$, and let d be the index with the largest $|\lambda_d|$ among the c with $b_c \ne 0$. For the other such c, $u_c(x)/u_d(x) \to 0$, the root rates being smaller; so $u(x) = b_d u_d(x)\,(1 + o(1))$, $u(x+1)/u(x) \to \lambda_d$, and u has the root rate $|\lambda_d|$. Hence u has root rate at most λ exactly when $b_c = 0$ for every c with $|\lambda_c| > \lambda$, and U_λ is spanned by the u_c with $|\lambda_c| \le \lambda$, which are independent.

(ii) $\tilde p$ satisfies $L\tilde p = L'p$ (Proposition 42.2(ii), whose proof uses only $Lp = 0$) and has root rate at most λ; a φ with the same two properties differs from it by $u = \varphi - \tilde p$ with $Lu = 0$ and root rate at most λ, the root rate of a difference being at most the larger of the two; conversely every $\tilde p + u$, $u \in U_\lambda$, has both properties. The same holds for $L\varphi = 0$ with p. A second relation of Proposition 42.6 at an integer x_0 with $x_0 + j \le 0$ holds for $\tilde p + u$ exactly when its left side vanishes on u, since its right side is read off the Laurent data of p at $x_0, \dots, x_0 + j \le 0$ and involves no slope; relations at other points are consequences of $L\tilde p = L'p$ and single out nothing; so if these left sides vanish together on no nonzero $u \in U_\lambda$, $\tilde p$ is the only solution of root rate at most λ that satisfies the relations. The first relations single out p in the same way. □

Proposition 42.8 (The two ends paired). *As stated.*

Proof. (i) For $\sigma < 0$ every term vanishes. For $\sigma \ge 0$, $c_i(\sigma - i) = \epsilon\, c_i(-\sigma)$ by the hypothesis read at $x = -\sigma$, so the sum is $\epsilon \sum_{i=0}^{\min(h,\sigma)} c_i(-\sigma)\, \mathsf{C}_{\sigma-i}$, which vanishes by Proposition 42.2(i) at $j = \sigma$.

(ii) Write $p(x) = \langle 1\rangle_x$, and $(L^*\mathsf{C})(\sigma) = \sum_i c_i(\sigma - i)\mathsf{C}_{\sigma-i}$. Shifting j by one,

$$B(\sigma+1) = \sum_{i=1}^{h}\sum_{j=0}^{i-1} c_i(\sigma - j)\,\mathsf{C}_{\sigma-j}\,p(\sigma - j + i),$$

and the difference with $B(\sigma)$ keeps the term $j = 0$ of the first sum and the term $j = i$ of the second:

$$B(\sigma+1) - B(\sigma) = \sum_{i=1}^{h}\big(c_i(\sigma)\,\mathsf{C}_\sigma\,p(\sigma+i) - c_i(\sigma-i)\,\mathsf{C}_{\sigma-i}\,p(\sigma)\big) = \mathsf{C}_\sigma\,(Lp)(\sigma) - p(\sigma)\,(L^*\mathsf{C})(\sigma),$$

the terms $i = 0$ cancelling. For integers $\sigma \geq 1$ both vanish, by Proposition 42.2(i) and by (i). At $\sigma = 1$ only $j = 1$ has $\mathsf{C}_{1-j} \neq 0$, with $\mathsf{C}_0 = 1$, so $B(1) = \sum_{i\geq 1} c_i(0)\,p(i)$, which is $-\gamma_{n-1}V_1$ by Proposition 42.6.

(iii) By Proposition 42.6, c_0 vanishes to order at least $n-1$ at 0; with $\deg c_0 \leq n-1$ and $c_0 \neq 0$, $c_0 = \gamma_{n-1}x^{n-1}$, $\gamma_{n-1} \neq 0$, and the coefficients of x^{n-1} give $\chi(\lambda) = \sum_i [x^{n-1}]c_i\lambda^i$ with $\chi(0) = \gamma_{n-1}$. On the centre ray of a family, $\alpha^\star = \mathbf{1}$ and $\langle 1\rangle_k = P_F(kq)$ for the centre question q; Theorem 17.5(ii) at the centre, with $-\nabla^2 X(0) = 4H$ on the chart in the coordinates $z = y/2$ (H as in Theorem 38.15) and $e^{X(0)} = f(\mathbf{1})$, gives

$$\langle 1\rangle_k = f(\mathbf{1})^k\Big(\frac{2\pi}{k}\Big)^{\frac{n-1}{2}}(\det H)^{-1/2}\big(1 + O(k^{-1})\big),$$

the factor 2^{n-1} of that theorem cancelling against $\det(4H)^{1/2} = 2^{n-1}(\det H)^{1/2}$. Theorem 39.57 at $g = 1$ gives $j^{(n-1)/2}f(\mathbf{1})^j\mathsf{C}_j(1) \to (2\pi)^{-(n-1)}a_0(1)$, where $a_0(1) = (2\pi)^{(n-1)/2}(dy/dv)(\mathbf{1}) = (2\pi)^{(n-1)/2}(\det H)^{-1/2}$ by Theorem 38.6(i), the coordinates v having $\frac12\sum v_i^2 = \frac12 y^{\mathsf{T}}Hy + O(|y|^3)$. So for fixed i, as $a \to \infty$, $\mathsf{C}_a\,\langle 1\rangle_{a+i} = \lambda_\star^i(\det H)^{-1}a^{-(n-1)}(1 + o(1))$, with $\lambda_\star = f(\mathbf{1})$, while $c_i(a) = [x^{n-1}]c_i\,a^{n-1} + O(a^{n-2})$. Every term of $B(\sigma)$ with $a = \sigma - j$ therefore tends to $[x^{n-1}]c_i\,\lambda_\star^i(\det H)^{-1}$, and

$$\lim_{\sigma\to\infty} B(\sigma) = (\det H)^{-1}\sum_{i=1}^{h} i\,[x^{n-1}]c_i\,\lambda_\star^i = (\det H)^{-1}\lambda_\star\chi'(\lambda_\star).$$

By (ii) the limit is $-\chi(0)V_1$, so $V_1 \det H = -\lambda_\star\chi'(\lambda_\star)/\chi(0)$, which is positive. The symbol vanishes at $\lambda_\star$: $\langle 1\rangle_{k+1}/\langle 1\rangle_k \to \lambda_\star$ (Proposition 38.9, a limit that needs no hypothesis on the coefficients of L), so dividing $\sum_i c_i(k)\langle 1\rangle_{k+i} = 0$ by $k^{n-1}\langle 1\rangle_k$ and letting $k \to \infty$ gives $\chi(\lambda_\star) = 0$; writing $\chi(\lambda) = \chi(0)\prod_c(1 - \lambda/\lambda_c)$ over its roots with multiplicity, a multiple root at $\lambda_\star$ would give $\chi'(\lambda_\star) = 0$, so $\lambda_\star$ is simple, and $\lambda_\star\chi'(\lambda_\star) = -\chi(0)\prod_{c\neq\star}(1 - \lambda_\star/\lambda_c)$. □

The rest of this section reads the list $\binom{\mathcal{E}}{1}$. There $\mathsf{g}(y) = \mathsf{G}_{0;(1,-1)}(1,y) = \int_0^\infty x^{-1}e^{-x-y/x}\,dx$ and $\mathsf{h}(y) = \sum_{m\geq 0} y^m/m!^2$. The configuration $(1,-1)$ on one scale has $\mathrm{cone}(t) = \mathbb{R}$, so $\mathsf{G}_{\nu;(1,-1)}(1,y)$ is entire in ν (Theorem 2.2); its ladder and its exchange relation (Theorem 2.4(i),(ii)) read $\partial_y\mathsf{G}_{\nu;(1,-1)}(1,y) = -\mathsf{G}_{\nu-1;(1,-1)}(1,y)$ and $\nu\,\mathsf{G}_{\nu;(1,-1)}(1,y) = \mathsf{G}_{\nu+1;(1,-1)}(1,y) - y\,\mathsf{G}_{\nu-1;(1,-1)}(1,y)$. So $\vartheta\mathsf{g} = -y\,\mathsf{G}_{-1;(1,-1)}(1,y)$, the exchange relation at $\nu = -1$ gives $y\,\mathsf{G}_{-2;(1,-1)}(1,y) = \mathsf{g} + \mathsf{G}_{-1;(1,-1)}(1,y)$, and

$$\vartheta^2\mathsf{g} = -y\,\mathsf{G}_{-1;(1,-1)}(1,y) + y^2\mathsf{G}_{-2;(1,-1)}(1,y) = y\,\mathsf{g};$$

and $\vartheta^2\mathsf{h} = \sum_{m\geq 1} y^m/(m-1)!^2 = y\,\mathsf{h}$. By Lemma 20.29(i) at $l = 0$, $\mathsf{g} = -\mathsf{h}\log y + \tilde{\mathsf{g}}$ with the entire function $\tilde{\mathsf{g}}(y) = \sum_m 2(\log\Gamma)'(1+m)\,y^m/m!^2$. The solutions of $\vartheta^2 u = yu$ on $(0,\infty)$ form a space

$\mathcal{V}$ of dimension two with the basis g, h, the two being independent since g/h is not constant; the $n+1$ products $\mathsf{g}^{n-j}\mathsf{h}^j$ are independent as well, h^n times the powers of the nonconstant function g/h.

Proposition 42.9 (The native gauges of $\binom{\mathcal{E}}{1}$). *As stated.*

Proof. (i) The occupation of e is $R_e = \alpha_e \partial_{\alpha_e} \log K = u_e$, and since $\Psi(\alpha) = \alpha^{\mathcal{E}} K(\alpha^{-1})$ the dual occupation is $R_e^* = \alpha_e \partial_{\alpha_e} \log \Psi = 1 - v_e$, $v_e = \alpha_e^{-1} / K(\alpha^{-1})$. The defect of the direction (Definition 38.1) is $c_e^{(1)} = m - s\,u_e - t\,(1 - v_e) = \frac{s-t}{n} - s\,u_e + t\,v_e$, by the balance $m - t = \frac{s-t}{n}$. On X_F the α_e, $K(\alpha)$ and $K(\alpha^{-1})$ are nonzero, so $u_e, v_e \neq 0$, $u_e v_e = \lambda(\alpha) \neq 0$ for every e, and $\sum_e u_e = \sum_e v_e = 1$.

Let α be a native gauge, $c_e^{(1)} = 0$ for every e. With $v_e = \lambda/u_e$, $s\,u_e^2 - \frac{s-t}{n} u_e - t\lambda = 0$ for every e: the occupations are roots of one quadratic, whose roots u_+, u_- have $u_+ + u_- = \frac{s-t}{ns}$ and $u_+ u_- = -t\lambda/s \neq 0$. Let u_+ be taken on $n-j$ marks and u_- on j marks, u_- on none when the occupations are all equal; $\sum_e u_e = 1$ gives $(n-j)u_+ + j u_- = 1$, and with $u_- = \frac{s-t}{ns} - u_+$, $(n-2j)u_+ = 1 - j\frac{s-t}{ns}$. At $2j = n$ this would read $1 = \frac{s-t}{2s}$, that is $s = -t$, which is excluded. Conversely let the occupations of $\alpha \in X_F$ take the value u_+ on $n-j$ marks and u_- on j marks with the three relations. Adding $(n-j)u_+ + j u_- = 1$, which follows from them, to $(n-j)u_- + j u_+$ gives $n(u_+ + u_-) = \frac{s-t}{s}$, so $(n-j)u_- + j u_+ = -\frac{t}{s}$ and

$$\lambda^{-1} = \sum_e \frac{1}{u_e} = \frac{n-j}{u_+} + \frac{j}{u_-} = \frac{(n-j)u_- + j u_+}{u_+ u_-} = -\frac{t}{s\,u_+ u_-},$$

using $\sum_e v_e = 1$, $v_e = \lambda/u_e$. Then $s\,u_e - t\,v_e = s\,u_e + s\,u_+ u_-/u_e = s(u_+ + u_-) = \frac{s-t}{n}$ at both values, so every defect vanishes. Since $\alpha_e = u_e K(\alpha)$, such a point is $(u_e)_e$ up to scale; conversely, for given $u_\pm$ with the three relations and a set of j marks, the point $u = (u_e)_e$ has $K(u) = 1$ and $\Psi(u) = \prod_e u_e \sum_e u_e^{-1} = -\prod_e u_e\, t/(s\,u_+ u_-) \neq 0$, so it lies in X_F. The relations for the complement of the set, its $n-j$ marks at the value u_+ in the role of u_- and the other j at u_- in the role of u_+, hold as well: the second is symmetric, and $(n-j)u_+ + j u_- = 1$ with $u_+ = \frac{s-t}{ns} - u_-$ gives $(2j-n)u_- = 1 - (n-j)\frac{s-t}{ns}$; so a set and its complement give the same point. The stride $f = \alpha^{m\mathbf{1}} K^{-s} \Psi^{-t} = \alpha^{(m-t)\mathbf{1}} K(\alpha)^{-s} K(\alpha^{-1})^{-t}$ is homogeneous of degree 0, and at u, where $K(u) = 1$ and $K(u^{-1}) = \lambda^{-1}$, it is $\big(\prod_e u_e\big)^{m-t} \lambda^t$.

(ii) At $s = t = \sigma$ the balance gives $m = \sigma$, the relations give $u_- = -u_+$ and $u_+ = 1/(n-2j)$, so u is $1/(n-2j)$ times the sign η with $\eta_e = -1$ exactly on the j marks; on the chart $\alpha_{e_0} = 1$ the native gauge is the sign $\eta_{e_0}\eta$, with $K \neq 0$. Conversely every sign with $K(\eta) \neq 0$ is a native gauge (Theorem 38.17(ii)). The native value is $\lambda^\sigma = u_+^{2\sigma} = (n-2j)^{-2\sigma} = K(\eta)^{-2\sigma}$, and $|n-2j|$ for $0 \le j \le n$, $2j \neq n$, takes the $\lceil n/2 \rceil$ values $n, n-2, \dots$ down to 1 or 2. By Theorem 38.17(ii) the Hessian is $2\sigma\big(\kappa_\eta(X_e, X_{e'})\big)_{e,e' \neq e_0}$, the covariances of the indicators under $\mathbb{P}_\eta(\{e\}) = \pi_e = \eta_e/K(\eta)$. The indicator X_e takes the value 1 at the basis $\{e\}$ and 0 at the others, so $\kappa_\eta(X_e, X_{e'}) = \delta_{ee'}\pi_e - \pi_e \pi_{e'}$. The determinant of a diagonal matrix less a matrix of rank one, $\det\big(\operatorname{diag}(\pi_e) - \pi\pi^{\mathsf{T}}\big)_{e,e' \neq e_0} = \prod_{e \neq e_0} \pi_e \big(1 - \sum_{e \neq e_0} \pi_e\big)$, is $\prod_e \pi_e$ since $\sum_e \pi_e = 1$, and the Hessian has the determinant $(2\sigma)^{n-1} \prod_e \eta_e / K(\eta)^n \neq 0$. □

Proposition 42.10 (A parallel class enters through its list). *As stated.*

Proof. (i) Theorem 21.5 with every mark replaced by the first rule gives $K_{\mathcal{B}} = K_{\mathcal{H}}\big((e_1(\alpha_{P_i}))_i\big) = K_{\mathcal{H}}(A)$, the weights of a list being one. Write $K_{\mathcal{H}}(A)^k = \sum_w \big([A^w] K_{\mathcal{H}}^k\big) A^w$ and $A^w = \prod_i \sum_{v_i \in \mathbb{N}^{P_i},\ |v_i| = w_i} \binom{w_i}{v_i} \alpha^{v_i}$. The classes are disjoint, so a monomial α^v determines $w_i = v_{P_i}$, and it occurs only in the term of that w, with the coefficient $\big([A^w] K_{\mathcal{H}}^k\big) \prod_i \binom{w_i}{v|_{P_i}}$.

(ii) On the centre ray at the strength one, $f^{-1} = K_{\mathcal{B}}(\alpha)K_{\mathcal{B}}(\alpha^{-1})$ (Corollary 39.36), and $\mathsf{C}_k^{\mathcal{B}}(1)$ is the constant term of $K_{\mathcal{B}}(\alpha)^k K_{\mathcal{B}}(\alpha^{-1})^k$ (Definition 39.30, the origin form being dy), which is $\sum_v \big([\alpha^v]K_{\mathcal{B}}^k\big)^2$, the coefficients being real. By (i) this is $\sum_w \big([A^w]K_{\mathcal{H}}^k\big)^2 \prod_i \sum_{|v_i|=w_i} \binom{w_i}{v_i}^2$, and $\sum_{|v_i|=w_i} \binom{w_i}{v_i}^2 = \sum_{v_i} \big([\alpha^{v_i}]K_{P_i}^{w_i}\big)^2$ is the constant term of $\big(K_{P_i}(\alpha)K_{P_i}(\alpha^{-1})\big)^{w_i}$, $K_{P_i} = \sum_{e\in P_i}\alpha_e$, the closing of $\binom{P_i}{1}$; for $|P_i| = 1$ it is 1.

(iii) At a sign, (i) gives $K_{\mathcal{B}}(\eta) = K_{\mathcal{H}}\big((\sum_{e\in P_i}\eta_e)_i\big)$, and the sum of s_i signs takes the values $s_i, s_i - 2, \dots, -s_i$; the native values are those of Theorem 38.17(ii) for one table at the strength σ. □

Proposition 42.11 (A mark added is a closing of the critical-line kernel). *As stated.*

Proof. (i) By the display of Section 42.6 at the centre, from Corollary 18.24 and Proposition 8.15, $\Gamma(s)^2 p_{n+1}(s)$ is, for real $s > 0$, the share integral $\int_{a_1+\dots+a_{n+1}=s} \prod_e \Gamma(a_e)^2$ of Corollary 18.24, which converges absolutely, $|\Gamma(c+iy)|$ decaying like $e^{-\pi|y|/2}$. In the coordinates $(a_1, \dots, a_{n-1}, d)$ with $d = a_1 + \dots + a_n$, of Jacobian one, Fubini's theorem splits it into the integral over $\operatorname{Re} d = c$ of $\Gamma(s-d)^2$ times the share integral of n marks at the total d. That inner integral is holomorphic in d on $\operatorname{Re} d > 0$, by absolute and locally uniform convergence, and equals $\Gamma(d)^2 p_n(d)$ at real d by the same display at n marks; so it equals $\Gamma(d)^2 p_n(d)$ on $\operatorname{Re} d > 0$, p_n being holomorphic there by the bound of Theorem 38.14(i), as in the proof of Proposition 42.2(i). This gives the formula at real s; both sides are holomorphic in s on $\operatorname{Re} s > c$, so it holds on $\operatorname{Re} s > 0$. At $s = 1$ and $c = \frac12$, with $d = \frac12 + iy$, the kernel $\Gamma(d)^2\Gamma(1-d)^2$ is $2\pi\, p_{\mathrm{crit}}(y)$ (Definition 36.1) and $dd/(2\pi i) = dy/(2\pi)$.

(ii) At the integer s, $\Gamma(s-d) = (s-1-d)\cdots(1-d)\,\Gamma(1-d)$, so the integrand of (i) is $\Gamma_0^4\big[d,\ d,\ 1-d,\ 1-d\big]\ G(d)$ with $G = W_s\, p_n$, which has double zeros at $1, \dots, s-1$. On $\operatorname{Re} d \geq 1$, $|p_n(d)| \leq p_n(\operatorname{Re} d) \leq 4^{1-\operatorname{Re} d} p_n(1)$, since $0 < (K(\alpha)K(\alpha^{-1}))^{-1} \leq n^{-2} \leq \frac14$ on the chart (Theorem 38.14(i)); and $\big|\Gamma_0^4\big[d,\ d,\ 1-d,\ 1-d\big]\,\big| = \pi^2/|\sin\pi d|^2$ is at most $\pi^2/\cosh^2(\pi \operatorname{Im} d)$ on the lines $\operatorname{Re} d = N + \frac12$ and at most $Ce^{-2\pi|\operatorname{Im} d|}$ for $|\operatorname{Im} d| \geq 1$. So the integrals over the lines $\operatorname{Re} d = N + \frac12$ and over the horizontal segments $|\operatorname{Im} d| = Y$ tend to 0, and moving the line to the right (Theorem 4.5) gives $-\sum_{m\geq 1} \operatorname{Res}_{d=m}$. By Lemma 5.16 the kernel has at $d = m$ the principal part $(d-m)^{-2}$ and no simple part, so the residue is $G'(m)$, zero for $m < s$, and

$$\Gamma(s)^2 p_{n+1}(s) = -\sum_{m\geq 1} \big(W_s\, p_n\big)'(m) = \sum_{m\geq 1} \big(W_s(m)\, \tilde p_n(m) - W_s'(m)\, p_n(m)\big),$$

the series converging geometrically; it is the index-zero Trailmoment cut at 0 (Definition 6.1). For the second identity, $\int_0^\infty y^{s-1}\mathsf{g}^n\, dy = \Gamma(s)^2 p_n(s)$ at every real $s > 0$, and the terms of h are positive, so by monotone convergence

$$\int_0^\infty y^{s-1}\mathsf{g}^n\mathsf{h}\, dy = \sum_{k\geq 0} \frac{\Gamma(s+k)^2}{k!^2}\, p_n(s+k) = \sum_{k\geq 0} W_s(s+k)\, p_n(s+k) = \sum_{m\geq 1} W_s(m)\, p_n(m),$$

since $\Gamma(s+k)/k! = (k+1)\cdots(k+s-1)$ and W_s vanishes at $1, \dots, s-1$.

(iii) The share integral of (i) is symmetric in the $n+1$ shares, the fibre integral not depending on the coordinates in which it is written (Definition 4.1), and $\sum_e a_e = s$ on the fibre; so for each e, $\int a_e \prod_{e'} \Gamma(a_{e'})^2 = \frac{s}{n+1}\Gamma(s)^2 p_{n+1}(s)$. For e the last mark, $a_e = s - d$ in the coordinates of (i), and at $s = 1$ the closing of (ii), with $G(d) = (1-d)p_n(d)$, gives

$$\frac{1}{n+1}\, p_{n+1}(1) = -\sum_{m\geq 1} \big((1-d)p_n(d)\big)'\big|_{d=m} = \sum_{m\geq 1} \big(p_n(m) - (m-1)\, \tilde p_n(m)\big).$$

With $p_{n+1}(1) = (\mathsf{T}_{0;(1)}[x]\,\tilde{p}_n\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ from (ii) this is the stated relation. □

The following bounds give the Mellin reads of the products of g and h the hypotheses of Lemma S27 and fix their growth along the integers.

Lemma S28. *(i)* $\mathsf{g} > 0$ *and* $\mathsf{h} \geq 1$ *on* $(0,\infty)$*, and for* $y \geq 1$

$$\frac{1}{2e}\,y^{-1/2}e^{-2\sqrt{y}} \leq \mathsf{g}(y) \leq \sqrt{\pi}\,y^{-1/4}e^{-2\sqrt{y}}, \qquad e^{-4}y^{-1}e^{2\sqrt{y}} \leq \mathsf{h}(y) \leq e^{2\sqrt{y}}.$$

(ii) For integers $0 \leq j < n/2$*, every* $\vartheta^a\big(\mathsf{g}^{n-j}\mathsf{h}^j\big)$ *is* $O\big((1+|\log y|)^n\big)$ *as* $y \to 0$ *and* $O\big(y^C e^{-2(n-2j)\sqrt{y}}\big)$ *as* $y \to \infty$*. For integers* $n/2 \leq j \leq n$*,* $\int_1^\infty y^{s-1}\mathsf{g}^{n-j}\mathsf{h}^j\,dy = \infty$ *for real* $s \geq n$*.*

(iii) For these j*,* $\lim_{k\to\infty}\Big(\Gamma(k)^{-2}\int_0^\infty y^{k-1}\mathsf{g}^{n-j}\mathsf{h}^j\,dy\Big)^{1/k} = (n-2j)^{-2}$ *along the integers.*

Proof. (i) g is the integral of a positive function and $\mathsf{h} \geq 1$ term by term. The upper bound on g is Lemma 20.29(ii) at $\nu = 0$. For the lower bound restrict the integral to $x = \sqrt{y} + \tau$, $0 \leq \tau \leq 1$, where $x + y/x = 2\sqrt{y} + \tau^2/(\sqrt{y}+\tau) \leq 2\sqrt{y}+1$ and $x^{-1} \geq (2\sqrt{y})^{-1}$. For h, $\sum_m y^m/m!^2 \leq \big(\sum_m y^{m/2}/m!\big)^2 = e^{2\sqrt{y}}$; and with $m = \lfloor\sqrt{y}\rfloor \geq 1$ and $m! \leq e\,m^{m+1}e^{-m}$ (from $\log m! \leq \int_1^m \log x\,dx + \log m$),

$$\mathsf{h}(y) \geq \frac{y^m}{m!^2} \geq \frac{e^{2m}}{e^2 m^2}\Big(\frac{\sqrt{y}}{m}\Big)^{2m} \geq \frac{e^{2\sqrt{y}-2}}{e^2\,y}.$$

(ii) By the ladder, $\vartheta\mathsf{g} = -y\,\mathsf{G}_{-1;(1,-1)}(1,y)$, at most $\sqrt{\pi}e^{1/4}y^{1/4}e^{-2\sqrt{y}}$ for $y \geq 1$ by Lemma 20.29(ii) at $\nu = -1$; and $0 \leq \vartheta\mathsf{h} = \sum_m m y^m/m!^2 \leq y\,\mathsf{h}$. Since $\vartheta^2 = y$ on both, every $\vartheta^a\mathsf{g}$ and $\vartheta^a\mathsf{h}$ is a combination of the function and its ϑ with polynomial coefficients, of size $O(y^C e^{\mp 2\sqrt{y}})$ at infinity; near 0, $\mathsf{g} = -\mathsf{h}\log y + \tilde{\mathsf{g}}$ with h and $\tilde{\mathsf{g}}$ entire, so every $\vartheta^a\mathsf{g}$ is $O(1+|\log y|)$ and every $\vartheta^a\mathsf{h}$ bounded. By the Leibniz rule $\vartheta^a(\mathsf{g}^{n-j}\mathsf{h}^j)$ is a sum of products of $n-j$ derivatives of g and j of h, which gives the bounds, $e^{-2(n-j)\sqrt{y}}e^{2j\sqrt{y}} = e^{-2(n-2j)\sqrt{y}}$. For $n/2 \leq j \leq n$, (i) gives on $[1,\infty)$

$$\mathsf{g}^{n-j}\mathsf{h}^j \geq (2e)^{-(n-j)}e^{-4j}\,y^{-(n+j)/2}\,e^{2(2j-n)\sqrt{y}} \geq (2e)^{-n}e^{-4n}\,y^{-n},$$

and $\int_1^\infty y^{s-1-n}\,dy = \infty$ for $s \geq n$.

(iii) Put $b = n-2j \geq 1$ and $I(k) = \int_0^\infty y^{k-1}\mathsf{g}^{n-j}\mathsf{h}^j\,dy$. The part over $(0,1]$ is at most $\int_0^1 C(1+|\log y|)^n\,dy$, bounded in $k \geq 1$. By (i), on $[1,\infty)$ the integrand lies between $c_1 y^{k-1-n}e^{-2b\sqrt{y}}$ and $c_2 y^{k-1}e^{-2b\sqrt{y}}$ with $c_1, c_2 > 0$, and for a fixed real a, with $y = \tau^2$,

$$\int_1^\infty y^{k-1+a}e^{-2b\sqrt{y}}\,dy = 2\int_1^\infty \tau^{2k+2a-1}e^{-2b\tau}\,d\tau = 2\,\Gamma(2k+2a)\,(2b)^{-2k-2a} + O(1).$$

$\Gamma(2k+2a)/\Gamma(2k)$ has root rate one and $\Gamma(2k)(2b)^{-2k}$ grows faster than every exponential, so $\big(I(k)/\Gamma(2k)\big)^{1/k} \to (2b)^{-2}$; and $\Gamma(2k)/\Gamma(k)^2 = \frac{k}{2}\binom{2k}{k}$ has the root rate 4, so $\big(I(k)/\Gamma(k)^2\big)^{1/k} \to 4(2b)^{-2} = b^{-2}$. □

Theorem 42.12 (The law of the values of $\binom{\mathcal{E}}{1}$). *As stated.*

Proof. (i) *Annihilation.* Let $u \in \mathcal{V}$ and $v = \vartheta u$, so that $\vartheta v = yu$. For $0 \le i \le n$, $\mathbf{R}_i(u^n) = \frac{n!}{(n-i)!} u^{n-i} v^i$: this holds at $i = 0, 1$, and $\vartheta(u^{n-i}v^i) = (n-i)u^{n-i-1}v^{i+1} + i\,y\,u^{n-i+1}v^{i-1}$ gives

$$\vartheta \mathbf{R}_i(u^n) = \frac{n!}{(n-i-1)!} u^{n-i-1}v^{i+1} + i(n+1-i)\,y\,\frac{n!}{(n-i+1)!} u^{n-i+1}v^{i-1},$$

whose last term is $i(n+1-i)\,y\,\mathbf{R}_{i-1}(u^n)$; so the recursion gives the claim at $i+1 \le n$, and at $i = n$ the first term carries the factor $n - i = 0$ and $\mathbf{R}_{n+1}(u^n) = 0$. A product of n solutions is a combination of n-th powers of solutions, $u_1 \cdots u_n = \frac{1}{2^n n!} \sum_{\epsilon \in \{\pm 1\}^n} \epsilon_1 \cdots \epsilon_n \, (\epsilon_1 u_1 + \cdots + \epsilon_n u_n)^n$, so $\mathbf{Q}_n$ annihilates every such product.

Normal form and leading terms. Since $\vartheta y = y(\vartheta + 1)$, every operator built from y and ϑ is $\sum_k y^k r_k(\vartheta)$ with polynomials r_k, uniquely: applied to y^z it gives $\sum_k y^{k+z} r_k(z)$. Write $\mathbf{R}_i = \sum_k y^k \ell_{i,k}(\vartheta)$. By induction $\ell_{i,0} = \vartheta^i$ and $\deg \ell_{i,k} \le i - 2k$: $\vartheta\, y^k \ell_{i,k}(\vartheta) = y^k(\vartheta + k)\ell_{i,k}(\vartheta)$ has degree at most $i + 1 - 2k$, and so has $y \cdot y^{k-1}\ell_{i-1,k-1}(\vartheta)$. The coefficients $\alpha_{i,k}$ of ϑ^{i-2k} in $\ell_{i,k}$ therefore satisfy $\alpha_{i+1,k} = \alpha_{i,k} - i(n+1-i)\alpha_{i-1,k-1}$, the shift by k not changing a leading coefficient, and $\sigma_i(\xi, \eta) = \sum_k \alpha_{i,k}\eta^k \xi^{i-2k}$ satisfies $\sigma_{i+1} = \xi\sigma_i - i(n+1-i)\,\eta\,\sigma_{i-1}$, $\sigma_0 = 1$, $\sigma_1 = \xi$. Let J be the matrix, indexed by $0, \ldots, n$, of the derivation Δ of the forms of degree n in U, V with $\Delta U = V$ and $\Delta V = \eta U$, in the basis $w_i = U^{n-i}V^i$: $\Delta w_i = (n-i)w_{i+1} + i\eta\, w_{i-1}$. The leading principal minors of $\xi - J$, expanded along their last row, satisfy the same recursion, $\det_{i+1} = \xi \det_i - (n+1-i)\, i\eta \det_{i-1}$, so $\sigma_{n+1} = \det(\xi - J)$. Over $\mathbb{C}(\eta^{1/2})$ the forms $E_\pm = V \pm \eta^{1/2} U$ have $\Delta E_\pm = \pm\eta^{1/2} E_\pm$, so the basis $E_+^{n-j}E_-^j$ diagonalizes Δ with the eigenvalues $(n-2j)\eta^{1/2}$, and $\det(\xi - J) = \prod_{j=0}^n \big(\xi - (n-2j)\eta^{1/2}\big)$; the factors j and $n - j$ pair into $\xi^2 - (n-2j)^2\eta$, and at even n the factor $j = n/2$ is ξ. With $q_{n,k} = \ell_{n+1,k}$ and $a_{n,k} = \alpha_{n+1,k}$ this is the display; $a_{n,h}$ is the coefficient of the top power η^h, $\prod_{0 \le j < n/2} \big(-(n-2j)^2\big) \ne 0$.

The adjoint. Expanding the recursion, $\mathbf{R}_m$ is the sum over the tilings of $\{1, \ldots, m\}$ by monomers $\{a\}$ and dimers $\{a, a+1\}$ of the products of ϑ for each monomer and $-a(n+1-a)\,y$ for each dimer, taken from left to right in decreasing order of position: the tilings of $\{1, \ldots, m+1\}$ end with the monomer $\{m+1\}$ or the dimer $\{m, m+1\}$, which are the two terms of the recursion. The formal adjoint for dy/y reverses products, takes ϑ to $-\vartheta$ and keeps y; a tiling of $\{1, \ldots, m\}$ with d dimers has $m - 2d$ monomers, so $\mathbf{R}_m^*$ is $(-1)^m$ times the same sum with the products taken in increasing order of position. The reflection $a \mapsto m + 1 - a$ of the positions maps tilings to tilings, reverses the order, and takes the dimer $\{a, a+1\}$ to $\{a', a'+1\}$ with $a' = m - a$, of weight $-(m - a')(n + 1 - m + a')\,y$. At $m = n + 1$ this weight is $-a'(n + 1 - a')\,y$, so $\mathbf{Q}_n^* = \mathbf{R}_{n+1}^* = (-1)^{n+1}\mathbf{R}_{n+1}$. Since $q(-\vartheta)\,y^k = y^k q(-\vartheta - k)$, $\mathbf{Q}_n^* = \sum_k q_{n,k}(-\vartheta)y^k = \sum_k y^k q_{n,k}(-\vartheta - k)$, and the uniqueness of the normal form gives $q_{n,k}(-\vartheta - k) = (-1)^{n+1} q_{n,k}(\vartheta)$.

(ii) For $k \ge 1$, $c_{n,k}$ has degree at most $(n + 1 - 2k) + 2(k-1) = n - 1$ with the coefficient $(-1)^{n+1}a_{n,k}$ of s^{n-1}, as $c_{n,0} = (-1)^{n+1}s^{n-1}$ has with $a_{n,0} = 1$. Setting $\xi = 1$ in (i), $\sum_k a_{n,k}\lambda^k = \prod_{0 \le j < n/2} \big(1 - (n-2j)^2\lambda\big)$, whose coefficients $(-1)^k e_k\big((n-2j)^2\big)$ are nonzero for $0 \le k \le h$; so every $c_{n,k}$ has degree $n-1$ and the symbol is χ_n. By (i), $c_{n,k}(-s-k) = q_{n,k}(s)\big((-s-k+1)\cdots(-s-1)\big)^2 = (-1)^{n+1} q_{n,k}(-s-k)\big((s+1)\cdots(s+k-1)\big)^2 = (-1)^{n+1} c_{n,k}(s)$ for $k \ge 1$, and $c_{n,0}(-s) = s^{n-1} = (-1)^{n+1} c_{n,0}(s)$. The double zeros are those of the squared factor. For odd n, $q_{n,h}$ is the nonzero constant $a_{n,h}$; for even n it has degree one, $q_{n,h}(\vartheta) = a_{n,h}(\vartheta - \vartheta_0)$, and $q_{n,h}(-\vartheta - h) = -q_{n,h}(\vartheta)$ forces $\vartheta_0 = -h/2$, so $q_{n,h}(-s-h) = -a_{n,h}(s + h/2)$; in both cases $c_{n,h}(s) \ne 0$ at the integers $s \ge 0$. For $n \ge 2$ let $M(s) = \Gamma(s)^2 P_{\binom{\varepsilon}{1}}(s\mathbf{1}; s, s) = \int_0^\infty y^{s-1}\mathrm{g}^n\, dy$ (Section 42.6). By Lemma S28(ii), Lemma S27(i) applies to g^n, and $\mathbf{Q}_n(\mathrm{g}^n) = 0$ gives $\sum_k q_{n,k}(-s-k)\, M(s+k) = 0$ on $\operatorname{Re} s > 0$. Dividing by $\Gamma(s+1)^2$, with $\Gamma(s)^2/\Gamma(s+1)^2 = s^{-2}$ and $\Gamma(s+k)^2/\Gamma(s+1)^2 = \big((s+1)\cdots(s+k-1)\big)^2$, and $q_{n,0}(-s) = (-s)^{n+1}$, gives the identity on $\operatorname{Re} s > 0$, and on $\mathbb{C}$ by the meromorphic continuation (Proposition 39.34).

(iii) Write $P(k) = P_{\binom{\varepsilon}{1}}(k\mathbf{1}; k, k)$ and suppose $\sum_{i=0}^{m} r_i(k)P(k+i) = 0$ for all large integers k, with $r_i \in \mathbb{C}[k]$, $r_0 r_m \neq 0$ and $m < h$. The centre ray at the strength one has origin 0, letter exponents one and walls $\kappa_{1,S} = 1$, so by Proposition 42.2(i) the relation holds identically. On $\operatorname{Re} s > 0$ multiply it by $\Gamma(s+m)^2$: $\sum_i \tilde{r}_i(s)M(s+i) = 0$ with the polynomials $\tilde{r}_i(s) = r_i(s)\big((s+i)\cdots(s+m-1)\big)^2$, $\tilde{r}_m = r_m$. Put $T = \sum_i y^i \tilde{r}_i(-\vartheta - i)$. By Lemma S27(i), with Lemma S28(ii), the Mellin read of $T(\mathsf{g}^n)$ is $\sum_i \tilde{r}_i(s)M(s+i) = 0$, and by Lemma S27(ii) $T(\mathsf{g}^n) = 0$.

On the ring of polynomials in an indeterminate L with entire coefficients let ϑ act by $\vartheta\big(\sum_l E_l L^l\big) = \sum_l (\vartheta E_l)L^l + \sum_l l E_l L^{l-1}$, and put $\Phi(y, L) = T\big[(\tilde{\mathsf{g}} - \mathsf{h}\, L)^n\big] = \sum_{l \le n} E_l(y) L^l$, E_l entire. Substituting $L = \log y - c$, for a constant c, commutes with this ϑ, so $T\big[(\mathsf{g} + c\,\mathsf{h})^n\big] = \Phi(y, \log y - c)$ on $(0, \infty)$, and $\Phi(y, \log y) = T(\mathsf{g}^n) = 0$. The function $y \mapsto \Phi(y, \log y)$ continues along every path in $\mathbb{C}^\times$, and once around 0 it becomes $\Phi(y, \log y + 2\pi i)$; the continuation of 0 is 0, so $\Phi(y, \log y + 2\pi i\ell) = 0$ for every $\ell \in \mathbb{Z}$ and $y > 0$. For fixed y the polynomial $L \mapsto \Phi(y, L)$ then has infinitely many zeros, so $\Phi = 0$, and $T\big[(\mathsf{g} + c\mathsf{h})^n\big] = 0$ for every $c \in \mathbb{C}$; the coefficients of the powers of c give $T\big(\mathsf{g}^{n-j}\mathsf{h}^j\big) = 0$ for $0 \le j \le n$.

For $0 \le j < n/2$ let $I_j(k) = \int_0^\infty y^{k-1} \mathsf{g}^{n-j}\mathsf{h}^j\, dy$. Lemma S27(i) for $\mathsf{g}^{n-j}\mathsf{h}^j$ (Lemma S28(ii)) gives $\sum_i \tilde{r}_i(k) I_j(k+i) = 0$ for the integers $k \ge 1$. Take k_1 beyond the zeros of r_m; on the integers $k \ge k_1$ a solution of this recurrence of order m is fixed by its first m values, so the $h > m$ sequences $(I_j(k))_{k \ge k_1}$ are linearly dependent. They are not: if $\sum_j b_j I_j(k) = 0$ for $k \ge k_1$ with some $b_j \neq 0$, let j_0 be the largest such j; by Lemma S28(iii), $I_j(k)/\Gamma(k)^2$ has the exact root rate $(n-2j)^{-2}$, largest at j_0, so $|b_{j_0}| I_{j_0}(k) > \sum_{j<j_0} |b_j| I_j(k)$ for large k, a contradiction. So the tier is at least h, and the recurrence of (ii) has the order h and $c_{n,0}c_{n,h} \neq 0$.

By Proposition 42.2(i) the closings, here the constant terms of $(\sum_e \alpha_e)^j (\sum_e \alpha_e^{-1})^j$ (Corollary 39.36), that is $\sum_{|v|=j} \binom{j}{v}^2$, satisfy the reflected recurrence for every $j \in \mathbb{N}$, and by Corollary 39.60 they satisfy no recurrence that the values do not satisfy, read at k and at $-j$; so none of order less than h. In the value module, a relation $\sum_{i<h} r_i(k)\,\mathrm{Sh}^i[1] \in \mathrm{Ann}(\langle\cdot\rangle)$ with rational r_i not all zero would be a recurrence of order less than h for the values, so the classes of $\mathrm{Sh}^i[1]$, $0 \le i < h$, are independent there; the element $\sum_{i=0}^{h} c_{n,i}(k)\,\mathrm{Sh}^i[1]$, k the strength, has vanishing values and lies in $\mathrm{Ann}(\langle\cdot\rangle)$, a submodule (Theorem 39.4(ii)), and with $c_{n,0}c_{n,h} \neq 0$ it expresses $\mathrm{Sh}^h[1]$ and $\mathrm{Sh}^{-1}[1]$ through these classes; so their span is the cyclic submodule of [1] in the value module, of dimension h. □

Proposition 42.13 (A mark added carries the law of the values). *As stated.*

Proof. (i) For a fixed solution u both sides are linear differential operators in F of order $n+2$, with coefficients analytic on $(0, \infty)$. By Theorem 42.12(i), $\mathbf{Q}_{n+1} = \vartheta^{n+2} + \sum_{k \ge 1} y^k q_{n+1,k}(\vartheta)$ with $\deg q_{n+1,k} \le n$, so $\mathbf{Q}_{n+1}(uF) = u\,\vartheta^{n+2}F + (n+2)(\vartheta u)\,\vartheta^{n+1}F + (\text{order} \le n)$; and $\mathbf{Q}_n = \vartheta^{n+1} + \sum_{k \ge 1} y^k q_{n,k}(\vartheta)$ with $\deg q_{n,k} \le n-1$, so the right side is $u\,\vartheta^{n+2}F + (n+2)(\vartheta u)\,\vartheta^{n+1}F + (\text{order} \le n)$. Their difference is an operator of order at most n that annihilates every F in the space spanned by the products of n solutions, of dimension $n+1$: the right side vanishes there by Theorem 42.12(i), and the left side because uF is a product of $n+1$ solutions. An operator of order at most n whose highest nonzero coefficient does not vanish on an interval has there a space of solutions of dimension at most n, and the $n+1$ analytic functions stay independent on every interval; so the difference is 0.

(ii) Apply (i) with $u = \mathsf{h}$ to $F = y^z$, $z \in \mathbb{C}$, using $\vartheta^a y^w = w^a y^w$ and $\vartheta\mathsf{h} = \sum_m m\, y^m/m!^2$. Both sides are y^z times entire functions of y, and comparing the coefficients of y^{z+N},

$$\sum_{k+m=N} \frac{q_{n+1,k}(z+m)}{m!^2} = \sum_{j+m=N} \frac{\big(z + j + (n+2)m\big)\, q_{n,j}(z)}{m!^2} \qquad (N \in \mathbb{N},\ z \in \mathbb{C}).$$

By Theorem 42.12(i), $q_{n+1,k}(z+m) = (-1)^n q_{n+1,k}(-z-N)$ when $k+m=N$ and $q_{n,j}(z) = (-1)^{n+1} q_{n,j}(w+m)$ with $w=-z-N$ when $j+m=N$; and $z+j+(n+2)m = (n+1)m-w$. So

$$\sum_{k+m=N} \frac{q_{n+1,k}(w)}{m!^2} = \sum_{j+m=N} \frac{\big(w-(n+1)m\big)\, q_{n,j}(w+m)}{m!^2},$$

and applying the same symmetry once more, $q_{n+1,k}(w) = (-1)^n q_{n+1,k}(-w-k)$ and $q_{n,j}(w+m) = (-1)^{n+1} q_{n,j}(-w-N)$,

$$\sum_{k+m=N} \frac{q_{n+1,k}(-s-k)}{m!^2} = \sum_{j+m=N} \frac{\big((n+1)m-s\big)\, q_{n,j}(-s-N)}{m!^2} \qquad (s=w).$$

Multiply by $\Gamma(s+N)^2/\Gamma(s+1)^2$ and put $x=s+N$. By the definitions, $c_{n+1,k}(s) = q_{n+1,k}(-s-k)\,\Gamma(s+k)^2/\Gamma(s+1)^2$ for every $k\ge 0$, so the left side becomes $\sum_k c_{n+1,k}(s)\,\Gamma(x)^2/\big(\Gamma(s+k)^2\Gamma(x-s-k+1)^2\big) = \sum_k c_{n+1,k}(s)\binom{x-1}{s+k-1}^2$. With $c_{n,j}(x-j) = q_{n,j}(-x)\,\Gamma(x)^2/\Gamma(x-j+1)^2$, $(n+1)m-s = (n+1)(x-j)-(n+2)s$ and $A_s(x-j) = \big((n+1)(x-j)-(n+2)s\big)\Gamma(x-j+1)^2/\big(\Gamma(s+1)^2\Gamma(x-j-s+1)^2\big)$, the right side becomes $\sum_j c_{n,j}(x-j)A_s(x-j)$. After division by $\binom{x}{s}^2$ both sides are rational functions of (x,s), each binomial quotient being a quotient of rising factorials, and they agree on the lines $x-s=N$, $N\in\mathbb{N}$; a polynomial in (x,s) vanishing on infinitely many of these lines is divisible by infinitely many distinct factors $x-s-N$, so it is zero, and the identity holds. At integers $s,x\ge 1$, $W_{s+k}(x)/\Gamma(s+k)^2 = \prod_{l=1}^{s+k-1}(x-l)^2/(s+k-1)!^2 = \binom{x-1}{s+k-1}^2$, both sides vanishing for $x<s+k$; the right side is $(L_n^* A_s)(x)$ for the recurrence L_n with the coefficients $c_{n,j}$ (Definition 42.1), and $\binom{x}{s} = x(x-1)\cdots(x-s+1)/s!$ vanishes at $x=0,1,\dots,s-1$. □

Proposition 42.14 (The lowered settings). *As stated.*

Proof. (i) By Theorem 42.12(i), $\mathbf{Q}_n(\mathsf{g}^{n-j}\mathsf{h}^j)=0$; Lemma S27(i), which applies by Lemma S28(ii), gives $\sum_k q_{n,k}(-s-k)\,\Gamma(s+k)^2\xi_{n,j}(s+k) = 0$ on $\operatorname{Re} s>0$, and the division of the proof of Theorem 42.12(ii) gives the recurrence. For $j=0$ the display of Section 42.6 gives $\xi_{n,0}(s) = P_{\binom{\varepsilon}{1}}(s\mathbf{1}; s, s)$.

(ii) On $(0,1]$, $0<\mathsf{g}^{n-j}\mathsf{h}^j \le C(1+|\log y|)^{n-j}$ by Lemma S28(ii) and $\mathsf{g} = -\mathsf{h}\log y + \tilde{\mathsf{g}}$, so for real $s\in(0,1]$, $\int_0^\infty y^{s-1}\mathsf{g}^{n-j}\mathsf{h}^j\,dy \le C\int_0^1 y^{s-1}(1+|\log y|)^{n-j}dy + C' = O(s^{-(n-j+1)})$, and with $\Gamma(s)^{-2} = O(s^2)$, $s^{n-1}\xi_{n,j}(s) = O(s^j)\to 0$ for $j\ge 1$. In the recurrence on $(0,\infty)$ the term $c_{n,0}(s)\xi_{n,j}(s) = (-1)^{n+1}s^{n-1}\xi_{n,j}(s)$ then tends to 0 as $s\downarrow 0$, while the others tend to $c_{n,k}(0)\xi_{n,j}(k)$, $\xi_{n,j}$ being continuous on $\operatorname{Re} s>0$; so $\sum_{k\ge 1} c_{n,k}(0)\xi_{n,j}(k) = 0$. For $j=0$, $s^{n-1}\xi_{n,0}(s)\to V_1 = n!$ by Proposition 39.34, the walls of the direction being $\kappa_{1,S} = c(S) = 1$ for every nonempty proper S, so that $V_1 = \sum_\pi 1 = n!$; and the same limit gives $\sum_{k\ge 1} c_{n,k}(0)\xi_{n,0}(k) = -(-1)^{n+1}n!$.

(iii) By Lemma S28(iii), $\xi_{n,j}$ has the root rate $\lambda = (n-2j)^{-2}$ along the integers. The recurrence has $c_{n,0}(k)c_{n,h}(k)\ne 0$ at the integers $k\ge 1$, every $c_{n,k}$ of degree $n-1$, and the roots $(n-2j')^{-2}$, $0\le j'<n/2$, of its symbol are positive and distinct (Theorem 42.12(ii)); so the proof of Proposition 42.7(i), which uses only these properties, gives $\xi_{n,j}(k+1)/\xi_{n,j}(k)\to\lambda_c$ for a root λ_c of modulus λ, that is $\lambda_c = (n-2j)^{-2}$.

(iv) $c_{n,h}(k)\ne 0$ at the integers $k\ge 1$ (Theorem 42.12(ii)), so a solution on these integers is fixed by its first h values, and the solutions form a space of dimension h. The h sequences are solutions by (i) and are independent by (iii), as in the proof of Theorem 42.12(iii): in a vanishing combination the term with the largest j would dominate. So they are a basis. The linear form $x\mapsto\sum_{k=1}^h c_{n,k}(0)x(k)$ is $(-1)^n n!$ on $\xi_{n,0}$ and 0 on the others by (ii), which gives the last assertion. □

Corollary 42.15 (The value span of $\binom{\mathcal{E}}{1}$). *As stated.*

Proof. (i) The first relation is Proposition 42.14(ii) at $j=0$. The recursion of Theorem 42.12 has integer coefficients, so every $q_{n,k}$ and every $c_{n,k}$ has integer coefficients. $c_{n,h}(0)\neq 0$, so the first relation gives $p_n(h)\in\mathbb{Q}+\sum_{i<h}\mathbb{Q}\,p_n(i)$, and for $k>h$ the recurrence of Theorem 42.12(ii) at $s=k-h\geq 1$, with $c_{n,h}(k-h)\neq 0$, writes $p_n(k)$ through $p_n(k-h),\dots,p_n(k-1)$; by induction every $p_n(k)$ lies in $\mathbb{Q}+\sum_{i=1}^{h-1}\mathbb{Q}\,p_n(i)$. The values of the centre ray at the strength σ are $p_n(k\sigma)$ (Definition 38.13).

(ii) For even n every $n-2j$, $0\leq j<n/2$, is at least 2, so $\chi_n(1)=(-1)^{n+1}\prod_j\big(1-(n-2j)^2\big)\neq 0$. The values of the centre ray have the root rate $n^{-2}<1$ and the slopes at most n^{-2} (Proposition 42.2(iii), $f(\alpha^\star)=f(\mathbf{1})=n^{-2}$). Every $c_{n,k}$ with $k>j\geq 1$ has a double zero at $-j$ (Theorem 42.12(ii)), so by Proposition 42.3 the only boundary numbers are $\beta_0(0)$ and $\beta_0'(0)$ of $\beta_0=c_{n,0}\,p_n=(-1)^{n+1}s^{n-1}p_n$: by Proposition 42.6, $\beta_0(0)=(-1)^{n+1}V_1=(-1)^{n+1}n!$, and $\beta_0'(0)=(-1)^{n+1}\mathsf{L}_1=0$, the list having unit weights. Proposition 42.4(ii) with $\Bbbk=\mathbb{Q}$ and $D=n-1$ gives the claim. The two last numbers are such Trailmoments by Proposition 42.11(ii), with the rational polynomials W_s and W_s'. □

Corollary 42.16 (The exact pairing of $\binom{\mathcal{E}}{1}$). *As stated.*

Proof. The centre ray of $\binom{\mathcal{E}}{1}$ at the strength one satisfies the hypotheses of Proposition 42.2, and the recurrence of Theorem 42.12(ii) holds for its values with $c_{n,k}(-s-k)=(-1)^{n+1}c_{n,k}(s)$; its closings are the C_l of the statement (proof of Theorem 42.12(iii)). Proposition 42.8(ii), with $\gamma_{n-1}=(-1)^{n+1}$ and $V_1=n!$, gives the first display. Every $c_{n,k}$ has degree $n-1$, so Proposition 42.8(iii) applies: the roots of χ_n are the simple roots $(n-2j)^{-2}$, $0\leq j<n/2$, with $\lambda_\star=f(\mathbf{1})=n^{-2}$ at $j=0$, and $1-(n-2j)^2/n^2=4j(n-j)/n^2$. The Hessian H of Theorem 38.15 at the centre is $2\big(\kappa_{\mathbf{1}}(X_e,X_{e'})\big)_{e,e'\neq e_0}$, which is the Hessian of Proposition 42.9(ii) at the sign $\mathbf{1}$ and $\sigma=1$, of determinant $2^{n-1}/n^n$. As a check, the two sides agree directly: for $n=2l+1$, $h-1=l$ and $\prod_{j=1}^{l}j(n-j)=l!\,(2l)!/l!=(n-1)!$, and for $n=2l+2$, $h-1=l$ and $\prod_{j=1}^{l}j(n-j)=l!\,(2l+1)!/(l+1)!=2(n-1)!/n$; in both cases $\prod_{j=1}^{h-1}4j(n-j)/n^2=2^{n-1}(n-1)!/n^{n-1}=n!\,2^{n-1}/n^n$. □

Proposition 42.17 (The power of one mark as a mixture). *As stated.*

Proof. Write $p_n(s)=P_{\binom{\mathcal{E}}{1}}(s\mathbf{1};s,s)$ for $|\mathcal{E}|=n$. By Theorem 38.14(i), $0<f_n\leq f_n(\mathbf{1})=n^{-2}$ on the chart, so μ_{f_n} is carried by $(0,n^{-2}]$, and $\int t^s\mu_{f_n}(dt)=\int_{y_{e_0}=0}f_n^s\,dy=p_n(s)$ for $\operatorname{Re}s>0$, the image of a measure under a map (Definition 1.1(vi)); the same holds at $n+1$ marks. The measure μ_{f_n} has infinite mass near 0, and every moment of positive order is finite. By Fubini's theorem and $y=ty'$, $\int_0^\infty y^{s-1}\mathsf{g}(y/t)\,dy=t^s\int_0^\infty y'^{s-1}\mathsf{g}(y')\,dy'=t^s\Gamma(s)^2$, the last because $\int_0^\infty y^{s-1}e^{-y/x}dy=\Gamma(s)x^s$ and $\int_0^\infty x^{s-1}e^{-x}dx=\Gamma(s)$.

(i) Put $G(y)=\int\mathsf{g}(y/t)\,\mu_{f_n}(dt)$. For real $s>0$, by Tonelli's theorem $\int_0^\infty y^{s-1}G(y)\,dy=\Gamma(s)^2\int t^s\mu_{f_n}(dt)=\Gamma(s)^2p_n(s)$, finite, which is $\int_0^\infty y^{s-1}\mathsf{g}^n\,dy$ by the display of Section 42.6. So G is finite almost everywhere; since g is decreasing ($\partial_y\mathsf{g}=-\mathsf{G}_{-1;(1,-1)}(1,y)<0$), $\mathsf{g}(y/t)\leq\mathsf{g}(y_0/t)$ for $y\geq y_0$, and dominated convergence makes G finite and continuous on $(0,\infty)$. For $s=c+i\tau$ the same Fubini argument applies, so the integrable functions $e^{cv}G(e^v)$ and $e^{cv}\mathsf{g}(e^v)^n$ have the same Fourier transform; they are equal, by the uniqueness of the Fourier transform on $L^1(\mathbb{R})$ as in Lemma S27(ii), and both being continuous, $G=\mathsf{g}^n$.

(ii) The table on $\{1,2\}$ with the bases $\{1\}$ and $\{2\}$ is the table of Corollary 18.24 on two marks, the basis $\{2\}=\{1,2\}-1$ carrying $\theta_1=1$ and $\{1\}$ carrying $\theta_2=t^{-1/2}$; its letters are $K=\alpha_2+t^{-1/2}\alpha_1$ and $\Psi=\alpha_1+t^{-1/2}\alpha_2$, and its centre stride on the chart $\alpha_1=1$, $\alpha_2=x$, is

$\alpha_1\alpha_2/(K\Psi) = x/\big((x+t^{-1/2})(1+t^{-1/2}x)\big) = \phi_t(x)$, and $dy = dx/x$ on that chart. So $\int u^s \mu_{\phi_t}(du) = P(s\mathbf{1}; s, s)$ for that table, and Corollary 18.24 at $\mathbf{m} = s\mathbf{1}$, $\nu_e = 0$, gives $\Gamma(s)^2 \int u^s \mu_{\phi_t}(du) = \int_0^\infty y^{s-1} \mathsf{g}(y)\, \mathsf{g}(\theta_2^2 y)\, dy = \int_0^\infty y^{s-1} \mathsf{g}(y)\, \mathsf{g}(y/t)\, dy$. By (i) and Tonelli's theorem, for real $s > 0$,

$$\begin{aligned}\Gamma(s)^2 \int u^s \mu_{f_{n+1}}(du) &= \int_0^\infty y^{s-1} \mathsf{g}(y)\, \mathsf{g}(y)^n\, dy = \int \mu_{f_n}(dt) \int_0^\infty y^{s-1} \mathsf{g}(y)\, \mathsf{g}(y/t)\, dy \\ &= \Gamma(s)^2 \int \mu_{f_n}(dt) \int u^s \mu_{\phi_t}(du),\end{aligned}$$

and by Fubini's theorem the same holds on $\operatorname{Re} s > 0$. The measures $\mu_{f_{n+1}}$ and $\int \mu_{\phi_t}\, \mu_{f_n}(dt)$ therefore have the same moments $\int u^s(\cdot)$ on the line $\operatorname{Re} s = c > 0$; their images under $u \mapsto v = \log u$, weighted by e^{cv}, are finite measures on $\mathbb{R}$ with the same Fourier transform, hence equal, and so are the two measures. □

Proposition 42.18 (Balanced directions of $\binom{\mathcal{E}}{1}$). *As stated.*

Proof. The walls of $\binom{\mathcal{E}}{1}$ at $(\mathbf{m}; s, t)$ are $\kappa_S = m_S - t(|S| - 1)$, every proper S meeting a basis $\{e\}$ in at most one mark and the cobases $\mathcal{E} - e$ in at least $|S| - 1$, so the hypothesis says that every proper wall is positive, at $(k\mathbf{m}; ks, kt)$ as well. The display of Section 42.6 at these data, from Corollary 18.24 for the dual table at the exponents (kt, ks) and Proposition 8.15, gives $\Gamma(sk)\Gamma(tk)P(k) = \int_0^\infty y^{tk-1} \prod_e \mathsf{G}_{c_e k;(1,-1)}(1, y)\, dy$. By the torus homogeneity (Theorem 2.4(iii)) at $\lambda = y^{1/2}$, $\mathsf{G}_{\nu;(1,-1)}(\lambda, \lambda^{-1}y) = \lambda^{-\nu}\mathsf{G}_{\nu;(1,-1)}(1, y)$, that is $\mathsf{G}_{\nu;(1,-1)}(1, y) = y^{\nu/2}\, \mathsf{G}_{\nu;(1,-1)}(\sqrt{y}, \sqrt{y})$; the product of the powers is $y^{k\sum_e c_e/2} = y^{(s-t)k/2}$, and $tk - 1 + \frac{(s-t)k}{2} = \frac{(s+t)k}{2} - 1$. The reflection of Proposition 2.3 gives $\mathsf{G}_{\nu;(1,-1)}(a, b) = \mathsf{G}_{-\nu;(-1,1)}(a, b) = \mathsf{G}_{-\nu;(1,-1)}(b, a)$, so at equal coefficients the Gramma of one mark is even in its index, and the integral depends only on $s + t$ and the multiset $\{|c_e|\}$. Two directions with the same $s + t$ and multiset therefore have $\Gamma(sk)\Gamma(tk)P(k) = \Gamma(s'k)\Gamma(t'k)P'(k)$, which is the stated quotient of Beta corners, a quotient of factorials at integer k. The image of the integrand $\alpha^{k\mathbf{m}} K^{-ks} \Psi^{-kt}$ under $\alpha \mapsto \alpha^{-1}$, with $K(\alpha^{-1}) = \alpha^{-\mathcal{E}}\Psi(\alpha)$ and $\Psi(\alpha^{-1}) = \alpha^{-\mathcal{E}}K(\alpha)$, is $\alpha^{k((s+t)\mathbf{1}-\mathbf{m})} K^{-kt} \Psi^{-ks}$, the integrand at $((s + t)\mathbf{1} - \mathbf{m}; t, s)$, whose offsets are $(s + t) - m_e - s = -c_e$. □

Definition 42.19 (Hinge pairs; norms; the two-sided core; the class density). As stated.

Proof. For a parallel class $K_{\mathcal{A}\backslash g} = \sum_{e \in B} \alpha_e$ and $K_{\mathcal{A}/g} = 1$; for a series class $K_{\mathcal{A}\backslash g} = \alpha^B$ and $K_{\mathcal{A}/g} = e_{|B|-1}(\alpha_B) = \alpha^B A'$, so $\gamma = 1/A'$, $\gamma(\alpha^{-1}) = 1/A$ and $v = \alpha^B A' \cdot \alpha^{-B} A = AA'$; for $\binom{\{h,g\}}{1}$, $K_{\mathcal{A}\backslash g} = \alpha_h$ and $K_{\mathcal{A}/g} = 1$. The hinge values are homogeneous of degree one, which gives the action of the scale; on the quadruple the scale acts by $(\lambda^{r-1}c, \lambda^r d, \lambda^{1-r}c', \lambda^{-r}d')$, r the rank of $\mathcal{A}$. The letter $K_{\mathcal{H}}$ has the degree at most one in each marker, so $\prod_i c_i \cdot K_{\mathcal{H}}(\mathbf{d}/\mathbf{c}) = \mathcal{H}^{\hom}(\mathbf{c}, \mathbf{d})$ where every $c_i \neq 0$, and likewise at α^{-1}. At $x_i' = x_i^{-1}$, $\Phi_{\mathcal{H}} = K_{\mathcal{H}}(x)K_{\mathcal{H}}(x^{-1})$, the reciprocal stride of the centre ray of $\mathcal{H}$ at the strength one. On the compact torus the constant term of a Laurent polynomial is its mean, so $\int t^w \nu_s(dt) = \mathrm{CT}((AA')^w)$. □

Theorem 42.20 (A list is its core read against its cells). *As stated.*

Proof. (i) Theorem 21.4 at α and at α^{-1}: $K(\alpha) = \prod_i K_{\mathcal{A}_i/g_i}(\alpha)\, K_{\mathcal{H}}(\gamma(\alpha))$, and the product of the two prefactors is $\prod_i v_{\mathcal{A}_i}$. On the whole torus $K(\alpha) = \mathcal{H}^{\hom}(\mathbf{c}, \mathbf{d})$ at the quadruples, by Theorem 39.56(i) for the tree with the root $\mathcal{H}$ and one vertex for each cell, and likewise at α^{-1}.

(ii) On the compact torus $\alpha_e^{-1} = \bar{\alpha}_e$, so $A_i' = \bar{A}_i$ and $\mathsf{C}_j(1) = \mathbb{E}\big[\Phi_{\mathcal{H}}(A, \bar{A})^j\big]$ under the Haar probability. The totals of different classes depend on disjoint marks, so they are independent,

and each is invariant under rotations: $A_i = r_i u_i$ with u_i uniform on the circle and independent of r_i^2, whose law is ν_{s_i}. With $\bar{u}_i = u_i^{-1}$, $\mathbb{E}_u\big[K_{\mathcal{H}}(ru)^j K_{\mathcal{H}}(ru^{-1})^j\big]$ is the constant term in u, which is $\sum_w \big([x^w]K_{\mathcal{H}}^j\big)^2 \prod_i r_i^{2w_i} = \mathrm{CT}_x\big[K_{\mathcal{H}}(x)^j K_{\mathcal{H}}(r^2x^{-1})^j\big]$. Taking the mean over the r_i gives the display; the supports of the ν_{s_i} are bounded, so the series in τ^{-1} may be averaged term by term for large $|\tau|$.

(iii) (i) at the level of maps: the hinge quadruples act on disjoint sets of marks, their coordinates are Laurent polynomials, and $f^{-1} = \Phi_{\mathcal{H}}^{\mathrm{hom}}(q_{\mathcal{A}_1}, \dots, q_{\mathcal{A}_q})$ with $\Phi_{\mathcal{H}}^{\mathrm{hom}}$ a polynomial; all the maps are equivariant for the scale, f^{-1} and dy being invariant. The pencil module is the cohomology in degree 0 of the direct image of $\mathcal{O}_{X_F}$ along $\varphi = f^{-1}$, its definition being the relative de Rham complex of that direct image (Definition 39.47). The direct image along a composite is the composite of the direct images, and along a product of maps it is the external product (the Künneth formula for $\mathcal{D}$-modules); the maps are morphisms of affine varieties, so their direct images have no cohomology in positive degrees, and in the spectral sequence of the composite the only term of total degree 0 is the direct image in degree 0 of the direct image in degree 0, which no differential reaches. The letter complement is the preimage of the open set where $\Phi_{\mathcal{H}}^{\mathrm{hom}} \neq 0$, and a direct image restricted to an open set of the target is the direct image from its preimage; the scale is removed on a chart, as in the proof of Theorem 39.56(ii). The class $[dy]$ is the image of $\boxtimes_i[\prod_{e\in B_i} d\alpha_e/\alpha_e]$, which lies in $\boxtimes_i \mathcal{H}_{\mathcal{A}_i}$; so $\mathcal{D}_{\mathcal{B}}[1]$ is the image of the submodule generated by it. Characteristic cycles are additive and nonnegative along submodules and quotients, which gives the last claim. □

Corollary 42.21 (The pencil of a list along its canonical tree). *As stated.*

Proof. A list is plain, so the weights of Ψ are those of K and $K^{\Psi} = K$: the data of Theorem 39.56(i) of a vertex is the hinge quadruple of its subtree cell. The centre ray at the strength one has $\mathbf{m}_1 = \mathbf{1}$ and $s_1 = t_1 = 1$, so $p_e = 1 - 1 = 0$ and the last coordinate is 1, and the root map is $\mathcal{H}_o^{\mathrm{hom}}(\mathbf{c}, \mathbf{d})\mathcal{H}_o^{\mathrm{hom}}(\mathbf{c}', \mathbf{d}')$, which is $\Phi_{\mathcal{H}_o}^{\mathrm{hom}}$ (Definition 42.19(iii)). The nodes of the canonical hinge tree are prime nodes and the series and parallel nodes $\binom{S}{|S|-1}$ and $\binom{S}{1}$ (Theorem 23.16, Definition 23.13). For $\mathcal{H} = \binom{S}{1}$ with the hinge $g \in S$, $\mathcal{H}/g$ has the single basis $\varnothing$ and $\mathcal{H} \setminus g = \binom{S-g}{1}$, which gives (i); for $\mathcal{H} = \binom{S}{|S|-1}$, $\mathcal{H}/g = \binom{S-g}{|S|-2}$ and $\mathcal{H} \setminus g$ has the single basis $S - g$, which gives (ii); the ratios d/c are $\sum_l d_l/c_l$ and $\big(\sum_l c_l/d_l\big)^{-1}$. A parallel node of marks has $(1, \sum_e \alpha_e)$ at α and $(1, \sum_e \alpha_e^{-1})$ at α^{-1}; a series node of marks has $(e_{|B|-1}(\alpha_B), \alpha^B) = (\alpha^B A', \alpha^B)$ and the same at α^{-1}. The last statement is Theorem 39.56(iv), every vertex being a prime node or a series or parallel node of at most n marks and markers, and the lists on at most n marks being finitely many up to the names of the marks. □

Proposition 42.22 (The closings of a substitution). *As stated.*

Proof. $K_{\mathcal{H}}$ is multilinear, so $K_{\mathcal{H}}^j$ has the degree at most j in each x_i, and by Theorem 21.4

$$K(\alpha)^j = \sum_w [x^w] K_{\mathcal{H}}^j \prod_i K_{\mathcal{A}_i \setminus g_i}(\alpha)^{w_i} K_{\mathcal{A}_i/g_i}(\alpha)^{j-w_i},$$

and likewise at α^{-1} with an index w'. The constant term of a product of Laurent polynomials on disjoint sets of marks is the product of their constant terms. On B_i the factor at α is homogeneous of the degree $j(r_{\mathcal{A}_i} - 1) + w_i$ and the factor at α^{-1} of the degree $-j(r_{\mathcal{A}_i} - 1) - w_i'$, the hinge minors having the ranks $r_{\mathcal{A}_i}$ and $r_{\mathcal{A}_i} - 1$; so the constant term on B_i vanishes unless $w_i' = w_i$, and the double sum collapses to the display. The three cases are the letters of Definition 42.19: $K_{\mathcal{A}\setminus g} K_{\mathcal{A}\setminus g}^* = AA'$

and $K_{\mathcal{A}/g}K^*_{\mathcal{A}/g} = 1$ for a parallel class, 1 and AA' for a series class, and 1 and 1 for a mark left in place. For $\mathcal{A} = \mathcal{A}_0\langle\mathcal{A}' \text{ at } x\rangle$ the hinge minors are $\mathcal{A}_0 \setminus g$ and $\mathcal{A}_0/g$ with $\mathcal{A}'$ substituted at x, and Theorem 21.4 inside them gives $K^w_{\mathcal{A}\setminus g}K^{j-w}_{\mathcal{A}/g} = K^j_{\mathcal{A}'/g'}\big(K^w_{\mathcal{A}_0\setminus g}K^{j-w}_{\mathcal{A}_0/g}\big)(\alpha_{B_0-x}, \gamma_{\mathcal{A}'})$; the same expansion in the monomials α^u of the cell $\mathcal{A}_0$, with the variable of x read at the hinge value of $\mathcal{A}'$, and the same collapse give the last display. □

Lemma 42.23 (The occupations of a substitution). *As stated.*

Proof. $\log K = \sum_i \log K_{\mathcal{A}_i/g_i} + \log K_{\mathcal{H}}(\gamma)$. For $e \in B_i$, $\alpha_e\partial_e \log\gamma_i = R_e^{\mathcal{A}_i\setminus g_i} - R_e^{\mathcal{A}_i/g_i}$, and $\alpha_e\partial_e \log K_{\mathcal{H}}(\gamma) = \big(x_i\partial_{x_i}\log K_{\mathcal{H}}\big)(\gamma)\,\alpha_e\partial_e\log\gamma_i = \rho_i\,\alpha_e\partial_e\log\gamma_i$, which gives the display. Multilinearity, $K_{\mathcal{H}} = K_{\mathcal{H}\setminus h_i} + x_iK_{\mathcal{H}/h_i}$, gives $x_i\partial_{x_i}K_{\mathcal{H}} = x_iK_{\mathcal{H}/h_i}$. A mark left in place has $R^{\mathcal{A}/g} = 0$ and $R_h^{\mathcal{A}\setminus g} = 1$. □

Theorem 42.24 (Native gauges along the hinge tree). *As stated.*

Proof. By Proposition 38.16 a point of X_F is a native gauge exactly when $R_e(\alpha) = R_e(\alpha^{-1})$ for every mark e. For a table $\mathcal{X}$, $\alpha_e\partial_e\big[\log K_{\mathcal{X}}(\alpha^{-1})\big] = -R_e^{\mathcal{X}}(\alpha^{-1})$. So by Lemma 42.23, on B_i,

$$R_e(\alpha) - R_e(\alpha^{-1}) = \alpha_e\partial_e\Big[\log K^{\mathcal{A}/g} + \rho\log\gamma\Big](\alpha) + \alpha_e\partial_e\Big[\log K^{\mathcal{A}/g}(\alpha^{-1}) + \rho^*\log\gamma(\alpha^{-1})\Big],$$

with ρ, ρ^* held fixed, that is $\alpha_e\partial_e\big[\log v + \rho\log\gamma + \rho^*\log\gamma^*\big]$, and $\rho\log\gamma + \rho^*\log\gamma^* = \frac{1}{2}(\rho+\rho^*)\log t + \frac{1}{2}(\rho-\rho^*)\log q$: this is $(\star)$.

(a) The hinge values have the degree one, $K_{\mathcal{A}/g}$ is homogeneous, so v and t are invariant under the scale of the cell and q has the degree 2; the derivative of $(\star)$ along the scale is $\rho_i - \rho_i^*$, and then $(\star)$ is $d_{B_i}[\log v_i + \rho_i\log t_i] = 0$.

(b) For a parallel class $R^{\mathcal{A}/g} = 0$ and $R_e^{\mathcal{A}\setminus g} = \alpha_e/A_i$, so with $\varsigma_i = K_{\mathcal{H}/h_i}(\gamma)/K_{\mathcal{H}}(\gamma)$, regular where $A_i = 0$ since $K_{\mathcal{H}}(\gamma) \neq 0$ on X_F, Lemma 42.23 gives $R_e = \rho_i\alpha_e/A_i = \varsigma_i\alpha_e$. The equations on B_i read $\varsigma_i(\alpha)\,\alpha_e = \varsigma_i(\alpha^{-1})\,\alpha_e^{-1}$, $e \in B_i$. If $\varsigma_i(\alpha) = 0$ the left side vanishes and so $\varsigma_i(\alpha^{-1}) = 0$: the class is empty, and conversely then the equations hold for every shape. Otherwise $\alpha_e^2 = \varsigma_i(\alpha^{-1})/\varsigma_i(\alpha)$ is one number on B_i, so $\alpha_e = \eta_e\tau_i$, and $A_i = a_i\tau_i$, $A_i' = a_i\tau_i^{-1}$. Then $\rho_i(\alpha) = a_i\tau_i\varsigma_i(\alpha)$ and $\rho_i(\alpha^{-1}) = a_i\tau_i^{-1}\varsigma_i(\alpha^{-1})$, and the equation $\varsigma_i(\alpha)\tau_i^2 = \varsigma_i(\alpha^{-1})$ reads $\rho_i(\alpha) = \rho_i(\alpha^{-1})$ when $a_i \neq 0$: the occupation of the mark h_i of the core with the variable $a_i\tau_i$ agrees at τ and at τ^{-1}, the native-gauge equation of the weighted core there. An empty class enters the letters through $\gamma_i = A_i$ and $\gamma_i(\alpha^{-1}) = A_i'$ alone (Theorem 21.4). For a pair, $x + y = A_i$ and $x^{-1} + y^{-1} = A_i'$ give $xy = A_i/A_i'$, and $r + r^{-1} = (x+y)^2/(xy) - 2 = A_iA_i' - 2$ for $r = x/y$. For a series class $R_e^{\mathcal{A}\setminus g} = 1$ and $R_e^{\mathcal{A}/g} = 1 - \alpha_e^{-1}/A_i'$, so $R_e = 1 - (1-\rho_i)\alpha_e^{-1}/A_i' = 1 - \varsigma_i'\alpha_e^{-1}$ with $\varsigma_i' = \gamma_iK_{\mathcal{H}\setminus h_i}(\gamma)/K_{\mathcal{H}}(\gamma)$, as $1 - \rho_i = K_{\mathcal{H}\setminus h_i}(\gamma)/K_{\mathcal{H}}(\gamma)$; the same argument runs, and at $\alpha_e = \eta_e\tau_i$, $\gamma_i = 1/A_i' = \tau_i/a_i$ and $v = AA' = a_i^2$.

(c), (d) Theorem 21.4 applied to the hinge minors of the cell, $\mathcal{A}\setminus g = (\mathcal{H}'\setminus g)\langle\mathcal{A}_l'\rangle$ and $\mathcal{A}/g = (\mathcal{H}'/g)\langle\mathcal{A}_l'\rangle$, gives $K_{\mathcal{A}\setminus g} = \prod_l K_{\mathcal{A}_l'/g_l'}\,K_{\mathcal{H}'\setminus g}(\gamma')$ and $K_{\mathcal{A}/g} = \prod_l K_{\mathcal{A}_l'/g_l'}\,K_{\mathcal{H}'/g}(\gamma')$, so the quotient and the product v are as displayed. A parallel node is $\mathcal{H}' = \binom{\{g,x_1,\dots,x_p\}}{1}$, with $K_{\mathcal{H}'\setminus g} = \sum_l x_l$ and $K_{\mathcal{H}'/g} = 1$; a series node is $\binom{\{g,x_1,\dots,x_p\}}{p}$, with $K_{\mathcal{H}'\setminus g} = e_p(x)$ and $K_{\mathcal{H}'/g} = e_{p-1}(x)$. □

Corollary 42.25 (A class is a bubble of classes). *As stated.*

Proof. The bases of $\binom{[2]}{1}\langle\binom{[a]}{1}, \binom{[b]}{1}\rangle$ are one mark of the first class or one of the second (Definition 21.1), which are the bases of $\binom{[s]}{1}$. With $x_l' = t_l/x_l$, $(x_1+x_2)(t_1/x_1 + t_2/x_2) = t_1 + t_2 + t_1r + t_2r^{-1}$.

Its torus fibre integral at the norms (t_1,t_2) is the constant term in r of $\big(\tau-(t_1+t_2+t_1r+t_2r^{-1})\big)^{-1}$, which is $\big((\tau-t_1-t_2)^2-4t_1t_2\big)^{-1/2}$, and Theorem 42.20(ii) gives the first display. The coefficient of z^j in the s-th power is $\sum_{|w|=j}\prod_e w_e!^{-2}=j!^{-2}\sum_{|w|=j}\binom{j}{w}^2$. □

Proposition 42.26 (The value of a table is a closed serif word). *As stated.*

Proof. (i) $K(\mathsf{m}\alpha^{-1})=\sum_T\theta_T\prod_{e\in T}\mathsf{m}_e\alpha_e^{-1}=\alpha^{-\mathcal{E}}\sum_T\theta_T\mathsf{m}^T\alpha^{\mathcal{E}\setminus T}=\alpha^{-\mathcal{E}}\Psi_{\theta\mathsf{m}}(\alpha)$. So $\big(K(\alpha)K(\mathsf{m}\alpha^{-1})\big)^{-k}\alpha^{-\mathbf{1}}=\alpha^{k\mathbf{1}-\mathbf{1}}K^{-k}\Psi_{\theta\mathsf{m}}^{-k}$, the integrand of the period of F_m at $k\mathbf{1}$ (Theorem 8.7), and $m_\mathcal{E}=nk=rk+(n-r)k$ is the balance. The walls do not see the weights: with the floors $d(S)=r-r(\mathcal{E}\setminus S)$ of K and $d^*(S)=|S|-r(S)$ of Ψ on S, $\kappa_S=k|S|-k\,d(S)-k\,d^*(S)=k\big(r(S)+r(\mathcal{E}\setminus S)-r\big)$, positive for every nonempty proper S because the table is connected. So the period converges (Theorem 8.7), and the family is connected with its walls positive at the target, so it has a native gauge (Theorem 8.19(iii)).

(ii) Apply Corollary 18.16, under Theorem 18.13, to F_m, with one share per basis for each active letter; (i) provides the hypotheses. The monomial in the weights is $\prod_T\theta_T^{-a_T}(\theta_T\mathsf{m}^T)^{-b_T}=\prod_T\theta_T^{-a_T-b_T}\prod_e\mathsf{m}_e^{-\sum_{T\ni e}b_T}$. On the fibre, $\mathrm{load}_e=\sum_{T\ni e}a_T+\sum_{T\not\ni e}b_T=k$ and $|\mathbf{b}|=k$ give $\sum_{T\ni e}b_T=\ell_e(\mathbf{a})$, for $e\neq g$ by the pins and for g by the balance, $\sum_e\mathrm{load}_e=r|\mathbf{a}|+(n-r)|\mathbf{b}|=nk$. The formula holds on every wall contour (Theorem 18.13(i)), and the uniform split is one: every share has the real part $k/N>0$, and its load on e is $\frac{k}{N}\big(\#\{T\ni e\}+\#\{T\not\ni e\}\big)=k$. The dimension counts $2N$ shares against two share sums and $n-1$ pins, and these are independent. Given $|\mathbf{b}|=k$ the pins read $\sum_{T\ni e}(a_T-b_T)=0$, $e\neq g$; a vanishing combination $\lambda|\mathbf{a}|+\lambda'|\mathbf{b}|+\sum_{e\neq g}\mu_e\sum_{T\ni e}(a_T-b_T)$, with $\mu_g=0$, has $\lambda+\langle\mu,\mathbf{1}_T\rangle=0$ and $\lambda'-\langle\mu,\mathbf{1}_T\rangle=0$ for every basis T. The points $\mathbf{1}_T$ of a connected table span an affine hyperplane, its base polytope having the dimension $n-1$ (the dimension of the base polytope of a connected matroid, which applies to the bases of a table by the arena property, the exchange property of the bases), so $\langle\mu,\cdot\rangle$ is constant on the hyperplane $\{x_\mathcal{E}=r\}$, $\mu\in\mathbb{R}\mathbf{1}$, and $\mu_g=0$ gives $\mu=0$ and then $\lambda=\lambda'=0$.

(iii) By Theorem 21.4 at α and at $\mathsf{m}\alpha^{-1}$, as in Theorem 42.20(i), $K(\alpha)K(\mathsf{m}\alpha^{-1})=\prod_i v_{\mathcal{A}_i}\,\Phi_\mathcal{H}(\mathbf{x},\mathbf{x}')$ at the hinge pairs (x_i,x_i') of the cells, a mark of the norm m_i left in place having the hinge pair $(\alpha_{h_i},\mathsf{m}_i\alpha_{h_i}^{-1})$ and $v=1$ (Definition 42.19(i)). By Proposition 21.3(iv) the core and the cells are connected, and no marker is a loop or a coloop of the core (Definition 21.1). Integrate each cell with $|B_i|\geq 2$ first, in its scale λ_i and its shape u_i, $\alpha_{B_i}=\lambda_iu_i$: the hinge value is $x_i=\lambda_i\gamma_i(u_i)$ and its partner is t_i/x_i, with $t_i=\gamma_i(u_i)\gamma_i(u_i^{-1})$ the norm of the cell, a function of the shape alone, and $v_{\mathcal{A}_i}$ does not depend on the scale. So $\mathsf{V}_\mathcal{B}(k;\mathsf{m})=\int\mathsf{V}_\mathcal{H}(k;\mathbf{t})\prod_i\rho_i(dt_i)$, where $\mathsf{V}_\mathcal{H}(k;\mathbf{t})$ is the value of the core with the norms t_i on its markers, ρ_i is the image of $v_{\mathcal{A}_i}^{-k}\alpha^{-\mathbf{1}}d\alpha$, on the shapes of $\mathcal{A}_i$, under t_i, and for a mark left in place ρ_i is the unit point mass at m_i. By (ii) the core's word carries the monomial $\prod_i t_i^{-\ell_{h_i}(\mathbf{a})}$, and $\int t^{-\ell}\rho_i(dt)=\widehat{\mathsf{V}}_{\mathcal{A}_i}(k;\ell)$ because $v_\mathcal{A}^{-k}t^{-\ell}=v_\mathcal{A}^{\ell-k}\big(K_{\mathcal{A}\setminus g}(\alpha)K_{\mathcal{A}\setminus g}(\alpha^{-1})\big)^{-\ell}$, γ being $K_{\mathcal{A}\setminus g}/K_{\mathcal{A}/g}$; for a mark left in place it is $\mathsf{m}_i^{-\ell}$.

Take the uniform split of the core as the contour. It does not move with the norms t_i, and on it $\mathrm{Re}\,\ell_{h_i}=kN_{h_i}/N_\mathcal{H}$, with N_h the number of bases of $\mathcal{H}$ containing h, so $0<\mathrm{Re}\,\ell_{h_i}<k$. The hinge minors lie on the balance wall of B: with $n_\mathcal{A}=|B|$ and $r_\mathcal{A}$ the rank of $\mathcal{A}\setminus g$, which is the rank of $\mathcal{A}$, the masses $k\mathbf{1}$ sum to $n_\mathcal{A}k=(k-\ell)\big((r_\mathcal{A}-1)+(n_\mathcal{A}-r_\mathcal{A}+1)\big)+\ell\big(r_\mathcal{A}+(n_\mathcal{A}-r_\mathcal{A})\big)$. Their walls are $\kappa_S=(k-\ell)\,c_{\mathcal{A}/g}(S)+\ell\,c_{\mathcal{A}\setminus g}(S)$, with $c(S)=r(S)+r(B\setminus S)-r$ for each minor, as in (i). Both terms are nonnegative, and they vanish together only if S separates $\mathcal{A}$: if S and $S'=B\setminus S$ separate both minors, then in $\mathcal{A}$ $r(S)+r(S')=r_\mathcal{A}$ and $r(S+g)+r(S'+g)=r_\mathcal{A}+1$, so g lies in the closure of exactly one side, say S', and S, $S'+g$ separate $\mathcal{A}$. The cell is connected, so $\widehat{\mathsf{V}}_\mathcal{A}(k;\ell)$ converges for $0<\mathrm{Re}\,\ell<k$ (Theorem 8.7), and $|\widehat{\mathsf{V}}_\mathcal{A}(k;\ell)|\leq\widehat{\mathsf{V}}_\mathcal{A}(k;\mathrm{Re}\,\ell)$ since $|t^{-\ell}|=t^{-\mathrm{Re}\,\ell}$. On

the contour the real parts are fixed and the stacked Gammas decay exponentially in the imaginary directions, so the iterated integral converges absolutely and the integrals exchange. For a parallel class $\mathcal{A}/g$ has the single empty basis and $\mathcal{A}\setminus g=\binom{C}{1}$, so $\widehat{\mathsf{V}}$ is the period of the centre ray of $\binom{C}{1}$ at the strength ℓ, which is the stated integral of the Gramma (Corollary 18.24 for the dual table and Proposition 8.15, as at the head of Section 42.6).

(iv) At these data the hinge wall of $\mathcal{A}$ is $k|B|-k(r_{\mathcal{A}}-1)-k(|B|-r_{\mathcal{A}})=k$, so $\phi_{\mathcal{A}}=u^{k\mathbf{1}-\mathbf{1}}K_{\mathcal{A}\setminus g}^{-k}\Psi_{\mathcal{A}\setminus g}^{-k}\,d\omega_B$ and $\varrho_{\mathcal{A}}=\mathbf{E}_{\mathcal{A}/g}/\mathbf{E}_{\mathcal{A}\setminus g}$ (Definitions 23.1 and 21.1). For each hinge minor $K(\alpha^{-1})=\alpha^{-B}\Psi(\alpha)$ with its weights, as in (i); so $v_{\mathcal{A}}=\alpha^{-B}\mathbf{E}_{\mathcal{A}/g}$, $K_{\mathcal{A}\setminus g}(\alpha)K_{\mathcal{A}\setminus g}(\alpha^{-1})=\alpha^{-B}\mathbf{E}_{\mathcal{A}\setminus g}$, and the form of $\widehat{\mathsf{V}}_{\mathcal{A}}(k;\ell)$ is $\alpha^{k\mathbf{1}-\mathbf{1}}\mathbf{E}_{\mathcal{A}/g}^{\ell-k}\mathbf{E}_{\mathcal{A}\setminus g}^{-\ell}\,d\alpha$, unchanged by the scale and integrated over any section (Definition 1.1(vii)). On the shape simplex it is $\varrho_{\mathcal{A}}^{\ell-k}\,d\phi_{\mathcal{A}}$, and its integral is the Trailmoment of the image measure with the kernel $x^{\ell-k}$ (Definition 5.2). The two Mellin transforms are Proposition 23.8(iii) at $s=t=\kappa=k$, finite at real $z\in(0,k)$ because $\widehat{\mathsf{V}}_{\mathcal{A}}$ is, the cell being connected (the proof of (iii)), and so at complex z with these real parts. The measure $\rho_{\mathcal{A}}$ of the proof of (iii), the image of $v_{\mathcal{A}}^{-k}\alpha^{-\mathbf{1}}d\alpha$ on the shapes under $t=\varrho_{\mathcal{A}}^{-1}$, is the image of $x^{-k}(\varrho_{\mathcal{A}})_*\phi_{\mathcal{A}}(dx)$ under $x\mapsto x^{-1}$, because $v_{\mathcal{A}}^{-k}\alpha^{-\mathbf{1}}=\varrho_{\mathcal{A}}^{-k}\alpha^{k\mathbf{1}-\mathbf{1}}\mathbf{E}_{\mathcal{A}\setminus g}^{-k}$. So by Proposition 23.8(i), with $\mathsf{g}=\mathsf{G}_{0;(1,-1)}(1,\cdot)$,

$$\int \mathsf{g}(ty)\,\rho_{\mathcal{A}}(dt)=\check{f}_{\mathcal{A}}(y),\qquad \int t^{-k}\mathsf{g}(y/t)\,\rho_{\mathcal{A}}(dt)=f_{\mathcal{A}}(y),$$

and for the one-mark cell of ratio 1, $\rho=\delta_1$ gives g for both, as in Definition 23.19(1).

(v) By Definition 21.1 a set of $\mathcal{A}$ contains g exactly when the basis of $\mathcal{H}'$ it comes from contains h, the mark left in place there being the cell $\binom{\{g,h\}}{1}$. So $\mathcal{A}\setminus g$ and $\mathcal{A}/g$ are given by the formula of that definition at $\mathcal{D}$ and at $\mathcal{C}$, with the same cells and the inherited weights, a marker that is a loop of the minor putting the contraction of its cell into every set and a coloop its deletion; $\mathcal{H}'$, a core, has neither. Expanding the letters over these sets gives Theorem 21.4 for $\mathcal{C}$ and $\mathcal{D}$ as it stands, and at α and at α^{-1}, as in the proof of (iii), the form of $\widehat{\mathsf{V}}_{\mathcal{A}}(k;\ell)$ is $\prod_i v_{\mathcal{A}_i'}^{-k}\,\Phi_{\mathcal{C}}^{\ell-k}\Phi_{\mathcal{D}}^{-\ell}\alpha^{-\mathbf{1}}d\alpha$, with $\Phi_{\mathcal{X}}=K_{\mathcal{X}}(\mathbf{x})K_{\mathcal{X}}(\mathbf{x}')$ at the hinge pairs (x_i,x_i') of the cells, a mark left in place having $v=1$ and the pair $(\alpha_{h_i},\alpha_{h_i}^{-1})$. Integrating each cell of at least two marks in its scale and its shape,

$$\widehat{\mathsf{V}}_{\mathcal{A}}(k;\ell)=\int W(k,\ell;\mathbf{t})\prod_i\rho_{\mathcal{A}_i'}(dt_i),$$
$$W(k,\ell;\mathbf{t})=\int\big(K_{\mathcal{C}}(\mathbf{x})K_{\mathcal{C}}(\mathbf{t}\mathbf{x}^{-1})\big)^{\ell-k}\big(K_{\mathcal{D}}(\mathbf{x})K_{\mathcal{D}}(\mathbf{t}\mathbf{x}^{-1})\big)^{-\ell}\mathbf{x}^{-\mathbf{1}}\,d\mathbf{x},$$

with $\rho=\delta_1$ at a mark left in place. By (i), $W(k,\ell;\mathbf{t})$ is the period at the masses $k\mathbf{1}$ of the family of the four tables $(\mathcal{C},\theta^{\mathcal{C}})$ at $(k-\ell,0)$, $(\mathcal{C},\theta^{\mathcal{C}}\mathbf{t})$ at $(0,k-\ell)$, $(\mathcal{D},\theta^{\mathcal{D}})$ at $(\ell,0)$ and $(\mathcal{D},\theta^{\mathcal{D}}\mathbf{t})$ at $(0,\ell)$, on its balance wall, $pk=(k-\ell)p+\ell p$, with the walls $(k-\ell)\,c_{\mathcal{C}}(S)+\ell\,c_{\mathcal{D}}(S)$, $c(S)=r(S)+r(S')-r$ for each minor and S' the other markers. For real $\ell\in(0,k)$ they are positive: if S and S' separate both minors, then in $\mathcal{H}'$ $r(S)+r(S')=r_{\mathcal{H}'}$ and $r(S+h)+r(S'+h)=r_{\mathcal{H}'}+1$, so h lies in the closure of exactly one side and the two sides separate $\mathcal{H}'$, which is connected (Proposition 21.3(iv)). So the family converges and has a native gauge (Theorems 8.7 and 8.19(iii)), and Corollary 18.16 under Theorem 18.13, with one share on each basis for each of the four letters, gives its word on $\mathcal{Y}_{k,\ell}$. The monomial in the weights is $\prod_T(\theta_T^{\mathcal{C}})^{-a_T}(\theta_T^{\mathcal{C}}\mathbf{t}^T)^{-b_T}\prod_T(\theta_T^{\mathcal{D}})^{-c_T}(\theta_T^{\mathcal{D}}\mathbf{t}^T)^{-d_T}$, and on the fibre $\sum_{T\ni x}(b_T+d_T)=\ell_x(\mathbf{a})+\ell_x(\mathbf{c})$ at every marker, from its load k and $|\mathbf{b}|+|\mathbf{d}|=k$, at the free marker by the balance as in (ii); so the norms enter as $\prod_i t_i^{-\ell_{h_i}(\mathbf{a})-\ell_{h_i}(\mathbf{c})}$, and $\int t^{-\lambda}\rho_{\mathcal{A}_i'}(dt)=\widehat{\mathsf{V}}_{\mathcal{A}_i'}(k;\lambda)$. On the uniform split $\ell_{h_i}(\mathbf{a})+\ell_{h_i}(\mathbf{c})=(k-\ell)p_i+\ell q_i$, with p_i and q_i the fractions of the bases of $\mathcal{C}$ and of $\mathcal{D}$ that contain h_i; $q_i>0$ because deleting a mark of the core makes no loop and $p_i<1$ because

contracting one makes no coloop, so its real part lies in $(0,k)$, and the integrals exchange as in (iii). The pins are independent: a vanishing combination of the four share sums and of the loads at the markers but one, with μ its coefficients on the markers and $\mu=0$ at the free one, makes $\langle\mu,\mathbf{1}_T\rangle$ constant on the bases of $\mathcal{C}$ and constant on those of $\mathcal{D}$; with μ_h the difference of the two constants, $\langle\mu,\cdot\rangle$ is constant on the bases of $\mathcal{H}'$, which is connected, so $\mu\in\mathbb{R}\mathbf{1}$ as in the proof of (ii), $\mu=0$, and then every coefficient vanishes. So the fibre has the dimension $2(N_{\mathcal{C}}+N_{\mathcal{D}})-4-(p-1)$.

(vi) For the parallel node every marker is a loop of $\mathcal{C}$, which has the single basis $\varnothing$ with the weight 1, and $\mathcal{D}=\binom{\{h_1,\dots,h_p\}}{1}$; for the series node $\mathcal{D}$ has the single basis $\{h_1,\dots,h_p\}$, and $\mathcal{C}=\binom{\{h_1,\dots,h_p\}}{p-1}$. So $W(k,\ell;\mathbf{t})$ of the proof of (v) is the value of $\binom{\{h_1,\dots,h_p\}}{1}$ at the strength ℓ with the norms $\mathbf{t}$ in the first case, and $(\prod_i t_i)^{-\ell}$ times the value of $\binom{\{h_1,\dots,h_p\}}{p-1}$ at the strength $k-\ell$ with the norms $\mathbf{t}$ in the second. For $c_1,\dots,c_p>0$ and $\sigma>0$, open $(\sum_i x_i)^{-\sigma}$ and $(\sum_i c_i/x_i)^{-\sigma}$ with the scales λ and w/λ and move λ into $\mathbf{x}$; by Tonelli's theorem and Definition 2.1,

$$\begin{aligned}\int\Big(\sum_i x_i\sum_i\frac{c_i}{x_i}\Big)^{-\sigma}\mathbf{x}^{-\mathbf{1}}\,d\mathbf{x}&=\frac{1}{\Gamma(\sigma)^2}\int_0^\infty w^{\sigma-1}\prod_i\int_0^\infty e^{-\beta-c_iw/\beta}\,\frac{d\beta}{\beta}\,dw\\&=\frac{1}{\Gamma(\sigma)^2}\int_0^\infty w^{\sigma-1}\prod_i\mathsf{g}(c_iw)\,dw.\end{aligned}$$

$K(\mathbf{x})K(\mathbf{t}\mathbf{x}^{-1})$ is $\sum_i x_i\sum_i t_i/x_i$ for $\binom{\{h_1,\dots,h_p\}}{1}$ and $\prod_i t_i\,\sum_i x_i^{-1}\sum_i x_i/t_i$ for $\binom{\{h_1,\dots,h_p\}}{p-1}$, the second of the first form in $\mathbf{x}^{-1}$ with $c_i=1/t_i$. So

$$W(k,\ell;\mathbf{t})=\frac{1}{\Gamma(\ell)^2}\int_0^\infty w^{\ell-1}\prod_i\mathsf{g}(t_iw)\,dw,\qquad W(k,\ell;\mathbf{t})=\frac{(\prod_i t_i)^{-k}}{\Gamma(k-\ell)^2}\int_0^\infty w^{k-\ell-1}\prod_i\mathsf{g}(w/t_i)\,dw,$$

and integrating against $\prod_i\rho_{\mathcal{A}_i'}(dt_i)$ by Tonelli's theorem gives the two formulas by (iv). A series class is the series node with marks left in place.

(vii) The proof of (iii) gives $\mathsf{V}_{\mathcal{B}}(k;\mathsf{m})=\int\mathsf{V}_{\mathcal{H}}(k;\mathbf{t})\prod_i\rho_{\mathcal{A}_i}(dt_i)$, with $\rho=\delta_{\mathsf{m}_i}$ at a mark left in place, and the value of the core with the norms $\mathbf{t}$ is the integral of the proof of (vi) at $\sigma=k$: $\Gamma(k)^{-2}\int_0^\infty w^{k-1}\prod_i\mathsf{g}(t_iw)\,dw$ for the parallel node and $(\prod_i t_i)^{-k}\Gamma(k)^{-2}\int_0^\infty w^{k-1}\prod_i\mathsf{g}(w/t_i)\,dw$ for the series node. By (iv), and with δ_{m_i} giving $\mathsf{g}(\mathsf{m}_iw)$ and $\mathsf{m}_i^{-k}\mathsf{g}(w/\mathsf{m}_i)$, the two formulas follow. □

Lemma 42.27 (The pencil of a class). *As stated.*

Proof. (i) $\alpha_e\partial_e\varphi=A'\alpha_e-A\alpha_e^{-1}$. If $A,A'\neq0$ these vanish together exactly when $\alpha_e^2=A/A'$ for every e, a sign times a scale, of the value $(\sum_e\eta_e)^2\neq0$; nondegeneracy is Proposition 42.9(ii). If $A=0$, then $A'\alpha_e=0$ forces $A'=0$, and if $A'=0$, then $A=0$. (ii) Let x_m leave every compact subset of T_s with $d_y\log\varphi(x_m)\to0$ and $\varphi(x_m)\to t_0\neq0$. Then $A,A'\neq0$, and the scale can be chosen with $A=A'$, so $A^2\to t_0$ and $\partial_{y_e}\log\varphi=(\alpha_e-\alpha_e^{-1})/A\to0$; every $\alpha_e\to\pm1$, and x_m converges in T_s, a contradiction. (iii) The signs with k and with $s-k$ entries -1 are the same points of T_s, the scale -1 exchanging them; S_s is transitive on the signs with k entries -1, and $\eta^{-1}=\eta$. □

Lemma S29 (The pinch)**.** *Let V be a local system on a punctured disc Δ^* about $t=1$ with the monodromy T_1, $j:\Delta^*\to\Delta$, and $\Phi(t,r)=t+1+tr+r^{-1}$ near $(t,r)=(1,-1)$, where $\Phi=0$. Let W be the vanishing cycles at $(1,-1)$ of $j_*V\boxtimes\mathbb{C}$ along Φ at the value 0, ψ the nearby cycles, $T_0=1+\mathrm{var}\circ\mathrm{can}$ on ψ and $T_W=1+\mathrm{can}\circ\mathrm{var}$ on W.*

(a) If $T_1=1$: $\dim W=\mathrm{rk}\,V$ and $T_W=1$, so $(T_0-1)^2=0$.

(b) If $T_1 - 1$ has rank one and square zero: $\dim W = \operatorname{rk} V + 1$, and T_W is -1 on a line and $1 + N'$ on a complement, with N' of rank at most one and square zero. So the eigenvalue -1 of T_0 has the multiplicity at most one, and on the unipotent part $(T_0 - 1)^3 = 0$ with $(T_0 - 1)^2$ of rank at most one.

Proof. With $t = 1 + a$ and $r = -1 + b$, $\Phi = ab - b^2 - b^3 - \cdots$. For fixed a it has a nondegenerate critical point in b, at $b = c(a) = \frac{a}{2} + O(a^2)$, and the Morse lemma in b with the parameter a, which leaves the coordinate a and so the local system untouched, gives $\Phi = g(a) - b'^2$ with $g(a) = \frac{a^2}{4} + O(a^3)$. So Φ is the sum of g, with the coefficients j_*V, and $-b'^2$, with constant coefficients, in separate variables, and $W \cong \phi_g(j_*V) \otimes \phi_{-b'^2}(\mathbb{C})$ with $T_W = T_g \otimes T_{-b'^2}$ (the theorem of Thom and Sebastiani for vanishing cycles with coefficients). The second factor is a line with the monodromy -1. The Milnor fibre of g is a pair of points exchanged by its monodromy, so $\phi_g(j_*V)$ is the cokernel of $V^{T_1} \to V \oplus V$, $v \mapsto (v, v)$, with the monodromy $M(x, y) = (y, T_1 x)$, a half turn, $M^2 = T_1 \oplus T_1$. (a) M is the exchange, -1 on the antidiagonal quotient, and $T_W = 1$. (b) With $N_1 = T_1 - 1$ and $\widetilde{N} = N_1 \oplus N_1$, $U = M(1 - \frac{1}{2}\widetilde{N})$ is an involution commuting with $\widetilde{N}$, $U(x, y) = (y - \frac{1}{2}N_1 y,\ x + \frac{1}{2}N_1 x)$, with the eigenspaces $E_\pm = \{(x, \pm(x + \frac{1}{2}N_1 x))\}$, each of dimension $\operatorname{rk} V$, and $M = \pm(1 + \frac{1}{2}\widetilde{N})$ on $E_\pm$. The diagonal image of $V^{T_1} = \ker N_1$ lies in E_+, with the quotient a line on which $M = 1$, N_1 mapping into its kernel; on E_-, $M = -(1 + \frac{1}{2}N_1)$. Tensoring with -1 gives T_W. Finally $(T_0 - 1)^k = \operatorname{var}(T_W - 1)^{k-1}\operatorname{can}$, and can and var are isomorphisms on the generalized eigenspaces of an eigenvalue other than 1. □

Theorem 42.28 (The class for every size). *As stated.*

Proof. Write $\mathsf{M}(j) = \mathsf{C}_j^{\binom{[s]}{1}}(1)$, extended by 0 to $j < 0$. By Theorem 42.12(iii), $\sum_k c_{s,k}(-j)\mathsf{M}(j - k) = 0$ for $j \in \mathbb{N}$, and for $j < 0$ every term vanishes, so the relation holds on $\mathbb{Z}$. On t^{-j-1} the operator $t\partial_t + 1$ acts as $-j$ and $t^{-k}T_s = \sum_j \mathsf{M}(j - k)t^{-j-1}$, so $\widetilde{A}_s T_s = \sum_j \big(\sum_k c_{s,k}(-j)\mathsf{M}(j - k)\big)t^{-j-1} = 0$. Every $c_{s,k}$ has the degree $s - 1$, so $\widetilde{A}_s$ has the order $s - 1$; its leading coefficient vanishes in $\mathbb{C}^\times$ exactly at the sign values, simply, by the symbol of Theorem 42.12(ii). At $t = \infty$, in $w = 1/t$, $\widetilde{A}_s = c_{s,0}(1 - w\partial_w) + O(w)$ with $c_{s,0}(x) = (-1)^{s+1}x^{s-1}$, so every exponent there is 1.

The rank. V_s lies in the solutions of $\widetilde{A}_s$, of dimension $s - 1$. The closings are positive with $\mathsf{M}(j)^{1/j} \to s^2$, so T_s is singular at $t = s^2$ (Pringsheim's theorem on series with nonnegative coefficients). The value s^2 carries the single nondegenerate native gauge $\mathbf{1}$ and no asymptotic one (Lemma 42.27), so the variation of T_s about s^2 is a nonzero multiple of the period of the vanishing cycle there (the Picard–Lefschetz formula), which lies in V_s. For $t > s^2$ the orthant fibre $\{\varphi = t\} \cap \mathbb{R}^s_{>0}$ is the real vanishing sphere of the minimum $\mathbf{1}$ of φ on the orthant, so that period is the orthant fibre integral P, up to a constant. By Proposition 39.54, applied to the centre ray of $\binom{[s]}{1}$, $(T_\infty - 1)^{s-2}P$ is a nonzero multiple of $V_1 T_s \neq 0$ on the part of P of the eigenvalue 1, which lies in V_s with P. So V_s contains a Jordan block of size $s - 1$: it is the whole space of the solutions, which is that block, (ii). A nonzero sub-local system is stable under T_∞, so it contains the invariant line of the block, spanned by T_s, and with it all of V_s: V_s is irreducible, (i).

The local monodromies. V_s lies in the solutions of $\mathcal{D}[1]$ of the centre ray of $\binom{[s]}{1}$. At a sign value x its vanishing rank is at most 1 by Lemma 42.27 and Lemma 39.50, and $\operatorname{rank}(T_x - 1)$ on the solutions of a regular holonomic module is at most the dimension of its vanishing cycles, which is the vanishing rank; so $\operatorname{rank}(T_x - 1) \leq 1$ on V_s. By Theorem 39.51 and Lemma 42.27(ii) there are no other singular points in $\mathbb{C}^\times$. At ∞, $\operatorname{rank}(T_\infty - 1) = s - 2$. At 0, for $s \geq 3$: by Corollary 42.25 with $(a, b) = (s - 1, 1)$ and Theorem 42.20(iii), V_s is a subquotient of the nearby cycles at the value 0 of the direct image of $\mathcal{H}_C \boxtimes \mathcal{H}_{\mathrm{mark}}$ under the two-sided core of $\binom{[2]}{1}$, C the class of $s - 1$

marks. Modulo the scale, with the mark at $x_2 = x_2' = 1$ and $r = 1/x_1$, the two-sided core is $\Phi(t,r) = t + 1 + tr + r^{-1}$, $t = x_1x_1'$ the norm of C. Off the axes the scale identifies the hinge map of C with its pencil times the scale, so there $\mathcal{H}_C$ is the pullback along t of the module $\mathcal{D}[1]$ of $\binom{[s-1]}{1}$. Near the value 0 the two-sided core has the single critical point $(1,-1)$ on the strata of that module, with none at infinity: $\partial_t\Phi = 1 + r$ and $\partial_r\Phi = t - r^{-2}$ vanish together only at $(1,-1)$; on a line $t = t_*$ the critical values are $(\sqrt{t_*} \pm 1)^2$, which vanish only at $t_* = 1$; on $t = 0$, $\Phi = 1 + r^{-1}$ has none; and at infinity $\partial_t\Phi \to 0$ forces $r \to -1$, and then $r\partial_r\Phi \to 1 - t$, which tends to 0 only at the finite point. Let V' be the local system of the solutions of $\mathcal{D}[1]$ of $\binom{[s-1]}{1}$ near $t = 1$. For odd s the value 1 is not a sign value of $\binom{[s-1]}{1}$, whose sign values are even squares, nor an asymptotic native value (Lemma 42.27(ii)), so that module is a connection near $t = 1$, $T_1 = 1$, and Slemma S29(a) gives $(T_0 - 1)^2 = 0$ on V_s, hence $\operatorname{rank}(T_0 - 1) \leq \frac{s-1}{2}$. For even $s \geq 4$, 1 is the least sign value of $\binom{[s-1]}{1}$; there the vanishing rank is at most 1 (Lemma 39.50), $T_1 - 1$ has rank one by the statement for $s - 1$, so the module is the intermediate extension j_*V' near $t = 1$, and $(T_1 - 1)^2 = 0$ because the vanishing cycle of a nondegenerate critical point in fibres of the odd complex dimension $s - 3$ has the self-intersection 0 (the Picard–Lefschetz formula). Slemma S29(b) gives $\dim E_{-1} \leq 1$ for the generalized eigenspace of -1 and, on the unipotent part E_1 with $N = T_0 - 1$, $N^3 = 0$ and $\operatorname{rank} N^2 \leq 1$. With n_l Jordan blocks of size l on E_1, $\operatorname{rank} N = (\dim E_1 - n_1 + n_3)/2$ with $n_3 \leq 1$, and $\dim E_1 + \dim E_{-1} = s - 1$ is odd; in both cases $\operatorname{rank}(T_0 - 1) \leq \frac{s}{2}$. For $s = 2$, $T_2 = \big(t(t-4)\big)^{-1/2}$, with $T_0 = -1$, and every statement is read off it.

The count. Let $s \geq 3$ and let $\mathcal{V}$ be the intermediate extension of V_s to $\mathbb{P}^1$. A global section is fixed by T_∞, so it is a multiple of T_s, which is not fixed by the monodromy about s^2: there is none. A functional fixed by the monodromy kills the image of $T_\infty - 1$, which contains T_s because the block has the size $s - 1 \geq 2$, and then all of V_s: there is none. So $0 \geq \chi(\mathbb{P}^1, \mathcal{V}) = 2(s-1) - \sum_x \operatorname{rank}(T_x - 1)$ (the Euler characteristic formula for the intermediate extension of a local system on the projective line). With the bounds above and the h sign values, $2s - 2 \leq (s-2) + h + \operatorname{rank}(T_0 - 1)$, so $\operatorname{rank}(T_0 - 1) \geq s - h = \lfloor s/2 \rfloor$; the upper bounds are $\lfloor s/2 \rfloor$ as well, so equality holds throughout, and every sign value has $\operatorname{rank}(T_x - 1) = 1$.

The exponents. At a sign value the leading coefficient of $\widetilde{A}_s$ vanishes simply, so $s - 2$ exponents are $0, \dots, s - 3$, and the last one is that of the period of the vanishing cycle of a nondegenerate critical point on T_s, of dimension $s - 1$, which is $\frac{s-3}{2}$. At 0, $t^h\widetilde{A}_s = \sum_k t^{h-k}c_{s,k}(t\partial_t + 1 - k)$, so the exponents are the roots ρ of $c_{s,h}(\rho + 1 - h)$; $c_{s,h}$ vanishes to the order two at $-1, \dots, -(h-1)$ (Theorem 42.12(ii)), which gives $\rho = 0, \dots, h - 2$, each twice, and for even s one more root. The sum of all the exponents of an operator of order $s - 1$ with $h + 2$ singular points, all regular, is $h\binom{s-1}{2}$ (the Fuchs relation); the sign values contribute $h\frac{(s-3)(s-1)}{2}$ and ∞ contributes $s - 1$, which leaves $\frac{(s-1)(h-2)}{2}$ for $t = 0$: for odd s this is the sum of the double list, and for even s the extra exponent is $\frac{(s-1)(s-4)}{4} - \frac{(s-4)(s-2)}{4} = \frac{s}{4} - 1$. For odd s the blocks at 0 follow from $(T_0 - 1)^2 = 0$ and the rank. □

Proposition 42.29 (The hinge module of a class). *As stated.*

Proof. (a) The Fourier side. Under the Fourier transform $x \mapsto -\partial_\xi$, $\partial_x \mapsto \xi$, $x' \mapsto -\partial_{\xi'}$, $\partial_{x'} \mapsto \xi'$, the direct image of the functions along (A, A') becomes the top cohomology of the relative forms on $(\mathbb{C}^\times)^s$ over $\mathbb{C}[\xi, \xi']$ twisted by $\exp\big(-\sum_e(\xi\alpha_e + \xi'\alpha_e^{-1})\big)$, on which ∂_ξ and $\partial_{\xi'}$ act by $\partial_\xi - A$ and $\partial_{\xi'} - A'$ (the Fourier transform of a direct image is the exponentially twisted direct image). That complex is the tensor product over $\mathbb{C}[\xi, \xi']$ of s copies of the two-term complex of one mark, and the top cohomology of a tensor product of two-term complexes of free modules is the tensor product of their top cohomologies, a cokernel; so the transform is $\mathcal{B}^{\otimes s}$, with $\mathcal{B}$ the top cohomology

of one mark, the derivations acting by the Leibniz rule, and the generator goes to $v^{\otimes s}$, $v = [d\alpha/\alpha]$. In $\mathcal{B}$, $\partial_\xi \partial_{\xi'} v = [\alpha\alpha^{-1} d\alpha/\alpha] = v$, and $(\xi\partial_\xi - \xi'\partial_{\xi'})v = -[(\xi - \xi'\alpha^{-2})d\alpha] = 0$, the class of the twisted differential of 1; so $\vartheta^2 v = zv$ with $\vartheta = \xi\partial_\xi$ and $z = \xi\xi'$. The operator $\sum_k z^k q_k(\vartheta)$ of Theorem 42.12(i) annihilates every product of s solutions of $\vartheta^2 u = zu$, and its proof uses only that relation and the Leibniz rule; so it annihilates $v^{\otimes s}$, and transformed back, with $\vartheta \mapsto -x\partial_x - 1$ and $z \mapsto \partial_x \partial_{x'}$,

$$\sum_{k=0}^{h} (\partial_x \partial_{x'})^k q_k(-x\partial_x - 1)\,[\omega] = 0, \qquad E[\omega] = 0,$$

the second from $\vartheta - \xi'\partial_{\xi'} \mapsto -E$.

(b) One factor comes off. Since $\partial_x \partial_{x'}\, xx' = (x\partial_x + 1)(x'\partial_{x'} + 1)$ and $q_0(-x\partial_x - 1) = (-1)^{s+1}(x\partial_x + 1)^{s+1}$,

$$\sum_{k=0}^{h} (\partial_x \partial_{x'})^k q_k(-x\partial_x - 1) = \partial_x \partial_{x'}\, \widetilde{B} + (-1)^{s-1}(x\partial_x + 1)^s\, E,$$

so $\partial_x \partial_{x'} \widetilde{B}[\omega] = 0$. On functions of t, $x\partial_x$ and $x'\partial_{x'}$ act as $\theta = t\partial_t$ and $\partial_x \partial_{x'}$ as $t^{-1}\theta^2$, with $(t^{-1}\theta^2)^{k-1} = t^{-(k-1)} \prod_{m=0}^{k-2} (\theta - m)^2$. On the other side $c_{s,k}(\theta + 1)\, t^{-k} = t^{-k} c_{s,k}(\theta + 1 - k)$ and $c_{s,k}(\theta + 1 - k) = q_k(-\theta - 1) \prod_{m=0}^{k-2} (\theta - m)^2$, while the term $k = 0$ is $(-1)^{s+1}(\theta+1)^{s-1} = (-\theta-1)^{s-1}$. So $t^{h-1}\widetilde{B} = \sum_k t^{h-k} c_{s,k}(\theta + 1 - k) = t^h \widetilde{A}_s$ on functions of t.

(c) No further periods. Off the axes the scale identifies the fibres of (A, A') with those of $\varphi = AA'$, and the periods of $[\omega]$ at (x, x') with the periods of $[1]$ at $t = xx'$. By (b) every period g of $[1]$ has $\partial_t \theta\, (t\widetilde{A}_s g) = 0$, so $t\widetilde{A}_s g \in \mathbb{C} + \mathbb{C} \log t$. If it is not 0, then, continuing g once about $t = \infty$ and subtracting when $\log t$ occurs, some period g_1 has $t\widetilde{A}_s g_1 = 1$. At $t = \infty$ every exponent of $\widetilde{A}_s$ is 1, with the multiplicity $s - 1$, so the right side t^{-1} of $\widetilde{A}_s g_1 = t^{-1}$ is resonant and forces in g_1 the term $t^{-1}(\log t)^{s-1}$ with a nonzero coefficient: $(T_\infty - 1)^{s-1} g_1 \neq 0$, a Jordan block of size s among the periods of the cohomology of degree $s - 2$ of the fibres, where the monodromy theorem allows at most $s - 1$. So every period of $[1]$ is a solution of $\widetilde{A}_s$, and these are V_s (Theorem 42.28(i)): (ii).

(d) $\widetilde{B}$ itself. Put $g = \widetilde{B}[\omega]$. Then $\partial_x \partial_{x'} g = 0$ by (b), and $Eg = 0$, as $\widetilde{B}$ commutes with E. By (c) all the periods of g vanish, so g is supported on the axes and the hyperbolas. The module $\mathcal{D}g$ is a quotient of $\mathcal{D}/(\mathcal{D}\partial_x \partial_{x'} + \mathcal{D}E)$, whose characteristic variety lies in $\{\eta\eta' = 0,\ x\eta = x'\eta'\} = T^*_P \cup T^*_X \cup T^*_{X'}$; so g is supported on $X \cup X'$. Near a point of $X \setminus O$ a section supported on X is $\sum_k n_k\, \partial_x^k \delta(x)$; $\partial_x \partial_{x'}$ kills it only if every n_k is constant along X, and then E multiplies its k-th term by $-(k + 1)$; so $g = 0$ there, and likewise near $X' \setminus O$. A nonzero section $\sum c_{ab} \partial_x^a \partial_{x'}^b \delta$ at O is not killed by $\partial_x \partial_{x'}$. So $g = 0$: (i).

(e) The axes. By (i), $\mathcal{H}_C$ is a quotient of $N_s = \mathcal{D}/(\mathcal{D}\widetilde{B} + \mathcal{D}E)$. Near a point of $X' \setminus O$, in the coordinates $t = xx'$ and $y = x$, $E = y\partial_y$ and $\widetilde{B} \equiv t\widetilde{A}_s$ modulo $\mathcal{D}E$, so N_s is $\mathcal{D}_t/\mathcal{D}_t\, t\widetilde{A}_s$ times $\mathcal{O}_y$, and the multiplicity of $T^*_{X'}$ in its characteristic cycle is the order at $t = 0$ of the leading coefficient of $t\widetilde{A}_s$, which is $1 + (s - 1 - h) = \lfloor s/2 \rfloor$, the leading coefficient of $\widetilde{A}_s$ being t^{s-1} times a polynomial in t^{-1} of the degree h with a nonzero constant term. The multiplicity in $CC(\mathcal{H}_C)$ is at least $\operatorname{rank}(T_0 - 1) = \lfloor s/2 \rfloor$, so it is $\lfloor s/2 \rfloor$, that of the intermediate extension; likewise on X. Along H_a it is the vanishing rank at a^2 of the module of $[1]$, which is 1 (Lemma 39.50 and Theorem 42.28). At O and for odd s, q_h is a nonzero constant, its degree being at most $s + 1 - 2h = 0$, so the principal symbol of $\widetilde{B}$ at $x = x' = 0$ is $q_h(\eta\eta')^{h-1}$, which vanishes only on $\{\eta\eta' = 0\}$, covered by T^*_X and $T^*_{X'}$: T^*_O is not a component, $m_s(O) = 0$.

(f) Simplicity. The Fourier transform is an equivalence, so it carries the composition factors of $\mathcal{H}_C$ to those of $\mathcal{D}v^{\otimes s}$. On $\xi\xi' \neq 0$, v and ϑv are a basis of $\mathcal{B}$, and the symmetric tensors

with k factors ϑv span a submodule containing $v^{\otimes s}$, the symmetric power $\operatorname{Sym}^s \mathcal{B}$, of rank $s+1$ and irreducible because the differential Galois group of $\vartheta^2 - z$ is SL_2 (Kolchin's theorem on that equation). So exactly one composition factor is nonzero on $\xi\xi' \neq 0$; every other one is supported on $\xi\xi' = 0$, and transformed back it is pulled back from a coordinate line. The intermediate extension of the local system of $\mathcal{H}_C$ is singular along the H_a, so it is the factor that is nonzero on $\xi\xi' \neq 0$. Any other factor has the generic rank 0, the local system having the rank $s-1$ of V_s, and is pulled back from a coordinate line, so it is $\mathcal{O}_x \boxtimes \delta(x')$ or $\delta(x) \boxtimes \mathcal{O}_{x'}$, a delta at O transforming to a factor that is nonzero on $\xi\xi' \neq 0$; by (e) the axes carry no more than the intermediate extension. So $\mathcal{H}_C$ is the intermediate extension: (iii).

(g) The origin. By (iii), $m_s(O)$ is that of the intermediate extension F. By the local index formula for constructible complexes on a surface, the Euler characteristic of the stalk of F at O is $(s-1) - 2\lfloor s/2 \rfloor + m_s(O)$, the axes being smooth curves through O and the hyperbolas avoiding it. Near O the local system has the monodromy T_0 about both axes, and the stalk is the part in the degrees below the middle of the cohomology of the link, a three-sphere through which the axes pass as two linked circles, with coefficients in the intermediate extension along the axes. Cover the sphere by tubes about the two circles, each with the cohomology $\ker(T_0 - 1)$ in the degrees 0 and 1, glued along a torus on which both generators act by T_0; the Mayer–Vietoris sequence gives $H^0 = \ker(T_0 - 1)$ and $H^1 = \ker(T_0 - 1) \cap \operatorname{im}(T_0 - 1)$, so the stalk has the Euler characteristic n_1, and $m_s(O) = n_1 + 2\lfloor s/2 \rfloor - (s-1)$. For odd s every unipotent block has the size 2 and T_0 is unipotent, so this is 0, as in (e); for even s it is $1 + n_1$. For $s = 2$ the module is explicit: $\mathcal{H}_2 = \mathcal{O} \cdot (xx')^{-1/2}(xx' - 4)^{-1/2}$ on the part of the character of the exchange of the two marks, with the cycle of $x^{-1/2} \boxtimes x'^{-1/2}$ at the origin: the origin, both axes and the zero section, each once. □

Corollary 42.30 (The periods of a class are not unipotent). *As stated.*

Proof. Let G be the Zariski closure of the monodromy group of V_s, $s \geq 3$. The monodromy at $t = \infty$ is a unipotent Jordan block of size $s - 1 \geq 2$ (Theorem 42.28(ii)), which generates a connected unipotent group of positive dimension in G°. If G° were solvable, its unipotent radical would be a nontrivial normal subgroup of G whose fixed vectors form a proper nonzero subspace stable under G, against the irreducibility of V_s (Theorem 42.28(i)); so G° is not solvable, and a unipotent group is solvable. A function whose continuations span a local system with a unipotent subgroup of finite index in its monodromy has a monodromy closure with a unipotent identity component; for a nonzero $F \in V_s$ the continuations span a nonzero sub-local system of V_s, which is V_s, whose monodromy closure is G, and G° is not unipotent. Iterated integrals of logarithmic forms with algebraic letters, and their combinations with algebraic coefficients, have local systems that become unipotent on a finite cover, since sums, products and algebraic coefficients keep that property. □

Theorem 42.31 (The sources in the hinge space). *As stated.*

Proof. The singular support of $\mathcal{H}_C$ is the support of its characteristic cycle, given by Proposition 42.29(iv); a mark has the hinge map $(\alpha_h, \alpha_h^{-1})$ onto H_1, with the module of H_1. By Theorem 42.20(iii) every singular value of $\mathcal{D}_{\mathcal{B}}[1]$ is one of the direct image of $\boxtimes_i \mathcal{H}_{C_i}$ under the two-sided core, whose characteristic variety is the product of the characteristic varieties. A direct image under Φ is a connection over a value t_0 near which the graph of $d\Phi$, the covectors $\lambda\, d\Phi$, meets the characteristic variety of the module only in the zero section and no such meeting escapes to infinity (the estimate of the characteristic variety of a direct image, with Rabier's condition at infinity as in the proof of Theorem 39.51). A covector $\lambda\, d\Phi$ with $\lambda \neq 0$ lies in the conormal of a stratum W exactly when $d\Phi$ vanishes on the tangent space of W, a critical point of $\Phi|_W$. □

Theorem 42.32 (The source count bounds the vanishing ranks). *As stated.*

Proof. By Theorem 42.20(iii), $r_{t_0}(\mathcal{D}_{\mathcal{B}}[1])$ is at most the vanishing rank at t_0 of the submodule of N generated by the image of the product of the generators, which lies in the part of N on which Γ acts by the character of [1], Γ acting on N because it preserves $\Phi_{\mathcal{H}}$ and the product of the hinge modules. The vanishing rank is the dimension of the vanishing cycles, as in the proof of Lemma 39.50. Under the stated conditions the characteristic cycle of N over t_0 is the intersection of $CC(\boxtimes_i \mathcal{H}_{C_i}) = \prod_i CC(\mathcal{H}_{C_i})$ with the graph of $d\Phi_{\mathcal{H}}$ (Kashiwara's index formula for direct images), and the components of the product are the T^*_W with the multiplicities $m(W)$. □

Proposition 42.33 (Local contributions). *As stated.*

Proof. (a) A weighted point is the image of an orbit of native gauges of $\mathcal{B}$, the classes being signs times scales (Theorem 42.24(b)), and Lemma 39.50 bounds the vanishing rank there by the number of orbits. (b) The vanishing cycles at the points of an orbit of Γ form the representation induced from the stabilizer, which contains each character of Γ at most as often as the stabilizer's representation contains its restriction (Frobenius reciprocity); two points exchanged, each with a trivial stabilizer, give the regular representation of the exchange tensored with a space of the dimension $m(W)$. (c) At a nondegenerate critical point of $\Phi|_W$ the graph of $d\Phi$ meets T^*_W transversally in one point, of the intersection number 1, weighted by $m(W)$. For an odd corner $m(W) = m_{s_i}(X) = \frac{s_i - 1}{2}$, the other classes contributing $m(H_a) = 1$, and $m_{s_i}(O) = 0$ (Proposition 42.29(iv)); the Cremona exchanges X and X', and (b) gives the pair. (d) Each class of I carries $m(P) = s_i - 1$ and each other class $m(H_a) = 1$, and (c) applies. (e) For a clean intersection of the graph of $d\Phi$ with T^*_W along a curve Z with a constant multiplicity, the intersection number is the Euler number of the excess bundle, which on the conormal of a critical curve is $-\chi(Z)$ times the multiplicity, the contributions of compact ends excluded by hypothesis (the excess intersection formula). □

50.42 Chapter 43: arithmetic along a ray

Throughout, Stirling's formula is $\log\Gamma(z) = (z - \frac{1}{2})\log z - z + \frac{1}{2}\log 2\pi + O(|z|^{-1})$ as $|z| \to \infty$ with $|\arg z| \le \pi - \delta$; it applies below to $\Gamma(k - a)$ and to $N! = \Gamma(N + 1)$ with a fixed and $k, N \to +\infty$ along the reals, so that the arguments stay in a sector around the positive axis.

Lemma S30. *Let $\Bbbk$ be a subfield of $\mathbb{C}$. Let $X(n+1) = M(n)\,X(n)$ for the integers $n \ge n_2$, with $X(n) \in \mathbb{C}^m$ and $M(n)$ an $m \times m$ matrix whose entries are rational functions of n with coefficients in $\Bbbk$ and whose determinant is not the zero function, and let $\psi(n) = \ell\, X(n)$ for a fixed row vector $\ell \in \Bbbk^{1\times m}$. Then ψ satisfies, for all large n, a recurrence $\sum_{i=0}^{h} a_i(n)\,\psi(n+i) = 0$ with $a_i \in \Bbbk[n]$, $h \le m$ and $a_0 a_h \ne 0$.*

Proof. If $\ell = 0$, $\psi = 0$ satisfies $\psi(n) = 0$. Otherwise put $\mathbf{r}_0 = \ell$ and $\mathbf{r}_i(n) = \ell\, M(n+i-1)\cdots M(n)$, row vectors over the field $\Bbbk(n)$; then $\psi(n+i) = \mathbf{r}_i(n)X(n)$ wherever the entries are defined, and $\mathbf{r}_i(n) = \mathbf{r}_{i-1}(n+1)M(n)$. The $m+1$ vectors $\mathbf{r}_0, \dots, \mathbf{r}_m$ are dependent over $\Bbbk(n)$; let $h \ge 1$ be the least index with $\mathbf{r}_0, \dots, \mathbf{r}_h$ dependent, and $\sum_{i=0}^{h} a_i \mathbf{r}_i = 0$ with $a_i \in \Bbbk[n]$ after clearing denominators. By minimality $a_h \ne 0$. If $a_0 = 0$, then $\sum_{i=1}^{h} a_i(n)\mathbf{r}_{i-1}(n+1)M(n) = 0$, and $M(n)$ is invertible over $\Bbbk(n)$, so $\sum_{i=1}^{h} a_i(n)\mathbf{r}_{i-1}(n+1) = 0$; replacing n by $n-1$, an automorphism of $\Bbbk(n)$, gives a dependence among $\mathbf{r}_0, \dots, \mathbf{r}_{h-1}$ with the coefficient $a_h(n-1) \ne 0$, against minimality. So $a_0 \ne 0$, and $\sum_i a_i(n)\psi(n+i) = \big(\sum_i a_i(n)\mathbf{r}_i(n)\big)X(n) = 0$ for all n beyond the poles of the entries. □

Theorem 43.1 (Closing one free share along a ray). *As stated.*

Proof. (i) For an integer $r \ge 0$ and x off the poles, $\Gamma(x+r) = (x)_r\Gamma(x)$ (1.1(v)) and $\Gamma(x-r) = \Gamma(x)/(x-r)_r = (x)_{-r}\Gamma(x)$ (1.3(iii)). Applied to every Gamma of W_k with $x = \epsilon_\gamma a + b_\gamma$ and $r = ku_\gamma$ of either sign this is $W_k = W_0\, g_k$; the factors of g_k have integer coefficients.

(ii) The upper Gammas have poles where $\epsilon_\alpha a + b_\alpha + ku_\alpha \in -\mathbb{N}$, at integers since $\epsilon_\alpha = \pm 1$; the lower ones contribute the entire factors $1/\Gamma$. For $n > n_1$ the arguments at $a = -n+\varepsilon$ are $-N_\gamma(n)+\varepsilon$ on A_+, $N_\gamma(n)+1-\varepsilon$ on A_-, $-N_\gamma(n)+\epsilon_\gamma\varepsilon$ on B_+ and $N_\gamma(n)+1-|\epsilon_\gamma|\varepsilon$ on B_-, with $N_\gamma(n) \in \mathbb{N}$, and $N_\gamma(n)$ is $|\epsilon_\gamma|n$ plus an integer. By 5.14, $\Gamma(-N+\delta) = (-1)^N\delta^{-1}\Gamma(1+\delta)\Gamma(1-\delta)/\Gamma(1+N-\delta)$ for $N \in \mathbb{N}$ and $|\delta| < 1$. Put $s_\gamma = 1$ on $A_- \cup B_+$ and $s_\gamma = -1$ on $A_+ \cup B_-$. Then

$$W_k(-n+\varepsilon) = (-1)^{\sum_{A_+\cup B_+} N_\gamma} \prod_{B_+} \epsilon_\gamma \cdot \varepsilon^{-w} \prod_\gamma \Gamma\big(1+N_\gamma - |\epsilon_\gamma|\varepsilon\big)^{s_\gamma} \frac{\prod_{A_+}\Gamma(1+\varepsilon)\Gamma(1-\varepsilon)}{\prod_{B_+}\Gamma(1+\epsilon_\gamma\varepsilon)\Gamma(1-\epsilon_\gamma\varepsilon)}.$$

At $\varepsilon = 0$ the factor after ε^{-w} is $\prod_\gamma (N_\gamma!)^{s_\gamma}$, which gives C_n as stated, nonzero and rational. By 5.13 at the integer $b = N \ge 0$, where the lattice input $\mathbb{I}_{N+\mathbb{Z}}$ is $\mathbb{I}_\mathbb{Z}$, $\log\Gamma(1+N-\delta) = \log N! + \sum_{i\ge1}\frac{\delta^i}{i}(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_\mathbb{Z})((N,\infty))$, the index-one value regularized, and at $N=0$ with $\pm\delta$, $\log\Gamma(1+\delta)+\log\Gamma(1-\delta) = \sum_{j\ge1}\frac{\delta^{2j}}{j}(\mathsf{T}_{2j;(1)}[x]\,\mathbb{I}_\mathbb{Z})((0,\infty))$. So $W_k(-n+\varepsilon) = C_n\varepsilon^{-w}\exp\big(\sum_i \Lambda_{n,i}\varepsilon^i\big)$ with

$$\Lambda_{n,i} = \frac{1}{i}\sum_\gamma s_\gamma|\epsilon_\gamma|^i\,(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_\mathbb{Z})((N_\gamma(n),\infty)) + [i \text{ even}]\,\frac{2}{i}\Big(|A_+| - \sum_{B_+}\epsilon_\gamma^i\Big)(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_\mathbb{Z})((0,\infty)).$$

The cut relation (5.3, with the regularized values at index one) gives $(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_\mathbb{Z})((N,\infty)) = (\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_\mathbb{Z})((0,\infty)) - (\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_\mathbb{Z})((0,N])$. The balance of the slopes gives

$$\sum_\gamma s_\gamma|\epsilon_\gamma| = \#A_- - \#A_+ + \sum_{B_+}\epsilon_\gamma - \sum_{B_-}|\epsilon_\gamma| = -\sum_A \epsilon_\alpha + \sum_B \epsilon_\beta = 0,$$

so at $i=1$ the regularized value drops out and $\Lambda_{n,1} = -\sum_\gamma s_\gamma|\epsilon_\gamma|\,(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_\mathbb{Z})((0,N_\gamma(n)])$, while for $i \ge 2$, $\Lambda_{n,i}$ is $(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_\mathbb{Z})((0,\infty))$ times $\frac{1}{i}\sum_\gamma s_\gamma|\epsilon_\gamma|^i + [i \text{ even}]\frac{2}{i}(|A_+| - \sum_{B_+}\epsilon_\gamma^i)$, less $\frac{1}{i}\sum_\gamma s_\gamma|\epsilon_\gamma|^i(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_\mathbb{Z})((0,N_\gamma(n)])$. These coefficients depend on the slopes alone.

For $n, n+1 > n_1$, $N_\gamma(n+1) = N_\gamma(n) + |\epsilon_\gamma|$, so $N_\gamma(n+1)!/N_\gamma(n)! = (N_\gamma(n)+1)_{|\epsilon_\gamma|}$ and

$$\rho(n) = \frac{C_{n+1}}{C_n} = (-1)^{|A_+|+\sum_{B_+}\epsilon_\gamma}\prod_\gamma \big(N_\gamma(n)+1\big)_{|\epsilon_\gamma|}^{s_\gamma},$$

a rational function with integer coefficients; with $\rho = \rho_1/\rho_2$ in polynomials, $\rho_2(n)C_{n+1} - \rho_1(n)C_n = 0$ is a recurrence of order one with both coefficients nonzero, so the tier is at most one (38.11). By Stirling's formula $\log N! = N\log N - N + O(\log(N+2))$, and with $N_\gamma(n) = |\epsilon_\gamma|n + O(1)$,

$$\log|C_n| = \sum_\gamma s_\gamma\big(|\epsilon_\gamma|n\log n + |\epsilon_\gamma|n\log|\epsilon_\gamma| - |\epsilon_\gamma|n\big) + O(\log n) = n\log r_W + O(\log n),$$

the terms in $n\log n$ and in n cancelling by $\sum_\gamma s_\gamma|\epsilon_\gamma| = 0$, and $|\epsilon_\gamma|\log|\epsilon_\gamma| = 0$ on A. So $|C_n|^{1/n} \to r_W$.

The residue at $-n$ is the coefficient of ε^{-1}, $C_n[\varepsilon^{w-1}]\exp(\sum_i \Lambda_{n,i}\varepsilon^i)$, which is 0 when $w \le 0$, the exponential having no negative powers. For $w \ge 1$ it is $C_n\sum\prod_i \Lambda_{n,i}^{m_i}/m_i!$ over $\sum_i im_i = w-1$,

a polynomial with rational coefficients in $\Lambda_{n,1},\dots,\Lambda_{n,w-1}$; inserting the combinations above gives the stated polynomial, each monomial of total index $w-1$.

(iii) Moving the line to the left, the arguments of the Gammas of A_+ fall and cross their poles, those of A_- rise and cross none, and the lower Gammas contribute entire factors; under the hypothesis of the closing, 4.5, with the Laurent coefficients at coincident poles, gives the integral as the sum of the residues at the integers $-n<c$. At each of the finitely many integers $-n<c$ with $n\le n_1$ the residue is a Laurent coefficient of finitely many Gammas at integer arguments: by 5.14 and 5.13 each is a nonzero rational number times the exponential of a series whose coefficient of ε^i is a rational combination of $(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ and of heads at integer cuts, which are rational; the coefficient of $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ is $-\epsilon_\alpha\varepsilon$ for an upper Gamma and $\epsilon_\beta\varepsilon$ for a lower one, whatever the sign of the argument, and these cancel by the balance. So these residues are rational combinations of products of $(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$, $i\ge 2$. For $n>n_1$, expand the polynomial of (ii) into monomials: each is a rational number times a product of Trailmoments $(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ times $\psi(n)$ for one of the finitely many products ψ of the statement, the heads of the monomial having total index at most $w-1$. Since $|(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,N])|\le 1+\log(N+1)$ for $i\ge 1$ and $N_\gamma(n)$ grows linearly, $|\psi(n)|\le|C_n|\,(c'\log n)^w$ for large n, of root rate $r_W<1$, so $\sum_{n>n_1}|\psi(n)|<\infty$ (1.1(viii)); the sum of the residues, a finite sum of absolutely convergent series, is the stated combination.

Each ψ is live: C_n is a product of factorials of the moving data, a stacked Gamma, and the heads are Trailmoments at the moving cut. For the recurrence put $H_l(n)=(\mathsf{T}_{i_l;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,N_{\gamma l}(n)])$; then $H_l(n+1)=H_l(n)+\eta_l(n)$ with $\eta_l(n)=\sum_{N_{\gamma l}(n)<j\le N_{\gamma l}(n)+|\epsilon_{\gamma l}|}j^{-i_l}$, a rational function of n with rational coefficients. The vector $X(n)=\big(C_n\prod_{l\in T}H_l(n)\big)_{T\subseteq\{1,\dots,q\}}$ satisfies

$$X(n+1)_T=\rho(n)\sum_{U\subseteq T}\Big(\prod_{l\in T\setminus U}\eta_l(n)\Big)X(n)_U,$$

a matrix $\rho(n)$ times a unitriangular one in the order of inclusion, of determinant $\rho(n)^{2^q}\ne 0$. Lemma S30 with ℓ the coordinate of $T=\{1,\dots,q\}$ gives the recurrence of order at most 2^q with nonzero extreme coefficients.

(iv) At the steps k and k', $N_\gamma(n)$ differs by $-(k-k')u_\gamma$ on $A_+\cup B_+$ and by $(k-k')u_\gamma$ on $A_-\cup B_-$, a constant t_γ. So the sign of C_n changes by a constant, and $N_\gamma(n)!$ at k is $N_\gamma(n)!$ at k' times $(N_\gamma(n)+1)_{t_\gamma}$ or divided by $(N_\gamma(n)+t_\gamma+1)_{-t_\gamma}$, the data at k'; the quotient of the two C_n is a rational function $R_0(n)$ with rational coefficients. Likewise $(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,N+t])$ is $(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,N])$ plus or minus the finite sum of j^{-i} between N and $N+t$, a rational function $\eta'(n)$. Hence, with H'_l the heads at k',

$$\psi^{(k)}(n)=R_0(n)\,C_n^{(k')}\prod_l\big(H'_l(n)+\eta'_l(n)\big)=\sum_{T\subseteq\{1,\dots,q\}}R_0(n)\prod_{l\notin T}\eta'_l(n)\;C_n^{(k')}\prod_{l\in T}H'_l(n),$$

and each $C_n^{(k')}\prod_{l\in T}H'_l(n)$ is an input of (iii) at the step k', its heads a sub-multiset of those of ψ. Inserting this into (iii) at the step k, and adding the finitely many terms between the two bounds n_1, which are rational combinations of products of $(\mathsf{T}_{i;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$, $i\ge 2$, by the argument for $n\le n_1$ in (iii), gives the last statement; the sums $\sum_n R(n)\psi^{(k')}(n)$ converge absolutely, $\psi^{(k')}$ having root rate $r_W<1$.

Closing to the right of $W_k(a)$ is closing to the left of $a\mapsto W_k(-a)$, the word with every slope negated, which is again balanced. □

Proposition 43.2 (Paired words). *As stated.*

Proof. Write $N_\gamma(n) = |\epsilon_\gamma| n + e_\gamma$ with $e_\gamma \in \mathbb{Z}$. By the proof of 43.1(ii),

$$\rho(n) = \frac{C_{n+1}}{C_n} = (-1)^{|A_+| + \sum_{B_+} \epsilon_\gamma} \, r_W \prod_\gamma \prod_{t=1}^{|\epsilon_\gamma|} \big(n + \theta_{\gamma,t}\big)^{s_\gamma}, \qquad \theta_{\gamma,t} = \frac{e_\gamma + t}{|\epsilon_\gamma|},$$

using $(N+1)_v = v^v \prod_{t=1}^{v} (n + (e+t)/v)$ for $N = vn + e$ and $\prod_\gamma |\epsilon_\gamma|^{|\epsilon_\gamma| s_\gamma} = r_W$. For a fixed γ with $|\epsilon_\gamma| = v$ the $\theta_{\gamma,t}$ are v consecutive multiples of $\frac{1}{v}$, so modulo $\mathbb{Z}$ they meet each class j/v once. For $v \geq 1$ put $m_v = \sum_{|\epsilon_\gamma| = v} s_\gamma$, so that $m_v = \#\{\beta : \epsilon_\beta = v\} - \#\{\beta : \epsilon_\beta = -v\}$ for $v \geq 2$, and $\sum_v v\, m_v = \sum_\gamma s_\gamma |\epsilon_\gamma| = 0$ by the balance. The signed number of the $-\theta_{\gamma,t}$ in a class of $\mathbb{Q}/\mathbb{Z}$ of exact order v' is $\sum_{v' | v} m_v$.

(b)⇒(a). If $C_n = (-1)^{\varsigma n} R(n)$, then $\rho(n) = (-1)^\varsigma R(n+1)/R(n)$ as rational functions. Writing $R = c \prod_x (n-x)^{\mu_x}$, $R(n+1)/R(n) = \prod_x \big((n-x+1)/(n-x)\big)^{\mu_x}$, whose zeros less poles, counted with multiplicity, add to zero in every class of $\mathbb{C}/\mathbb{Z}$. Comparing with the zeros and poles $-\theta_{\gamma,t}$ of ρ, of multiplicities s_γ, $\sum_{v' | v} m_v = 0$ for every $v' \geq 2$, and descending from the largest slope, $m_v = 0$ for every $v \geq 2$: that is (a). It does not involve k.

(a)⇒(b). Under (a), $m_v = 0$ for $v \geq 2$, hence $m_1 = 0$ by $\sum_v v m_v = 0$, and $r_W = \prod_{v \geq 2} v^{v m_v} = 1$. Every class of $\mathbb{Q}/\mathbb{Z}$ then holds as many $\theta_{\gamma,t}$ with $s_\gamma = 1$ as with $s_\gamma = -1$; pair them within classes, $\theta = \theta' + j$ with $j \in \mathbb{Z}$, and put $R_{\theta,\theta'}(n) = \Gamma(n+\theta)/\Gamma(n+\theta')$, which is $(n+\theta')_j$ or its reciprocal by 1.3(iii), a rational function with $R_{\theta,\theta'}(n+1)/R_{\theta,\theta'}(n) = (n+\theta)/(n+\theta')$. With $\tilde{R}$ the product of the $R_{\theta,\theta'}$, $\rho(n) = (-1)^\varsigma \tilde{R}(n+1)/\tilde{R}(n)$, $\varsigma \equiv |A_+| + \sum_{B_+} \epsilon_\gamma$. For $n > n_1$ the numbers $n + \theta_{\gamma,t}$ are positive, so $\tilde{R}$ has no zero or pole there, and $C_n = (-1)^{\varsigma n} R(n)$ with $R(n) = (-1)^{\varsigma(n_1+1)} C_{n_1+1} \tilde{R}(n)/\tilde{R}(n_1+1)$. As $|A_+| + \sum_{B_+} \epsilon_\gamma = p + 2\#\{\epsilon_\beta = 1\} + \sum_{B^{\geq 2}} \epsilon_\beta$, $\varsigma \equiv p + \sum_{B^{\geq 2}} \epsilon_\beta$.

The factorization. By (i) of 43.1, $W_k = W_0 g_k$, so it suffices to factor W_0. For integers b, b', $\Gamma(\pm a + b)/\Gamma(\pm a + b')$ and $\Gamma(\pm va + b)/\Gamma(\pm va)$ are rational functions of a with rational coefficients (1.3(iii)). The balance and (a) give $|A_+| - |A_-| = \#\{\epsilon_\beta = 1\} - \#\{\epsilon_\beta = -1\}$, so $p = |A_-| - \#\{\epsilon_\beta = -1\}$ as well. Matching the Gammas of A_+ with those of slope 1 below, and the Gammas of A_- with those of slope -1, leaves a rational function times $\Gamma(a)^p \Gamma(1-a)^p = \pi^p / \sin(\pi a)^p$ (1.3(v)), read as $\sin(\pi a)^{|p|}/\pi^{|p|}$ when $p < 0$; each pair β, β' with $\epsilon_\beta = v = -\epsilon_{\beta'}$, $v \geq 2$, leaves a rational function times $1/(\Gamma(va)\Gamma(1-va)) = \sin(\pi va)/\pi$. There are $|B^{\geq 2}|$ pairs, and $w = |A_+| - |B_+| = p - |B^{\geq 2}|$, which gives the display, the sign and R_k collecting the rational factors.

The residue. At $a = -n + \varepsilon$, $\sin(\pi a) = (-1)^n \sin(\pi\varepsilon)$ and $\sin(\pi va) = (-1)^{vn} \sin(\pi v \varepsilon)$, so the trigonometric factor is $(-1)^{n(\sum_{B^{\geq 2}} \epsilon_\beta - p)} \pi^w \prod_\beta \sin(\pi \epsilon_\beta \varepsilon) / \sin(\pi\varepsilon)^p$. Since $\sin(\pi x)/(\pi x)$ is an even power series in πx with rational coefficients and constant term 1, this is $(-1)^{\varsigma n} \varepsilon^{-w} \sum_{l \geq 0} \tau_l \pi^{2l} \varepsilon^{2l}$ with rational τ_l depending on the slopes and $\tau_0 = \prod_{B^{\geq 2}} \epsilon_\beta$. For $n > n_1$ the pole of W_k at $-n$ has the order w exactly, $C_n \neq 0$, and the trigonometric factor has a pole of order w there, so R_k is holomorphic at $-n$; the coefficient of ε^{-1} is the displayed sum.

The closing. The finitely many residues at $-n < c$ with $n \leq n_1$ are, by the same factorization, combinations of the $\tau_l \pi^{2l}$ with Laurent coefficients of R_k, so they lie in $\mathbb{Q}[\pi^2]$. For $n > n_1$ the residue is $\pm(-1)^{\varsigma n} r(n)$ with $r(n) = \sum_l \tau_l \pi^{2l} R_k^{(w-1-2l)}(-n)/(w-1-2l)!$, a rational function of n whose partial fractions have coefficients in $\mathbb{Q}[\pi^2]$, the poles of R_k being rational. The closing converges; when $\varsigma = 0$ its terms are $r(n)$, so $r(n) = O(n^{-2})$, and when $\varsigma = 1$, $r(n) \to 0$, so $r(n_1 + 1 + 2m) - r(n_1 + 2 + 2m) = O(m^{-2})$, and summing consecutive pairs does not change the sum. 38.32 over $\Bbbk = \mathbb{Q}(\pi^2)$, whose identities are linear in the coefficients of the partial fractions (its proof applies 37.10 to them), writes the sum over 1, the Trailmoments of the lattice inputs on the cosets of the poles at their cuts, and the differences of their index-one values, with coefficients in $\mathbb{Q}[\pi^2]$. Finally $(\mathsf{T}_{2;(1)}[x]\, \mathbb{I}_\mathbb{Z})((0,\infty)) = \pi^2/6$ by 5.17(iv) at $j = 1$. □

Theorem 43.3 (The frame bounds the clearing from below). *As stated.*

Proof. (i) As $p_h(k) \neq 0$ for $k \geq k_0$, a solution is fixed by its values at $k_0, \dots, k_0 + h - 1$, so independent solutions have independent initial vectors and $C_{k_0} \neq 0$; by 38.11, $C_{k+1} = (-1)^h \frac{p_0(k)}{p_h(k)} C_k$ with $p_0(k) \neq 0$, so $C_k \neq 0$ for every $k \geq k_0$. Then $D_k^h C_k = \det \left[D_k x_{k+l}^{(i)} \right]$ is a nonzero integer and $D_k^h |C_k| \geq 1$. By 38.12, $\log |C_k| = k \log |c| + (d_0 - d_h)(k \log k - k) + O(\log k)$, and $h \log D_k \geq - \log |C_k|$ gives the inequality. When $d_0 = d_h$ the term in $k \log k$ is absent, and the same proposition identifies $|c|$.

(ii) The coefficients of v_l and of 1 in $\sum_j p_j(k) x_{k+j} = 0$ are $\sum_j p_j(k) A_{k+j,l}$ and $- \sum_j p_j(k) B_{k+j}$, rational since $p_j \in \mathbb{Q}[k]$ and k is an integer; as $1, v_1, \dots, v_m$ are independent over $\mathbb{Q}$, all of them vanish. A D_k that clears the rows of $x_k, \dots, x_{k+h-1}$ makes the values at $k, \dots, k + h - 1$ of all $m + 1$ sequences integers, in particular those of h independent ones, and (i) applies to them. □

Definition 43.4 (The merit of rows along a ray). As stated.

Proof. $f(\alpha^\star)$ is positive and finite (38.14(i)), and $D_k \geq 1$ gives $\limsup_k \frac{1}{k} \log D_k \geq 0$, so the merit lies in $[-\infty, - \log f(\alpha^\star)]$. □

Theorem 43.5 (The merit decides the gap along a ray). *As stated.*

Proof. (i) By 38.14(i), $0 < f \leq f(\alpha^\star)$ on the orthant and $\langle 1 \rangle_k = \int_{y_{e_0}=0} f^k \omega_0$ converges and is positive for $k \geq k_1$; the origin is real, so $\omega_0 / dy = \alpha^{\mathbf{m}_0} \prod_j K_j^{-s_{0j}} \Psi_j^{-t_{0j}}$ is positive on the orthant. Hence $\langle 1 \rangle_k = \int f^{k-k_1} f^{k_1} \omega_0 \leq f(\alpha^\star)^{k-k_1} \langle 1 \rangle_{k_1}$, and $D_k \geq 1$.

(ii) If the merit is positive, choose $\eta > 0$ below it; then $D_k \leq f(\alpha^\star)^{-k} e^{-k\eta}$ for all large k, and by (i) $0 < D_k \langle 1 \rangle_k \leq e^{-k\eta} f(\alpha^\star)^{-k_1} \langle 1 \rangle_{k_1} \to 0$. With $x_k = \langle 1 \rangle_k$, 37.2 gives an irrational v_l, and for $m = 1$, $A_{k,1} \neq 0$ for all large k; then v_1 is the irrational one.

(iii) $\frac{1}{k} \log D_k \leq \frac{\log C}{k} + \log \gamma + \frac{w}{k} \log d_{\lfloor ak+b \rfloor}$. For $a > 0$, $N = \lfloor ak + b \rfloor \to \infty$ with $N/k \to a$, and $\limsup_N \frac{1}{N} \log d_N \leq c_{\mathrm{lcm}}$ (37.1), so $\limsup_k \frac{1}{k} \log D_k \leq \log \gamma + a w c_{\mathrm{lcm}}$; for $a = 0$ the last term tends to 0. The merit is then at least $- \log f(\alpha^\star) - \log \gamma - a w c_{\mathrm{lcm}}$, positive when $\gamma e^{a w c_{\mathrm{lcm}}} f(\alpha^\star) < 1$.

(iv) By 43.3(ii) and (i), $\liminf_k \frac{1}{k} \log D_k \geq \frac{1}{h} \log \frac{1}{|c|}$, so the lim sup is at least as large, and the merit is at most $- \log f(\alpha^\star) + \frac{1}{h} \log |c|$. □

Proposition 43.6 (The low end of the law). *As stated.*

Proof. (i) The law says that $\sum_i p_i(k) f^i$ lies in the relation space $\mathcal{L}$ (38.4), a finite sum $\sum r_{e,l}(k) (c_e^{(0)} + k c_e^{(1)} + \partial_{y_e}) g_{e,l}$ with $r_{e,l} \in \mathbb{C}(k)$. Integration by parts against $f^k dy$, for complex k of large real part where the integrals converge absolutely (38.3), gives $\sum_i p_i(k) \langle 1 \rangle_{k+i} = 0$ there off the poles of the $r_{e,l}$, hence identically for the meromorphic continuation of 39.34. At an integer $k \geq 1$ every $\langle 1 \rangle_{k+i}$ is a convergent integral, the walls $(k + i)\kappa_{1,S}$ being positive, and the law holds there. Near $k = 0$ the terms $i \geq 1$ are holomorphic, and by 39.34 at $j = 0$, with $j(1) = 0$ and $\mathsf{C}_0(1) = \mathrm{CT}(1) = 1$, $\langle 1 \rangle_k = V_1 k^{-(n-1)} + O(k^{-(n-2)})$ with $V_1 > 0$. So $p_0(k) \langle 1 \rangle_k$ is holomorphic at 0, which forces p_0 to vanish there to the order $n - 1$ at least, and its value at 0 is ϖV_1. The law at $k = 0$ is the low-end relation. The walls of the integral direction are integers, $\kappa_{1,S} = m_{1,S} - \sum_j (s_{1j} d_j(S) + t_{1j} d_j^*(S))$ (8.1), so V_1 is rational.

(ii) c and r exist and are rational because $p_2(k) \neq 0$ for $k \geq 1$ and $p_0, p_1, p_2, \varpi V_1$ are rational. The low-end coefficient of c is $-p_1(0) - p_2(0)\big(- p_1(0)/p_2(0) \big) = 0$ and that of r is $-p_2(0)\big(- \varpi V_1 / p_2(0) \big) = \varpi V_1$. The sequence $x_k - x_1 c_k - r_k$ solves the law on $k \geq 1$; it vanishes at $k = 1$,

and at $k=2$ it is $\big(p_2(0)x_2+p_1(0)x_1+\varpi V_1\big)/p_2(0)=0$ by the low-end relation; so it vanishes identically. $\square$

Definition 43.7 (Reflexive laws). As stated.

Proof. Let c_i be the coefficient of k^d in p_i, so the symbol is $\sigma(\varrho)=\sum_i c_i\varrho^i$ with $c_0c_h\neq 0$ (38.7). The coefficient of k^d in $p_{h-i}(-k-h+1)$ is $(-1)^d c_{h-i}$, so $(-1)^d c_{h-i}=\gamma\lambda^i c_i$, and

$$\varrho^h\sigma(\lambda/\varrho)=\sum_i c_i\lambda^i\varrho^{h-i}=(-1)^d\gamma^{-1}\sum_i c_{h-i}\varrho^{h-i}=(-1)^d\gamma^{-1}\sigma(\varrho).$$

As $\sigma(0)=c_0\neq 0$, $\varrho\mapsto\lambda/\varrho$ maps the roots of σ to roots, with multiplicities. At $h=2$ the identities at $i=0$ and $i=2$ give $c_0/c_2=(-1)^d\gamma^{-1}$ and $c_0/c_2=(-1)^d\gamma\lambda^2$, so $\gamma^2\lambda^2=1$, $\gamma=\pm\lambda^{-1}$, and the product of the roots, c_0/c_2, is $\pm\lambda$. $\square$

Theorem 43.8 (The closings read the coordinate of a reflexive law). *As stated.*

Proof. (i) By 39.36, $\sum_{i=0}^{\min(h,j)} p_i(-j)\mathsf{C}_{j-i}(1)=0$ for every $j\geq 0$. For $k\geq 1$ put $j=k+h-1\geq h$. Reflexivity, $p_i(k)=\gamma^{-1}\lambda^{-i}p_{h-i}(-k-h+1)$, gives

$$\sum_{i=0}^{h} p_i(k)\,\lambda^{k+i-1}\mathsf{C}_{k+i-1}(1)=\gamma^{-1}\lambda^{k-1}\sum_{i=0}^{h} p_{h-i}(-j)\,\mathsf{C}_{j-(h-i)}(1)=0.$$

For the low-end coefficient, reflexivity at $k=0$ gives $p_i(0)=\gamma^{-1}\lambda^{-i}p_{h-i}(-h+1)$, so

$$\sum_{i=1}^{h} p_i(0)\,\lambda^{i-1}\mathsf{C}_{i-1}(1)=\gamma^{-1}\lambda^{-1}\sum_{i'=0}^{h-1} p_{i'}(-(h-1))\,\mathsf{C}_{h-1-i'}(1)=0,$$

by 39.36 at $j=h-1$.

(ii) At $h=2$, $y_1=\mathsf{C}_0(1)=1=c_1$, and the vanishing of the low-end coefficient, $p_1(0)+p_2(0)y_2=0$, gives $y_2=-p_1(0)/p_2(0)=c_2$; both solve the law and $p_2(k)\neq 0$ for $k\geq 1$, so $y=c$, and 43.6(ii) gives the display. With $\langle 1\rangle_1=A_1v-B_1$ and r_k rational, $\langle 1\rangle_k=A_1\lambda^{k-1}\mathsf{C}_{k-1}(1)\,v-\big(B_1\lambda^{k-1}\mathsf{C}_{k-1}(1)-r_k\big)$.

(iii) With integer weights, $f^{-1}=\alpha^{-\mathbf{m}_1}\prod_j K_j^{s_{1j}}\Psi_j^{t_{1j}}$ is a Laurent polynomial with integer coefficients, and so is each power; at origin 0, $\omega_0/dy=1$, and $\mathsf{C}_j(1)=\mathrm{CT}(f^{-j})\in\mathbb{Z}$. The coefficient is $a^{k-1}\mathsf{C}_{k-1}(1)/b^{k-1}$; as $\gcd(a,b)=1$, its reduced denominator is $b^{k-1}/\gcd\big(b^{k-1},a^{k-1}\mathsf{C}_{k-1}(1)\big)=b^{k-1}/\gcd\big(b^{k-1},\mathsf{C}_{k-1}(1)\big)$. $\square$

Corollary 43.9 (The merit of a reflexive ray of order two). *As stated.*

Proof. The ray has origin 0, real, and $\kappa_{1,S}>0$, so Definition 43.4 applies with $m=1$, $v_1=\langle 1\rangle_1$, $A_{k,1}=\lambda^{k-1}\mathsf{C}_{k-1}(1)$ and $B_k=-r_k$. A clearing D_k makes $D_kA_{k,1}$ an integer, so by 43.8(iii) the integer b^{k-1}/g_k, $g_k=\gcd(b^{k-1},\mathsf{C}_{k-1}(1))$, divides D_k, and $\frac{1}{k}\log D_k\geq\frac{k-1}{k}\log b-\frac{1}{k}\log g_k$. Taking the upper limit, $\limsup_k\frac{1}{k}\log D_k\geq\log b-\liminf_k\frac{1}{k}\log g_k$, which is the bound. $\square$

Proposition 43.10 (The hinge closing as a row over the room). *As stated.*

Proof. (i) By 19.21(i) the closed value is the absolutely convergent sum of the residues, and grouping them by n gives $\sum_n \langle \Phi_n, \mathcal{X}_n \rangle$. Then $\langle \Phi_n, \mathcal{X}_n \rangle = \sum_i \chi_i \langle \Phi_n, \mathbf{c}_i(n) \rangle$, and a finite sum of absolutely convergent series may be summed term by term.

(ii) By 19.21(ii) the two lattices of the level d meet exactly when $2\delta^d \in \mathbb{Z}$, so otherwise every pole is simple and the residue at $\sigma^d = \pm\delta^d - n$ is a coefficient times the room period there. The sequence $\sum_i x_i^{\pm} c_i^{\pm}(n)$ solves the recurrence and agrees with $x^{\pm}$ at $0, \dots, h_{\pm} - 1$; as $p_{h_{\pm}}^{\pm}(n) \neq 0$ for $n \geq 0$, the two agree for every n. The $c_i^{\pm}$ are computed from rational initial values by the recurrence, so they are rational when the coefficients are. So $\mathcal{X}_n = \sum_i x_i^{+} \big(c_i^{+}(n), 0\big) + \sum_i x_i^{-} \big(0, c_i^{-}(n)\big)$, and (i) applies.

(iii) For $2\delta^d \in \mathbb{Z}$ the lattices $\delta^d - \mathbb{N}$ and $-\delta^d - \mathbb{N}$ are both contained in $|\delta^d| - \mathbb{N}$, and by 19.21(ii) the residue at a common point carries the room period and its derivative in σ^d, at a simple point the room period alone. The room period converges at the points of the lattice (19.21(i)), and near them it is an absolutely convergent integral over the simplex of a function holomorphic in the level shares (8.7), so it is holomorphic in the even share there. The state $U_n(\sigma) = (x_n(\sigma), \dots, x_{n+h-1}(\sigma))$ satisfies $U_{n+1}(\sigma) = \mathbf{A}(n, \sigma) U_n(\sigma)$ with the companion matrix of the recurrence, whose entries $-p_i(n, \sigma)/p_h(n, \sigma)$ are regular at $\sigma = \sigma_0$ for $n \geq 0$. By 37.17 with $\varepsilon = \sigma - \sigma_0$ and $J = 1$, $U_{n+1,0} = \mathbf{A}_0(n) U_{n,0}$ and $U_{n+1,1} = \mathbf{A}_0(n) U_{n,1} + \mathbf{A}_1(n) U_{n,0}$, so $(U_{n,0}, U_{n,1})$ is a product of block-triangular matrices, which depend on the recurrence alone, applied to $(U_{0,0}, U_{0,1})$, the $2h$ initial data. This writes $\mathcal{X}_n$ as in (i), which applies when the resulting sums converge absolutely.

With the bunch and the room exchanged, 19.21(i) closes on the lattices of the level r with the opposite sign, and the same argument applies. □

Definition 43.11 (Critical primes). As stated.

Proof. A native gauge lies in X_F, so every letter is nonzero there, and $f(\alpha_c) \in \Bbbk^{\times}$ since the weights and the coordinates lie in $\Bbbk$; its valuation at $\mathfrak{p}$ is defined. □

Theorem 43.12 (The letters degenerate at a critical prime). *As stated.*

Proof. Let $\mathcal{O}$ be the local ring of $\Bbbk$ at $\mathfrak{p}$, a discrete valuation ring, with a uniformizer $\varpi_{\mathfrak{p}}$, and $v = v_{\mathfrak{p}}$. The letters have coefficients in $\mathcal{O}$ and the coordinates of α_c are units, so every $L(\alpha_c)$ and every $\partial_e L(\alpha_c)$ lies in $\mathcal{O}$, and $L(\alpha_c) \neq 0$. Since $\alpha_c^{\mathbf{m}_1}$ is a unit, $v(f(\alpha_c)) = -\sum_L w_L v(L(\alpha_c)) < 0$, so the largest valuation $v_{\max}$ is positive, and the letters of S vanish at $\bar{\alpha}_c$. The native gauge has $c_e^{(1)} = \partial_{y_e} \log f = 0$ for $e \neq e_0$ (38.4, 38.2(ii)), that is $m_{1,e} = \sum_L w_L \, \alpha_e \partial_e L / L$ at α_c; by Euler's identity for the homogeneous letters, $\sum_e \alpha_e \partial_e L = (\deg L) L$, and the balance $m_{1,\mathcal{E}} = \sum_L w_L \deg L$ of a direction (f has degree 0), the same holds at $e = e_0$. Write $L(\alpha_c) = \varpi_{\mathfrak{p}}^{v_L} u'_L$ with $u'_L \in \mathcal{O}^{\times}$ and multiply the equation of the mark e by $\varpi_{\mathfrak{p}}^{v_{\max}}$:

$$\sum_L w_L \, \alpha_{c,e} \, \partial_e L(\alpha_c) \, \varpi_{\mathfrak{p}}^{v_{\max} - v_L} u_L'^{-1} = m_{1,e} \, \varpi_{\mathfrak{p}}^{v_{\max}}.$$

Every term lies in $\mathcal{O}$; modulo $\mathfrak{p}$ the right side and the terms with $v_L < v_{\max}$ vanish, and reduction commutes with ∂_e. Dividing by the unit $\bar{\alpha}_{c,e}$ gives (i) with $u_L = u_L'^{-1}$. Under the hypothesis of (ii) every coefficient $\overline{w_L u_L}$ is nonzero, so the gradients of the reduced letters of S at $\bar{\alpha}_c$ satisfy a linear relation with all coefficients nonzero: for one letter its gradient vanishes at a point of its zero set, which is singular there, and for several the gradients are linearly dependent, whereas smooth hypersurfaces meeting transversally have independent gradients. □

Proposition 43.13 (Critical primes and the symbol). *As stated.*

Proof. (i) $c_h^{h-1}\sigma(\lambda) = \sum_j c_j c_h^{h-1-j}(c_h\lambda)^j$ is a monic polynomial with integer coefficients in $c_h\lambda$, which vanishes at a root.

(ii) If $p \nmid c_h$, c_h is a unit at every prime $\mathfrak{P}$ of K above p and $\lambda = c_h\lambda/c_h$ has $v_{\mathfrak{P}}(\lambda) \geq 0$ by (i). Conversely let $p \mid c_h$ and let $\mathfrak{P}$ be a prime above p. If every root had $v_{\mathfrak{P}} \geq 0$, the elementary symmetric functions of the roots, $\pm c_{h-j}/c_h$, would be $\mathfrak{P}$-integral, so $v_{\mathfrak{P}}(c_{h-j}) \geq v_{\mathfrak{P}}(c_h) > 0$ for every j, and p would divide every coefficient, against their coprimality. So some root has negative valuation at $\mathfrak{P}$.

(iii) Under the hypothesis, a root $\lambda = f(\alpha_c)$ with $v_{\mathfrak{P}}(\lambda) < 0$ at a prime $\mathfrak{P}$ above p makes $\mathfrak{P}$ a critical prime of α_c (43.11 with $\Bbbk = K$), and conversely; (ii) gives the equivalence. When p_0 and p_h have the largest degree d, c_0 and c_h are their leading coefficients (38.7), and c_0/c_h is the quotient c of 38.11. □

50.43 Chapter 44: relations and separation

Proposition 44.4 (A finite matrix of mark relations). *As stated, for several letters* $D_1, \dots, D_h$.

Proof. In the coordinate x_i, with the other coordinates as room and the room density $\prod_{l\neq i} x_l^{a_l-1}(1-x_l)^{b_l-1}$, 35.10(a) applies to the letters D_k, positive on the closed box, at the exponents p_k+1, and to the polynomial AD. With $\partial_i D = \sum_k \partial_i D_k \prod_{k'\neq k} D_{k'}$ its expression is

$$x_i(1-x_i)(D\,\partial_i A + A\,\partial_i D) + \big(a_i - (a_i+b_i)x_i\big)AD - x_i(1-x_i)A\sum_k (p_k+1)\,\partial_i D_k \prod_{k'\neq k} D_{k'}$$
$$= D\big[x_i(1-x_i)\,\partial_i A + \big(a_i-(a_i+b_i)x_i\big)A\big] - x_i(1-x_i)\,A\sum_k p_k\,\partial_i D_k \prod_{k'\neq k} D_{k'} = \mathrm{mr}_i(A),$$

and the read is the stated integral. At $A = x^\beta$, $x_i(1-x_i)\partial_i x^\beta + (a_i-(a_i+b_i)x_i)x^\beta = \big((\beta_i + a_i) - (\beta_i + a_i + b_i)x_i\big)x^\beta$, and $x_i(1-x_i)x^\beta \sum_k p_k \partial_i D_k \prod_{k'\neq k} D_{k'} = (1-x_i)x^\beta \sum_\gamma D_\gamma^{(i)} x^\gamma$; expanding $D = \sum_\gamma D_\gamma x^\gamma$ gives the formula. Its coefficients are rational in (a_i, b_i) over the rational coefficients of the D_k and the p_k, so for a degree bound the vectors $\mathrm{mr}_i(x^\beta)$ form a finite matrix, rational at rational a_i, b_i; by linearity a numerator $\sum_i \mathrm{mr}_i(A_i)$ has the read 0. With one letter, $D_\gamma^{(i)} = p\gamma_i D_\gamma$, the formula of the reference. □

Proposition 44.11 (The critical polynomial block). *As stated, at every order* $k \geq 1$.

Proof. For $R(u) = P(2u)$, $R(\frac{1}{2}) = P(1)$ and Q_P is the polynomial $(R(u) - R(\frac{1}{2}))/(1-2u)$, so 36.4 at the order k gives the display. $Q_P^{(2k-1)}$ has rational coefficients and the moments of $X = \frac{1}{2} + iY$ are rational (36.2(iii)), so $h(P) \in \mathbb{Q}$. The value of $c + \mathrm{crit}_k[P(2u)]$ is $\big(c + h(P)\big) + (2^{2k+1} - 1)P(1)\,(\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$; the coordinate map is onto $\mathbb{Q}^2$, the constant c giving the first coordinate and a constant P, for which $Q_P = 0$, the second; and $a + b\,(\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = 0$ with $(a,b) \in \mathbb{Q}^2$ not zero forces $b \neq 0$ and $(\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -a/b$. At the cut N, $(\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((N,\infty)) = (\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2k+1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,N])$, a rational head. □

Theorem 44.16 (Completeness along a ray). *As stated.*

Proof. (i) is Theorem 39.57: the closings, the values and the expansion at the native gauge have one annihilator, and when the values vanish their continuation in k vanishes identically. $\mathrm{Ann}(V_{\mathsf{C}})$ is a submodule (Theorem 39.4(ii)), and by Corollary 39.46 it is 0 exactly when the closings vanish

on no nonzero submodule, which holds on an irreducible submodule on which they are not zero. The closings are among the proved relations of Definition 44.1.

(ii) The submodule generated by m is the $\mathbb{C}(k)$-span of the $\mathrm{Sh}^i m$, $i \in \mathbb{Z}$, of dimension $d \le \dim \mathfrak{M}$; so $m, \mathrm{Sh}\, m, \dots, \mathrm{Sh}^d m$ are dependent over $\mathbb{C}(k)$, and since $\mathfrak{M}$, the shift and m are defined over $\mathbb{Q}$ the dependence can be taken with $q_i \in \mathbb{Q}[k]$. If $q_0 = 0$ apply Sh^{-1} and shift the coefficients; if then $q_d = 0$, the relation has smaller order, against the minimality of d (the elements $m, \dots, \mathrm{Sh}^{d-1} m$ are independent, otherwise the span of all the shifts would have dimension below d). So $q_0 q_d \ne 0$. The closings are a solution (Theorem 39.33): V_{C} is $\mathbb{C}(k)$-linear and $V_{\mathsf{C}}(\mathrm{Sh}\, g)(k) = V_{\mathsf{C}}(g)(k+1)$ at the integers where both sides are defined. Applying V_{C} to the dependence gives the recurrence at every integer k with $k + d \le -j(m)$. The closings of a rational insertion are constant terms of Laurent polynomials with rational coefficients (Definition 39.30), so they are rational. Below the integer zeros of q_0 and q_d the recurrence determines $V_{\mathsf{C}}(m)(k)$ from the d values above it and conversely, so vanishing at d consecutive integers there propagates to every integer below them, and $V_{\mathsf{C}}(m) = 0$ as a germ at $-\infty$; by (i) this is the vanishing of the values. Two words have equal values exactly when their difference has the values 0. □

Lemma 44.17 (A separating generator). *As stated.*

Proof. Let $\Lambda = c_0 + \sum_i c_i v_i + cv$ with integers of height H and $c \ne 0$; for $c = 0$ the measure μ applies. For every n,

$$D_n\big(A_n\Lambda - cL_n\big) = D_n\Big(A_n c_0 + cB_{n,0} + \sum_{i=1}^{j} \big(A_n c_i + cB_{n,i}\big) v_i\Big)$$

is an integer linear form in $1, v_1, \dots, v_j$ of height at most $2He^{(h+d)n+o(n)}$. A nonzero integer form of height below H_0 has a value bounded away from 0, there being finitely many and the numbers $1, v_1, \dots, v_j$ being independent; so for large n every nonzero such form has modulus at least $(2He^{(h+d)n+o(n)})^{-\mu}$.

Independence. If $\Lambda = 0$ the form is $-cD_nL_n$, which is not 0, so its coefficients are not all 0, and $|c|D_n|L_n| \ge (2He^{(h+d)n+o(n)})^{-\mu}$; but $|c|D_n|L_n| \le |c|e^{(d-F)n+o(n)}$, and since $F - d > \mu(h+d)$ the two bounds contradict each other for large n.

Measure. If the form vanishes as a number, its coefficients vanish, since $1, v_1, \dots, v_j$ are independent; then $A_n c_0 + cB_{n,0} = 0$ and $A_n c_i + cB_{n,i} = 0$, so the row $(A_n, B_{n,0}, \dots, B_{n,j})$ is (A_n/c) times $(c, -c_0, -c_1, \dots, -c_j)$, and $A_n \ne 0$ because $L_n \ne 0$. Consecutive rows are not proportional, so at n or at $n+1$ the form is a nonzero integer form, and there

$$D_n|A_n|\,|\Lambda| \;\ge\; |D_n(A_n\Lambda - cL_n)| - |c|D_n|L_n| \;\ge\; \big(2He^{(h+d)n+o(n)}\big)^{-\mu} - He^{(d-F)n+o(n)}.$$

Let n be the least integer with $He^{(d-F)n+o(n)} \le \frac{1}{2}(2He^{(h+d)n+o(n)})^{-\mu}$; taking logarithms, $(F - d - \mu(h+d))\, n \ge (1+\mu)\log H + O(1) + o(n)$, so $n = (1+\mu)\log H/(F - d - \mu(h+d)) + o(\log H)$, and the inequality holds at $n+1$ as well. With $D_n|A_n| \le e^{(h+d)n+o(n)}$,

$$|\Lambda| \;\ge\; \tfrac{1}{2}(2H)^{-\mu} e^{-\mu(h+d)n - o(n)} e^{-(h+d)n - o(n)} = \tfrac{1}{2}(2H)^{-\mu} e^{-(1+\mu)(h+d)n - o(n)},$$

which is at least $H^{-\mu'}$ for all large H. □

Theorem 44.18 (Separating generators in turn). *As stated.*

Proof. Induction on j with Lemma 44.17. The number 1 alone has the measure $\mu_0 = 0$: a nonzero integer has modulus at least $1 = H^0$. If $1, \mathrm{ev}(w_1), \dots, \mathrm{ev}(w_{j-1})$ are independent with the measure μ_{j-1}, the separating generator of $\mathrm{ev}(w_j)$ with $F_j > d_j + \mu_{j-1}(h_j + d_j)$ makes $1, \mathrm{ev}(w_1), \dots, \mathrm{ev}(w_j)$ independent with the measure μ_j. At $j = s$ the values of the representatives are independent over $\mathbb{Q}$, so the block is complete (Proposition 44.8); a word of value zero then lies in the image of the relation matrix of the block, and its certificate is a finite derivation (Definition 44.7, Theorem 44.9). □

50.44 Chapter 45: the content and its coaction

Every identity proved below between admitted words is a proved relation, so it lies in the relation ideal $\mathfrak{I}$ (44.1) and holds between the classes in $\mathfrak{W}/\mathfrak{I}$; in particular the words $\zeta = e^{2\pi i r/M}$ multiply as the roots of unity do, by the functional equation of the exponential, and a constant factor ζ in front of a trail is a factor of its density, by linearity.

Definition 45.1 (The content). As stated.

Proof. For $\nu_d \geq 2$ the trail converges absolutely: its terms are bounded by $\prod_i n_i^{-\nu_i}$, and $\sum_{0<n_1<\cdots<n_d} \prod_i n_i^{-\nu_i} \leq \sum_{n_d} (1+\log n_d)^{d-1} n_d^{-2} < \infty$; so the limit of the heads is the Trailmoment. For $\nu_d = 1$ and $e^{2\pi i a_d} \neq 1$ the limit exists by 5.27. The data $(\boldsymbol{\nu}, \mathbf{a})$ are finite and rational, so the trails and the words ζ are admitted words, and the spans are defined. □

Proposition 45.2 (The content is an algebra). *As stated.*

Proof. (ii) For an integer $N \geq 1$ let $H_N(T)$ be the head of T over $\{0 < y_1 < \cdots < y_d \leq N\}$. The product $H_N(T)H_N(T')$ is the finite sum, over pairs of increasing tuples $0 < n_1 < \cdots < n_d \leq N$ and $0 < n'_1 < \cdots < n'_{d'} \leq N$, of $\prod_i e^{2\pi i a_i n_i} n_i^{-\nu_i} \prod_j e^{2\pi i a'_j n'_j} {n'_j}^{-\nu'_j}$. The distinct values among the n_i and n'_j, in increasing order $m_1 < \cdots < m_e$, and the positions of the points of each tuple among them give a surjection ϕ, increasing on each part; conversely ϕ and $m_1 < \cdots < m_e$ give back the pair. The term is $\prod_r e^{2\pi i (\sum_{\phi(x)=r} a_x) m_r} m_r^{-\sum_{\phi(x)=r} \nu_x}$, the term of T_ϕ at $(m_r)_r$. So $H_N(T)H_N(T') = \sum_\phi H_N(T_\phi)$. Every T_ϕ is a trail of level M: its frequencies lie in $\frac{1}{M}\mathbb{Z}$, and since ϕ is onto and increasing on each part, its last point holds the last point of T or of T'; if it holds only one of them it has that trail's last index and frequency, and if both, its index is at least 2. As $N \to \infty$ every head converges (45.1), and $TT' = \sum_\phi T_\phi$. The depth e lies between $\max(d, d')$ and $d + d'$ and the indices add to $|\boldsymbol{\nu}| + |\boldsymbol{\nu}'|$.

(i) and (iii). 1 is the word $\zeta = 1$. At level 1 the frequencies are integers, so the trails of depth one of level 1 are the $(\mathsf{T}_{k;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ with $k \geq 2$, the index one being excluded by $e^{2\pi i a_1} = 1$. For $\zeta, \zeta' \in \mu_M$, $(\zeta T)(\zeta' T') = \zeta\zeta' \sum_\phi T_\phi$ by (ii), with $\zeta\zeta' \in \mu_M$, so $\mathcal{C}^{(M)}$ is closed under products, with weights adding, and it contains every product of the $(\mathsf{T}_{k;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$. When $M \mid M'$, $\frac{1}{M}\mathbb{Z} \subseteq \frac{1}{M'}\mathbb{Z}$ and $\mu_M \subseteq \mu_{M'}$, so $\mathcal{C}^{(M)} \subseteq \mathcal{C}^{(M')}$; as $\mathcal{C}^{(M)}$ and $\mathcal{C}^{(M')}$ both lie in $\mathcal{C}^{(MM')}$, the union $\mathcal{C}$ is an algebra. □

Proposition 45.3 (Cosets, cuts and index one). *As stated.*

Proof. (i) *Cosets.* Put $n_i = My_i$, so that $y_i \in b_i + \mathbb{Z}$ exactly when the integer n_i is congruent to Mb_i modulo M, and the indicator of that congruence is $\frac{1}{M}\sum_{s=0}^{M-1} e^{2\pi i s(n_i - Mb_i)/M}$ (the lattice

relation of 5.12, read on one coset). Then $y_i^{-\nu_i} = M^{\nu_i} n_i^{-\nu_i}$ and $e^{2\pi i a_i y_i} = e^{2\pi i (a_i/M) n_i}$, and the heads of the trail up to N' are, term by term,

$$\sum_{\mathbf{s}\in\{0,\dots,M-1\}^d} M^{|\boldsymbol{\nu}|-d} \prod_i e^{-2\pi i s_i b_i} \sum_{MN<n_1<\cdots<n_d\le MN'} \prod_i e^{2\pi i \frac{a_i+s_i}{M} n_i}\, n_i^{-\nu_i}.$$

Here $e^{-2\pi i s_i b_i} = e^{-2\pi i s_i (Mb_i)/M} \in \mu_M$, and the frequencies $(a_i+s_i)/M$ lie in $\frac{1}{MM'}\mathbb{Z}$. If $\nu_d = 1$, then $a_d \notin \mathbb{Z}$, so $(a_d+s_d)/M \notin \mathbb{Z}$: every inner sum is the head of a trail on $\mathbb{Z}^d$ at the cut $c = MN \in \mathbb{N}$ whose last index and frequency satisfy the condition of 45.1, and the trail is the finite combination of their limits.

Cuts. For data $D = (\nu_i, a_i'')_{i\le d}$ on $\mathbb{Z}^d$ let $T_c(D)$ be the trail at the cut $c \in \mathbb{N}$, read as the limit of its heads, $T_c(\varnothing) = 1$, and $D_{>k}$ the last $d-k$ data. Splitting the points $0 < n_1 < \cdots < n_d$ by the number k of them at most c,

$$T_0(D) = \sum_{k=0}^{d} h_k(D)\, T_c(D_{>k}), \qquad h_k(D) = \sum_{0<n_1<\cdots<n_k\le c} \prod_{i\le k} e^{2\pi i a_i'' n_i} n_i^{-\nu_i},$$

first for the heads and then in the limit. So $T_c(D) = T_0(D) - \sum_{k\ge1} h_k(D) T_c(D_{>k})$, and by induction on the depth $T_c(D)$ is a polynomial in the finite sums $h_k(D_{>l})$ times 1 or a trail $T_0(D_{>l})$, which keeps the last data of D and so is a trail of level MM'. Each h_k is a finite sum of rational multiples of roots of unity in $\mu_{MM'}$, a combination of the words ζ by linearity; with 45.2 the class lies in $\mathcal{C}^{(MM')}$, and the value is as stated. A head of the trail is a finite sum of terms $e^{2\pi i \sum_i a_i y_i} \prod_i y_i^{-\nu_i}$ with $a_i y_i \in \frac{1}{MM'}\mathbb{Z}$, a rational multiple of an element of $\mu_{MM'}$.

(ii) By 5.2, $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{b+\mathbb{Z}})((N,X]) - \log(X-N) \to (\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{b+\mathbb{Z}})((N,\infty))$ as $X\to\infty$, and $\log(X-N) - \log(X-N') \to 0$, so the difference D of the two index-one values is the limit of $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{b+\mathbb{Z}})((N,X]) - (\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{b'+\mathbb{Z}})((N',X])$. With $n = My$ and the indicator above,

$$(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{b+\mathbb{Z}})((N,X]) = \sum_{s=0}^{M-1} e^{-2\pi i s b} \sum_{MN<n\le MX} \frac{e^{2\pi i s n/M}}{n}.$$

In the difference the terms $s=0$ leave the finite rational sum of $1/n$ between MN and MN', with its sign. For $s\neq0$, $\sum_{MN<n\le MX} e^{2\pi i s n/M}/n$ is the head up to MX of the trail T_s of level M of depth one, index 1 and frequency s/M, with $e^{2\pi i s/M} \neq 1$, less the finite sum over $0<n\le MN$. So $D = \sum_{s=1}^{M-1} \big(e^{-2\pi i s b} - e^{-2\pi i s b'}\big) T_s$ plus finite sums of rational multiples of roots of unity in μ_M, and $e^{-2\pi i s b} \in \mu_M$ as $Mb \in \mathbb{Z}$. □

Definition 45.4 (Chains). As stated.

Proof. No letter lies on the open segment, so the integrand is continuous on the open simplex, and its only possible singularities on the closure are at $t_i \in \{0,1\}$; the convergence is 45.6(i). □

Proposition 45.5 (The content as chains). *As stated.*

Proof. (i) is 5.27 with $e^{2\pi i a_i} \in \mu_M$: the letters c_i^{-1} lie in μ_M, the first letter is $c_1^{-1} \neq 0$, the last is 0 when $\nu_d \ge 2$ and $c_d^{-1} = e^{-2\pi i a_d} \neq 1$ when $\nu_d = 1$, and no point of $\{0\}\cup\mu_M$ lies on the open segment from 0 to 1.

(ii) The ratios c_i/c_{i+1} lie in μ_M, so frequencies $a_i' \in \frac{1}{M}\mathbb{Z}$ with $e^{2\pi i a_i'} = c_i/c_{i+1}$ exist, and $e^{2\pi i (a_i' + \cdots + a_d')} = c_i/c_{d+1} = c_i$. As $a_1 \neq 0$, $j_1 = 1$, and the word of (i) for the data (ν_i, a_i'), the blocks

$(c_i^{-1}, 0^{\nu_i - 1})$, is $a_1, \dots, a_w$. If $\nu_d = 1$ then $j_d = w$ and $e^{2\pi i a'_d} = c_d = a_w^{-1} \neq 1$, so the trail is of level M, and (i) gives the identity.

(iii) The values of $\mathcal{C}^{(M)}$ are the $\mathbb{Q}$-span of the ζ and the ζT; the $\mathbb{Q}$-span of μ_M is $\mathbb{Q}(\mu_M)$, and by (i) and (ii) the values of the trails of level M are, up to sign, exactly the chains described, the weight $|\boldsymbol{\nu}|$ of a trail being the number w of letters of its chain. □

Proposition 45.6 (Chains with an end at zero). *As stated.*

Proof. (i) Write $\phi_i(t) = \gamma'(t)/(\gamma(t) - a_i)$. As no letter lies on the open segment, $|\phi_i(t)| \leq C/t$ if $a_i = a_0$, $|\phi_i(t)| \leq C/(1-t)$ if $a_i = a_{w+1}$, and $|\phi_i| \leq C$ otherwise. Split the simplex by the number k of the t_i below $\frac{1}{2}$: the part is a product of $\{0 < t_1 < \dots < t_k < \frac{1}{2}\}$ and $\{\frac{1}{2} \leq t_{k+1} < \dots < t_w < 1\}$, on which the factors singular at the other end are bounded. On the first, put $G_j(t) = \int_{0<t_1<\dots<t_j<t} \prod_{i \leq j} |\phi_i(t_i)|\, dt$ for $t \leq \frac{1}{2}$, where $|\phi_i(s)| \leq C(1 + 1/s)$; since $a_1 \neq a_0$, $G_1(t) \leq Ct$, and if $G_{j-1}(s) \leq C_{j-1} s$ then $G_j(t) \leq \int_0^t C_{j-1} s\, C(1+1/s)\, ds \leq C_j t$; so the first factor is finite. The second is the same after $t \mapsto 1 - t$, with $a_w \neq a_{w+1}$. So the integral of the modulus is finite.

(ii) For $\tilde{\gamma} = \lambda\gamma + \eta$, $\tilde{\gamma}'(t)/(\tilde{\gamma}(t) - \lambda a_i - \eta) = \gamma'(t)/(\gamma(t) - a_i)$, and the open segment is mapped onto the open segment of the new ends.

(iii) The segment from a_{w+1} to a_0 is $\tilde{\gamma}(t) = \gamma(1-t)$, with $\tilde{\gamma}' = -\gamma'$; the substitution $t_i = 1 - t'_{w+1-i}$ maps the simplex onto itself, and each of the w factors changes sign.

(iv) For $s \in \mu_M$, (ii) with $\lambda = s^{-1}$ gives $\mathrm{I}(0; a_1, \dots, a_w; s) = \mathrm{I}(0; a_1/s, \dots, a_w/s; 1)$, with letters in $\{0\} \cup \mu_M$, first letter $a_1/s \neq 0$ and last letter $a_w/s \neq 1$. For a chain from s to 0, (iii) gives $(-1)^w$ times a chain from 0 to s whose first letter is $a_w \neq 0$ and whose last letter is $a_1 \neq s$, and the first case applies. 45.5(ii) and (iii) place the value in the values of $\mathcal{C}^{(M)}$. □

Definition 45.7 (Symbols of chains). As stated.

Proof. The variables are the formal chains of weight at least one with distinct ends; the expressions with no letter or with equal ends are not variables, so assigning them 1 and 0 involves no relation among the variables. The symbol of a trail depends on the frequencies only through the c_i, which do not change when a frequency moves by an integer, as the trail does not; and the realization converges by 45.6(i), no point of $\{0\} \cup \mu_M$ lying on the open segment between 0 and a root of unity. □

Definition 45.8 (The cutting rule). As stated.

Proof. $\mathfrak{S}_M$ is a polynomial algebra on the formal chains, so a homomorphism is fixed by arbitrary values on them; the right side of the display is an element of $\mathfrak{S}_M \otimes \mathfrak{S}_M$, its degenerate entries read by the conventions of 45.7. The rotation ρ_λ and the reversal map formal chains to formal chains, up to sign, keeping the ends distinct, and the conventions to the conventions; $\rho_{\lambda^{-1}}$ and the reversal itself are their inverses. □

Theorem 45.9 (The cutting rule is a coaction). *As stated.*

Proof. All maps in (i) and (iii) are homomorphisms of algebras, so it suffices to compare them on a formal chain $x = \mathrm{I}^{\mathfrak{s}}(a_0; a_1, \dots, a_w; a_{w+1})$. For a set $U \subseteq \{1, \dots, w\}$ the *gaps* of U are the pairs $t < t'$ of consecutive elements of $U \cup \{0, w+1\}$; for $T \subseteq S$ put

$$\tau(T, S) = \mathrm{I}^{\mathfrak{s}}(a_0; a_T; a_{w+1}) \otimes \prod_{(t,t') \text{ gap of } T} \mathrm{I}^{\mathfrak{s}}\big(a_t; a_{S \cap (t,t')}; a_{t'}\big) \otimes \prod_{(s,s') \text{ gap of } S} \mathrm{I}^{\mathfrak{s}}\big(a_s; a_{(s,s')}; a_{s'}\big),$$

with $a_{(s,s')}$ the letters strictly between the positions s and s', the degenerate entries read by the conventions.

First, for any pair of ends and letters, the display of 45.8 gives Δ of the corresponding expression even when it is not a formal chain. With no letter the expression is 1, and the display has the single term $1 \otimes 1 = \Delta 1$. With equal ends and at least one letter the expression is 0; in the display every term with a kept letter has a left factor with equal ends, which is 0, and the term with no kept letter has the right factor equal to the expression itself, which is 0; so the display gives $0 = \Delta 0$.

(i) $(\Delta \otimes \mathrm{id})\Delta x = \sum_S \Delta\, \Gamma^{\mathfrak{s}}(a_0; a_S; a_{w+1}) \otimes \prod_{\text{gaps of } S}(\cdots)$, and the display for the chain of the letters a_S keeps the letters of $T \subseteq S$ and reads the letters of S between consecutive kept ones: the sum is $\sum_{T \subseteq S} \tau(T, S)$. Next, $(\mathrm{id} \otimes \Delta)\Delta x = \sum_T \Gamma^{\mathfrak{s}}(a_0; a_T; a_{w+1}) \otimes \prod_{(t,t')} \Delta\, \Gamma^{\mathfrak{s}}(a_t; a_{(t,t')}; a_{t'})$, and by the remark above each factor is the display, a sum over the sets $S_{(t,t')}$ of letters kept inside the gap (t, t'). A family of such sets is the same as one set $S \supseteq T$, the middle factors are the chains of the letters of S inside the gaps of T, and the right factors are the gaps of the $S_{(t,t')}$ inside the gaps of T, which are the gaps of S: the sum is again $\sum_{T \subseteq S} \tau(T, S)$. For the counit, ε kills every formal chain, so in $(\varepsilon \otimes \mathrm{id})\Delta x$ only $S = \varnothing$ survives, with the right factor x; in $(\mathrm{id} \otimes \varepsilon)\Delta x$ a right factor contributes 1 only when it has no letter, so only $S = \{1, \ldots, w\}$ survives, with the left factor x.

(ii) The term of S has the left weight $|S|$ and the right weight $w - |S|$, the runs between kept letters together holding the letters not kept. The terms $S = \{1, \ldots, w\}$ and $S = \varnothing$ are $x \otimes 1$ and $1 \otimes x$, and every other term has $0 < |S| < w$.

(iii) Multiplying every entry by λ commutes with keeping a subsequence and with cutting out runs, so $\Delta \rho_\lambda x = (\rho_\lambda \otimes \rho_\lambda)\Delta x$. The reversal maps the term of S for x to the term of the mirror set $S^* = \{w + 1 - s : s \in S\}$ for the reversed chain: its left factor is $(-1)^{|S|}$ times the reversal of the kept chain read backwards, each run is reversed with the sign $(-1)^{\text{its length}}$, and the runs appear in the opposite order, which does not matter in the commutative algebra. The signs multiply to $(-1)^w$, the sign of ϱx, so $\Delta \varrho x = (\varrho \otimes \varrho)\Delta x$. □

Proposition 45.10 (The cutting rule on motivic chains). *As stated.*

Proof. A chain of level M is an iterated integral of the forms $dt/(t - a)$, $a \in \{0\} \cup \mu_M$, along the straight path between two of the points $\{0\} \cup \mu_M$ of $\mathbb{P}^1 \setminus (\{0, \infty\} \cup \mu_M)$ (Definition 45.4). Such iterated integrals, with tangential base points at the ends where a letter equals an end, are periods of the motivic torsor of paths of $\mathbb{P}^1 \setminus (\{0, \infty\} \cup \mu_M)$, a mixed Tate motive over $\mathbb{Z}[\mu_M, \frac{1}{M}]$ (Deligne and Goncharov), whose realizations are objects of the category of Definition 34.5; the motivic chain is the matrix coefficient of the element $\omega_{a_1} \cdots \omega_{a_w}$ of its de Rham realization against the class of the path. The unit, the vanishing for equal ends and the regularization are those of the torsor with tangential base points. The coaction on these motivic periods is Goncharov's formula in Brown's form, which is the displayed formula, the cutting rule term by term. The shuffle product, the composition of paths and the reversal hold for iterated integrals on paths of the torsor, and they are identities of motivic periods because they come from morphisms of the torsor; the formal chains are independent variables of $\mathfrak{S}_M$, so the realization is not injective. □

Definition 45.11 (The letter of an input). As stated.

Proof. The Laplace transform beyond the cut $n_0 - 1$ is $\mathcal{F}_{n_0-1}(u) = \sum_{n \geq n_0} \psi(n) e^{-un} = L_\psi(e^{-u})$ (5.4), and $L_\psi(1) = \sum_n \psi(n)$ where the series converges at 1, which is the Trailmoment at index zero (6.1). For $\psi(n) = e^{2\pi i a n}$, $n \geq 1$, $L_\psi(z) = \sum_{n \geq 1} (e^{2\pi i a} z)^n = e^{2\pi i a} z/(1 - e^{2\pi i a} z)$, with its pole at $e^{-2\pi i a}$, which is the letter c_1^{-1} of the depth-one trail at that frequency in 45.5(i). □

Proposition 45.12 (The letter of a live input). *As stated.*

Proof. (i) $p_i(\theta - i)z^n = p_i(n-i)z^n$, so

$$\sum_i z^{h-i} p_i(\theta - i) L_\psi = \sum_i \sum_{n \geq n_0} p_i(n-i)\psi(n) z^{n+h-i} = \sum_m z^{m+h} \sum_{i:\, m+i \geq n_0} p_i(m)\psi(m+i).$$

For $m \geq n_0$ the inner sum is the recurrence, zero; the finitely many m with $n_0 - h \leq m < n_0$ leave a polynomial Q of degree less than $n_0 + h$. Since θ^j is $z^j \frac{d^j}{dz^j}$ plus terms of lower order, the coefficient of $\frac{d^d}{dz^d}$ is $\sum_i z^{h-i} c_i z^d$, nonzero as some $c_i \neq 0$; for $z \neq 0$ it vanishes exactly when $\sigma(1/z) = 0$.

(ii) For large n, $p_h(n) \neq 0$, and the state $U(n) = (\psi(n), \ldots, \psi(n+h-1))$ satisfies $U(n+1) = \mathbf{A}(n)U(n)$ with the companion matrix of the recurrence, whose entries $-p_i(n)/p_h(n)$ tend to $-c_i/c_h$, as p_h has the largest degree: $\mathbf{A}(n) \to \mathbf{A}_\infty$, the companion matrix of σ/c_h, of spectral radius ϱ. For $\eta > 0$ there is a norm on $\mathbb{C}^h$ whose operator norm of $\mathbf{A}_\infty$ is at most $\varrho + \eta/2$ (a vector norm adapted to the Jordan form of $\mathbf{A}_\infty$, which exists for every square matrix); then $\|\mathbf{A}(n)\| \leq \varrho + \eta$ for $n \geq n_3$, and $\|U(n)\| \leq \|U(n_3)\|(\varrho + \eta)^{n-n_3}$, which with the finitely many earlier terms gives the bound. So L_ψ converges on $|z| < 1/(\varrho + \eta)$ for every η. By (i) it satisfies, near any point of that disc other than 0, a linear differential equation with polynomial coefficients and polynomial right side, whose leading coefficient vanishes only at 0 and at the reciprocals of the nonzero roots of σ; the solutions of such an equation continue analytically along every path on which the leading coefficient does not vanish (the existence theorem for linear differential equations with holomorphic coefficients, which applies because the coefficients are polynomials and the leading one is nonzero along the path). The cut plane Ω is simply connected and star-shaped about 0, and contains the disc; a path in Ω meets the singular points only inside the disc, at 0, where L_ψ is holomorphic, so L_ψ continues along every path in Ω, and by the monodromy theorem it defines a holomorphic function on Ω.

(iii) Let the two recurrences have orders h and h', with companion matrices $\mathbf{A}(n)$ and $\mathbf{A}'(n)$, invertible as rational matrices since their determinants are $\pm p_0(n)/p_h(n)$ and $\pm p'_0(n)/p'_{h'}(n)$. The vector $X(n) = U(n) \otimes U'(n)$ satisfies $X(n+1) = (\mathbf{A}(n) \otimes \mathbf{A}'(n))X(n)$ for large n, with an invertible Kronecker product, and the product sequence is the coordinate of $X(n)$ that pairs the first coordinates. Lemma S30 over the field $\Bbbk$ generated by the coefficients gives the recurrence of order at most hh' with nonzero extreme coefficients.

(iv) By (ii), $|\psi(n)\psi'(n)| \leq C(\varrho + \eta)^n(\varrho' + \eta)^n$, so the letter of $\psi\psi'$, the termwise product of the coefficients of L_ψ and $L_{\psi'}$, converges on $|z| < 1/(\varrho\varrho')$. By (ii), L_ψ and $L_{\psi'}$ are holomorphic on the planes cut along the rays from the reciprocals of the nonzero roots of σ and of σ'. Hadamard's multiplication theorem, which applies to two power series holomorphic on planes cut along the outward rays from finitely many nonzero points, makes the series of the termwise products holomorphic on the plane cut along the outward rays from the products of those points, the points $1/(\lambda\lambda')$. □

Proposition 45.13 (The row of a hinge closing read by letters). *As stated.*

Proof. (i) The $c_i^\pm$ solve the room's recurrence, whose last coefficient has the largest degree, so by 45.12(ii) $|c_i^\pm(n)| \leq C(\varrho^\pm + \eta)^n$; likewise $|\Phi_n^\pm| \leq C(\varrho_\Phi^\pm + \eta)^n$ for large n. With η small, $(\varrho^\pm + \eta)(\varrho_\Phi^\pm + \eta) < 1$, and the sums converge absolutely; the radius of convergence of $L_{\psi_i^\pm}$ exceeds 1, so $\Xi_i^\pm = L_{\psi_i^\pm}(1)$. 43.10(ii) gives the row.

(ii) By 45.12(iii) the product $\psi_i^\pm$ satisfies a recurrence with polynomial coefficients for large n, so by 45.12(i) its letter, up to a polynomial from the finitely many first terms, satisfies a linear

differential equation with polynomial coefficients; and 45.12(iv), applied to the tails of the two factors, gives the continuation, the finitely many first terms adding a polynomial. □

Definition 45.14 (The motivic content; cuts; separating generators). As stated.

Proof. (i) The shuffle of two words whose first letters are not 0 and whose last letters are not 1 is a sum of such words, so by the shuffle product of motivic chains (Proposition 45.10) the span is an algebra. The weight is additive under the shuffle product, which preserves the number of letters, and it is the grading of the weight filtration of the motives of Proposition 45.10, which is split for mixed Tate motives (Deligne and Goncharov). (ii) For $a \in \frac{1}{M}\mathbb{Z}\backslash\mathbb{Z}$, $\big((\mathsf{T}_{1;(1)}[x]\, e^{2\pi i a x}\mathbb{I}_{\mathbb{Z}})((0,\infty))\big)^{\mathfrak{m}} = -\mathrm{I}^{\mathfrak{m}}(0; e^{-2\pi i a}; 1)$ is the motivic logarithm of $1 - e^{2\pi i a}$, so $\big((\mathsf{T}_{1;(1)}[x]\, 2i\sin(\frac{2\pi x}{M})\,\mathbb{I}_{\mathbb{Z}})((0,\infty))\big)^{\mathfrak{m}}$ is the motivic logarithm of $(1 - e^{-2\pi i/M})/(1 - e^{2\pi i/M}) = -e^{-2\pi i/M}$, a root of unity; the Kummer motive of a root of unity is split, so this motivic logarithm is a rational multiple of the motivic period of the circle, and its period is $2\pi i\,(\frac{1}{2} - \frac{1}{M})$ (with $(\mathsf{T}_{1;(1)}[x]\, e^{2\pi i a x}\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -\log(1 - e^{2\pi i a})$ by (iv)). At level 1 the motivic periods of weight 2 are the rational multiples of $\mathbb{L}^2$, the category having no extensions of $\mathbb{Q}(0)$ by $\mathbb{Q}(1)$ or by $\mathbb{Q}(2)$ (Deligne and Goncharov, with Borel's ranks); $\big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))\big)^{\mathfrak{m}} = -\mathrm{I}^{\mathfrak{m}}(0;1,0;1)$ is one of them, and its period $(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -\frac{(2\pi i)^2}{24}$ fixes the multiple. The identity holds in $\mathcal{P}^{\mathrm{mot}}$, so also at level 2. (iii) The coaction of $\mathcal{P}^{(M)}$ has its right factors in the de Rham chains, and Brown's infinitesimal coaction reads the part with one de Rham factor of positive weight in the motivic periods modulo the circle and modulo products; it is well defined on $\mathcal{P}^{(M)}$ because the coaction is (Brown for $M = 1$; Deligne and Glanois for $M = 2, 3, 4$), and on a motivic chain it is the displayed sum, the terms of Proposition 45.10 whose product of runs has exactly one factor of positive weight, of r letters. The composition of paths, the reversal, the rotations, which are automorphisms of $\mathbb{P}^1 \setminus (\{0,\infty\} \cup \mu_M)$ that move the tangential base point at 0 by a root of unity, and the regularization write every motivic chain of level M as a polynomial in $\mathbb{L}$ and in motivic values of trails, and the terms with a factor $\mathbb{L}$ vanish modulo the circle. (iv) At $N = 1$ and $a \notin \mathbb{Z}$, $(\mathsf{T}_{1;(1)}[x]\, e^{2\pi i a x}\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -\log(1 - e^{2\pi i a})$ with the principal logarithm, by the limit of the heads (Theorem 5.27); so $-(\mathsf{T}_{1;(1)}[x]\, e^{\pi i x}\mathbb{I}_{\mathbb{Z}})((0,\infty)) = \log 2$ and $-(\mathsf{T}_{1;(1)}[x]\, 2\cos(\frac{2\pi x}{3})\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = \log|1 - e^{2\pi i/3}|^2 = \log 3$. □

Theorem 45.15 (The content is separated by its cuts and its value). *As stated.*

Proof. (i) The motivic chains of level M are periods of mixed Tate motives over $\mathbb{Z}[\mu_M, \frac{1}{M}]$ (Proposition 45.10). The motivic Galois group of that category is $\mathbb{G}_m$ acting on a prounipotent group whose Lie algebra is free on generators of degree N, as many in each degree as the dimension of the extensions of $\mathbb{Q}(0)$ by $\mathbb{Q}(N)$, and these dimensions are one exactly in the degrees in which Definition 45.14(iv) places a separating generator and zero otherwise at the levels 1 to 4 (Deligne and Goncharov, with Borel's ranks of the groups of these number rings, which apply because the category is mixed Tate over the ring of integers of $\mathbb{Q}(\mu_M)$ with M inverted; at levels $1, 2$ the real periods leave only the even powers of the circle). So the de Rham periods read modulo the circle are the graded dual of the enveloping algebra of that free Lie algebra, the shuffle algebra on letters x_N with the coproduct that cuts a word into its two ends, and after the choice of a lift of each letter of weight N whose cuts of lengths below N vanish, the motivic periods without negative powers of the circle are that shuffle algebra tensored with $\mathbb{Q}[\mathbb{L}^e]$, as an algebra and a comodule over it. Under this identification the coaction cuts a word $w = uv$ into $u \otimes v$, the circle is a constant, and D_r keeps the terms with v of weight r, read modulo shuffle products. The shuffle product adds the numbers of letters, so the classes modulo products are graded by the number of letters, and the class of a word of one letter x_r is not the class of any combination of longer words. Write

$\xi = \sum_{w,k} c_{w,k}\, w\, \mathbb{L}^{ek}$. The coefficient of $[x_r] \otimes u\,\mathbb{L}^{ek}$ in $\mathsf{D}_r\xi$ is $c_{ux_r,k}$, and the elements $u\,\mathbb{L}^{ek}$ are independent; so if every cut vanishes, $c_{w,k} = 0$ for every nonempty word w whose last letter has weight below N. A nonempty word of weight $N - ek$ whose last letter has weight N is x_N with $k = 0$, so $\xi = c\,x_N + b\,\mathbb{L}^N$. The second factors of $\mathsf{D}_r\xi$ have the weight $N - r$.

(ii) The runs of fewer than N letters of a chain of depth one $\mathrm{I}^{\mathfrak{m}}(0; \beta, 0^{N-1}; 1)$, $\beta \in \mu_M$, are of three kinds: bounded by equal ends, so 0; the letters 0^r between 0 and 1, regularized to 0; or 0^r between β and an end, whose motivic chain is $(-\log\beta)^r/r!$ read motivically (the reversal and the regularization), a rational multiple of $\mathbb{L}^r$, which is 0 in $\mathfrak{n}^{(M)}[r]$. So every cut of a chain of depth one vanishes, and so do the cuts of $\mathsf{w}_N^{\mathfrak{m}}$, a combination of such chains (Proposition 45.5(i)); in weight one there are no cuts. The values: $(\mathsf{T}_{N;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = \sum_y y^{-N} > 0$, and $\log 2, \log 3 > 0$. For N even, $\sum_y(\omega^y - \omega^{-y})y^{-N} = (\omega - \omega^2)\sum_y \chi(y)y^{-N}$ with $\omega = e^{2\pi i/3}$, $\omega - \omega^2 = i\sqrt{3}$ and $\chi(y) = (\omega^y - \omega^{-y})/(\omega - \omega^2)$, which is $1, -1, 0$ on $1 + 3\mathbb{Z}$, $2 + 3\mathbb{Z}$, $3\mathbb{Z}$; and $\sum_y(i^y - i^{-y})y^{-N} = 2i\sum_y \chi'(y)y^{-N}$ with $\chi'(y) = (i^y - i^{-y})/(2i)$, which is $1, -1, 0$ on $1+4\mathbb{Z}$, $3+4\mathbb{Z}$, $2\mathbb{Z}$. Both χ and χ' are completely multiplicative, and for $N \geq 2$ unique factorization and absolute convergence give $\sum_y \chi(y)y^{-N} = \prod_p(1 - \chi(p)p^{-N})^{-1}$, a product of positive factors, which is the stated difference of trails of lattice inputs on cosets. A nonzero real number and a nonzero imaginary number are independent over $\mathbb{R}$, so $c\,\mathrm{per}\,\mathsf{w}_N^{\mathfrak{m}} + b(2\pi i)^N = 0$ forces $c = b = 0$. In particular $\mathsf{w}_N^{\mathfrak{m}} \notin \mathbb{Q}\,\mathbb{L}^N$; with every cut of length below N zero it is $c\,x_N + b\,\mathbb{L}^N$ by (i) applied to any lift, with $c \neq 0$, and it serves as the lift of $c\,x_N$.

(iii) If the cuts of ξ vanish, $\xi = c\,\mathsf{w}_N^{\mathfrak{m}} + b\,\mathbb{L}^N$ by (i) and (ii), and a zero value gives $c = b = 0$ by (ii); conversely $\xi = 0$ has zero cuts and value. The identification of (i), with $\mathsf{w}_N^{\mathfrak{m}}$ as the lift of x_N (a rescaling of the letter), is the homomorphism: the coefficients of the words ending in x_r, $r < N$, are read from D_r and, recursively, from the cuts of the second factors, and those of x_N and $\mathbb{L}^N$ from the readout. Content words have the motivic values of their symbols, and the homomorphism is injective.

(iv) The motivic chains of level M give every motivic period of the category without negative powers of the circle (Brown for $M = 1$; Deligne for $M = 2, 3, 4$), so the homomorphism is onto; and a shuffle algebra over $\mathbb{Q}$ is the polynomial algebra on its Lyndon words (Radford's theorem, which applies because the letters are graded and the shuffle product is commutative). □

Corollary 45.16 (The values of the content and its generators). *As stated.*

Proof. By Theorem 45.15(iv) every element of $\mathcal{P}^{(M)}$ is uniquely a polynomial over $\mathbb{Q}$ in $\mathbb{L}^e$ and the $g_i^{\mathfrak{m}}$, and the period is a homomorphism of algebras that sends them to $(2\pi i)^e$ and the values of the g_i. If these values are algebraically independent, the period is injective on $\mathcal{P}^{(M)}$, so a combination of content words of value zero has motivic value zero, and Theorem 45.15(iii) decides it. A nonzero polynomial over $\mathbb{Q}$ in $\mathbb{L}^e$ and the $g_i^{\mathfrak{m}}$ is a nonzero motivic value, by the uniqueness; if its value vanishes, the relation among the values does not hold among the motivic values. □

Definition 45.17 (The separation procedure). As stated.

Proof. Each step is a finite computation in exact rational arithmetic: the trails of level M of weight k are finitely many (their indices are compositions of k, their frequencies lie in $\frac{1}{M}\mathbb{Z}/\mathbb{Z}$), the cutting rule is a finite sum, the reading of a run or of a kept chain is a finite sum over its regularization, and the rest is linear algebra over $\mathbb{Q}$. □

Theorem 45.18 (Completeness by proved relations, weight by weight). *As stated.*

Proof. The relations R_k hold for motivic values, so $V_k \to \mathcal{P}^{(M)}[k]$ is defined, and it is onto, $\mathcal{P}^{(M)}[k]$ being spanned by the motivic values of the trails of weight k (Definition 45.14(i)).

For $r < N$, $V_r/\mathfrak{v}_r \to \mathfrak{n}^{(M)}[r]$ is injective. Indeed $V_r \to \mathcal{P}^{(M)}[r]$ is injective by hypothesis; the products of positive weights in $\mathcal{P}^{(M)}[r]$ are the images of the products in V_r, by surjectivity in the lower weights; and $\mathbb{L}^e\,\mathcal{P}^{(M)}[r-e]$ is contained in the products when $r > e$ and is the image of the trails whose values are rational multiples of $(2\pi i)^e$ when $r = e$. So an element of V_r whose motivic value lies in the denominator of $\mathfrak{n}^{(M)}[r]$ differs from an element of $\mathfrak{v}_r$ by an element of the kernel, which is 0. Likewise $V_{N-r} \to \mathcal{P}^{(M)}[N-r]$ is injective.

The cut of step (2) of a trail maps, under these two injective maps, to the cut of its motivic value (Definition 45.14(iii)), the readings of step (2) being identities of motivic chains. By step (3) the cuts are linear maps on V_N compatible with these maps. Let $\xi \in V_N$ have motivic value 0. Then every cut of $\xi^{\mathfrak{m}}$ vanishes, so every cut of ξ computed in step (2) vanishes, the tensor product of two injective maps of vector spaces being injective. So ξ lies in the joint kernel of step (4), $\xi = \sum_i c_i t_i$ with t_i classes of trails whose values are independent over $\mathbb{Q}$; its value $\sum_i c_i \operatorname{per}(t_i)$ is the period of $\xi^{\mathfrak{m}} = 0$, so every $c_i = 0$ and $\xi = 0$. □

Definition 45.19 (Chains over an equation). As stated.

Proof. The module $K\langle\partial_z\rangle/K\langle\partial_z\rangle L$ has the dimension h over K, so it has finite length and, by the Jordan–Hölder theorem, its composition factors do not depend on the series. Every module of finite dimension over K with a derivation is cyclic (the cyclic vector lemma), so each factor and its dual is the module of one operator, the dual of $K\langle\partial\rangle/K\langle\partial\rangle Q$ being that of the adjoint Q^*. For a solution s of a factor, a K-linear map from the factor to the functions with $s(\partial m) = s(m)'$, the combinations over K of s of a cyclic vector and of its derivatives are the values of s, so the kernels do not depend on the operator chosen. The integrals converge, the kernels being continuous on γ. □

Proposition 45.20 (Every solution is read through chains over its equation). *As stated.*

Proof. Let $M = K\langle\partial\rangle/K\langle\partial\rangle L$ and take a composition series $0 = M_0 \subset \cdots \subset M_r = M$. Let $\mathcal{O} \subset K$ be the ring of the functions regular off S, $\Bbbk[z]$ with the inverse of the polynomial that vanishes at the finite points of S, a principal ideal domain. The classes of $1, \partial, \dots, \partial^{h-1}$ span over $\mathcal{O}$ a free module Λ of rank h that ∂ preserves, the leading coefficient of L being a unit of $\mathcal{O}$; the $\Lambda \cap M_j$ are saturated, so direct summands, and a basis $e_1, \dots, e_h$ of Λ can be chosen adapted to the series. With $\partial e_l = \sum_m A_{ml} e_m$, $A \in M_h(\mathcal{O})$ is block upper triangular, with the matrix of the factor M_j/M_{j-1} in the block j. A solution y is a K-linear map s from M to the functions with $s(\partial m) = s(m)'$, y being s of the class of 1, and $Y = (s(e_1), \dots, s(e_h))$ satisfies $Y' = YA$. The class of 1 is $\sum_l p_l e_l$ with $p_l \in \mathcal{O}$, so $y = \sum_l p_l Y_l$, and the e_l are combinations over $\mathcal{O}$ of the classes of $1, \partial, \dots, \partial^{h-1}$, so the entries of $Y(a)$ are combinations of $y(a), \dots, y^{(h-1)}(a)$, with the values at a of elements of $\mathcal{O}$ as coefficients. Write $Y = (Y_1, \dots, Y_r)$ by blocks, so that $Y_j' = Y_j A_{jj} + \sum_{i<j} Y_i A_{ij}$, and let Φ_j be the matrix whose rows are the solutions of $X' = XA_{jj}$ with $\Phi_j(a)$ the identity. A row of Φ_j is a solution of the factor j read on the images of the e_l, so its entries are combinations over K of one solution of the operator of the factor j and of its derivatives; a column of Φ_j^{-1} solves $X' = -A_{jj}X$, and its entries are the same for the dual of the factor. Variation of the constants gives

$$Y_j(z) = \Big(Y_j(a) + \int_a^z \sum_{i<j} Y_i A_{ij} \Phi_j^{-1}\Big)\Phi_j(z)$$

along γ. By induction on j every entry of Y_j is a sum of terms $c\,\mathrm{I}\,\beta$, with c an entry of a row of Φ_j and β an entry of $Y(a)$: in the integrand an entry of a row of Φ_i times $A_{ij}\Phi_j^{-1}$ is a sum of kernels, and the integral of a kernel against a chain is a chain of one more weight; multiplying by Φ_j multiplies by the entries of its rows. Then $y = \sum_l p_l Y_l$, and $\sum_l p_l$ times the entries of one row of Φ_j is a combination over K of one solution of the factor j and of its derivatives.

The factors and their duals have only regular singular points, as subquotients of a regular module and their duals, so their solutions have at b expansions of the stated form, finite sums (Fuchs's theorem). Such expansions are kept by products, and by integration along γ, termwise near b, the term $(z-b)^{-1}$ bringing one more power of $\log(z-b)$, plus a constant; so every $c_i\mathrm{I}_i$ has one, by induction on the weight. The expansions are unique and add. On the final segment write $x = -\log|z-b|$, the argument of $z-b$ being constant there: the terms of the expansion of y with $\operatorname{Re}\rho \le 0$ make a finite sum $\sum_{\rho,l} a_{\rho,l}\, e^{-\rho x}x^l$, and the others tend to 0. Let (σ, l) be the largest pair, ordered by $\sigma = -\operatorname{Re}\rho \ge 0$ and then by l, with a nonzero coefficient; divided by $e^{\sigma x}x^l$ the sum is a nonzero sum of characters $e^{-i\tau x}$, $\tau = \operatorname{Im}\rho$, plus a term that tends to 0, and a nonzero sum of characters does not tend to 0, the mean of its square modulus being the sum of the squares of the moduli of its coefficients. So if y has a limit, $(\sigma, l) = (0, 0)$, the sum is a sum of characters with a limit, hence its constant term alone, and the limit is the constant term of the expansion of y, which is $\sum_i [c_i\mathrm{I}_i]_b\beta_i$. □

Theorem 45.21 (The closing in any number of shares). *As stated.*

Proof. (i) The data are real with nonnegative exponents on the balance wall and every proper wall positive, so Theorem 15.13(i) applies with the references M_i, and $b_{\mathbf{n}} = \Gamma_{\!1}^{n}\begin{bmatrix}\mathbf{m}\\ m_{\mathcal{E}}\end{bmatrix}\mathbb{E}_{\mathrm{Dir}_{\mathbf{m}}}\big[\prod_i (M_i - L_i)^{n_i}\big]$ by Theorem 3.9. A Dirichlet moment of a polynomial with rational coefficients at rational masses is rational, $\mathbb{E}[U^{\boldsymbol\gamma}] = \prod_e (m_e)_{\gamma_e}/(m_{\mathcal{E}})_{|\boldsymbol\gamma|}$, and $0 \le M_i - L_i$ on the simplex, so $\psi(N) \in \mathbb{Q}_{\ge 0}$; grouping a convergent series of nonnegative terms by $N = |\mathbf{n}|$ keeps its sum. For $|z| < 1$, $\sum_n \frac{(w)_n}{n!} z^n (1 - L/M)^n = (1 - z + zL/M)^{-w}$, dominated by $(1-|z|)^{-w}$ since $0 \le 1 - L/M \le 1$, which gives the display. For $0 < z < 1$ the deformed letters $(1-z)M_i|u|^{g_i} + zL_i(u)$ do not vanish on the closed simplex, so the integrand vanishes on its boundary, the masses being positive, and exact forms integrate to zero; the derivatives of $P_0 L_\psi$ in z are integrals of insertions with powers of the deformed letters in their denominators, and these forms modulo exact forms make up the top twisted de Rham cohomology of the complement of the deformed letters in the torus modulo the scale, over the field $\mathbb{Q}(z)$, which is finite-dimensional (the finiteness of the twisted algebraic de Rham cohomology of a smooth affine variety, as in Theorem 38.31(i)). So $L_\psi, L'_\psi, \dots$ are dependent over $\mathbb{Q}(z)$, which is the equation. Written as $\sum_l z^l Q_l(\vartheta) L_\psi = 0$ with $\vartheta = z\frac{d}{dz}$, its coefficient of z^N is $\sum_l Q_l(N-l)\psi(N-l) = 0$ for every N, as in Proposition 45.12(i) read backwards, with nonzero extreme coefficients. For the tail, Theorem 15.13(ii) gives the rate for the partial sums over $\max_i n_i \le N$, and with p letters $\{|\mathbf{n}| \le N\} \subseteq \{\max_i n_i \le N\} \subseteq \{|\mathbf{n}| \le pN\}$, the terms being nonnegative.

(ii) $P_c(z)$ is the period of the family with the weights θz^c and $\theta z^{c'}$, positive for $z > 0$, whose walls are those of F, since walls do not see weights; so it converges and is real analytic on $(0, \infty)$, and the argument of (i), the deformed letters now being the letters with these weights, gives its equation; the equation of a period of a family over $\mathbb{Q}(z)$ has only regular singular points (Deligne's regularity theorem for the Gauss–Manin connection, the exponents being rational). On the fibre, in the integral coordinates of Proposition 18.17, the word is a product of Gammas of affine forms with integer slopes times $z^{-\lambda(\mathbf{x})}$, λ affine, and along every free coordinate the slopes of the Gammas of each letter sum to zero, its share sum being fixed. Close the coordinates in turn by Theorem 4.5,

each toward the side where λ decreases; off finitely many hyperplanes of (c, c') the slope of λ is nonzero at every step, and then the exponent of z increases along every lattice direction of the poles crossed. A residue replaces one Gamma by $(-1)^j/(|u|\, j!)$, u its slope, and substitutes the pole into the others, whose slopes in the remaining coordinates again sum to zero for each letter; where families of poles coincide the residue takes Laurent coefficients (Proposition 5.14), which bring the powers of $\log z$ and the Trailmoments at the pole, and these are the cumulants at rational parameters (Proposition 5.13). Because the slopes sum to zero, the terms $x \log x$ of Stirling's formula cancel in every Gamma stack met, so the terms and the integrands on the shifted contours grow at most like $C^{|\mathbf{j}|}$, while $z^{e_\sigma(\mathbf{j})} \le z^{\varepsilon|\mathbf{j}|+e_\sigma(0)}$ for some $\varepsilon > 0$; below $z_0 = C^{-1/\varepsilon}$ every shifted contour contributes nothing in the limit and every sum converges absolutely. The expansion and P_c agree on $(0, z_0)$ and P_c is analytic on $(0, \infty)$, so the period is the continuation. At the regular singular point 0 the solutions have the Frobenius form, with exponents in finitely many classes $\rho + \mathbb{N}$, and the equation gives each coefficient sequence a recurrence, triangular in the power of $\log z$, with the indicial polynomial at $\rho + m$ as its leading coefficient. Under the summability hypothesis the expansion converges uniformly on a sector neighbourhood of $[z_0/2, 1]$, where $|z^e|$ and $|\log z|$ are bounded, so it is analytic there and equals P_c; at $z = 1$, $\log 1 = 0$.

(iii) The letter, or the deformed period, satisfies an equation with regular singular points only, ∞ among them: both are periods of families over $\mathbb{Q}(z)$, as in the proofs of (i) and (ii), and the Gauss–Manin connection of such a family is regular (Deligne's regularity theorem). L_ψ is analytic on the disc $|z| < 1$, where its series converges, and along every segment in the disc that ends at 1 it tends to $\sum_N \psi(N)$, which is finite (Abel's theorem, a chord ending at 1 lying in a Stolz angle); P_c is real analytic on $(0, \infty)$, so analytic in a neighbourhood of $(0, 1]$, around the points of S there as well, with the value $P_c(1)$ at 1. So Proposition 45.20 applies along γ with $b = 1$, with the derivatives at a read termwise: from the power series of L_ψ, and for P_c from the expansion of (ii), which converges absolutely at $a < z_0$ together with its termwise derivatives, a derivative of $z^e(\log z)^i$ being a combination of $z^{e-1}(\log z)^{i'}$, $i' \le i$. The period is $P_0 L_\psi(1)$ by (i) and $P_c(1)$ by (ii).

Let the monodromy be unipotent. The regular connections over $\mathbb{C}(z)$ with singular points in S and the local systems on $\mathbb{P}^1 \setminus S$ are equivalent categories, subquotients corresponding (the Riemann–Hilbert correspondence for regular connections), and a unipotent representation has the trivial representation of rank one as its only composition factor; so every factor N of L, of rank d, read over $\mathbb{C}(z)$, has a nonzero horizontal element. In a basis of N the horizontal elements over $\mathbb{C}(z)$ are the solutions in $\mathbb{C}(z)^d$ of a system with coefficients in $\mathbb{Q}(z)$, with poles only at its singular points, of bounded orders, and with bounded degrees, so they are the solutions of a linear system over $\mathbb{Q}$ and are spanned by those in $\mathbb{Q}(z)^d$; a horizontal element of N spans a submodule isomorphic to $\mathbb{Q}(z)$ with d/dz, which is N, N being simple. The same holds over $\overline{\mathbb{Q}}(z)$. Take, as in the proof of Proposition 45.20, a basis $e_1, \dots, e_h$ over $\mathcal{O} = \overline{\mathbb{Q}}[z][1/q]$ adapted to a composition series over $\overline{\mathbb{Q}}(z)$, so that A is upper triangular. The factor l has a horizontal element, the image of $r_l e_l$ with $r_l \in \overline{\mathbb{Q}}(z)$, whose zeros and poles lie in S, the diagonal entry being $-r_l'/r_l$; so r_l is a unit of $\mathcal{O}$, and replacing e_l by $r_l e_l$ makes the diagonal of A zero. Changing e_l by multiples over $\mathcal{O}$ of the e_m, $m < l$, in the order of $l - m$, changes A_{ml} by the derivatives of elements of $\mathcal{O}$ and otherwise only entries farther from the diagonal, and the classes of the $1/(z - s)$, s a finite point of S, span $\mathcal{O}/\partial\mathcal{O}$, the de Rham cohomology of the line less those points; so $A = \sum_s A_s/(z - s)$ with strictly upper triangular matrices A_s over $\overline{\mathbb{Q}}$. Then $Y = Y_0 G$ with $G = \sum_w \mathrm{I}(0; s_1, \dots, s_w; z)\, A_{s_1} \cdots A_{s_w}$, a finite sum, the iterated integrals taken along the segment from the tangential base point at 0, with $\log z$ real on $(0, 1)$; their expansions at 0 have the constant term 0 for $w \ge 1$, so Y_0 is the constant term at 0 of $Y = \left(\sum_i q_{il} y^{(i)}\right)_l$, $q_{il} \in \mathcal{O}$. For L_ψ, whose series has rational coefficients, Y_0

is algebraic; for P_c, by the expansion of (ii), it is a combination with algebraic coefficients of the $F_{\sigma,i}(\mathbf{j})$ with $e_\sigma(\mathbf{j})$ at most h plus the largest order of a pole of a q_{il} at 0, finitely many, the slopes of the e_σ being positive. At 1, $y = \sum_l p_l Y_l$ with $p_l \in \mathcal{O}$, whose Laurent coefficients at 1 are algebraic, and the expansion of $\mathrm{I}(0; s_1, \dots, s_w; z)$ at 1, in the powers of $1-z$ and of $\log(1-z)$, real on $(0,1)$, has as coefficients combinations with algebraic coefficients of the chains $\mathrm{I}(0; s_1, \dots, s_{w'}; 1)$, $w' \le w$, regularized at 1, by the composition of paths at the tangential base point at 1. So the constant term of y at 1, which is its limit (Proposition 45.20), is a combination of 1 and of these chains, with algebraic coefficients for L_ψ and with coefficients that are combinations of finitely many $F_{\sigma,i}(\mathbf{j})$ for P_c. When $S \subseteq \{0, \infty\} \cup \mu_M$ the chains are of level M, whose values lie in $\mathcal{C}^{(M)}$ (Proposition 45.5), and the period is $P_0 L_\psi(1)$. □

Corollary 45.22 (The values of a ray are read through chains over its tree). *As stated.*

Proof. (i) $\mathcal{D}_F[1] = \mathcal{D} \cdot 1$, and $\mathbb{C}(t) \otimes_{\mathbb{C}[t^{\pm 1}]} \mathcal{D}_F[1]$ is $\mathbb{C}(t)\langle\partial_t\rangle / \mathbb{C}(t)\langle\partial_t\rangle L_1$. A simple holonomic module on $\mathbb{C}^\times$ is supported at a point or is the intermediate extension of an irreducible local system on an open set; the generic fibre, which is exact, carries the first to 0 and the second to an irreducible module over $\mathbb{C}(t)$. So the factors of L_1 are the generic fibres of the composition factors of $\mathcal{D}_F[1]$ with a nonzero generic rank, and these are composition factors of $\mathcal{G}_F$, to which Theorem 39.56(iv) applies.

(ii) Let F_p be the filtration of $\boxtimes_c \mathbb{G}_c$ by the sums of the external products of terms of the children's filtrations whose indices add to p; the external product is exact in each factor, so gr_p is the sum of the external products of graded pieces whose indices add to p. Let $F_p\mathbb{G}_v$ be the image of $H^0(N_v)_+ F_p$ in $\mathbb{G}_v = H^0(N_v)_+\big(\boxtimes_c \mathbb{G}_c\big)$. The direct image has no cohomology in positive degrees (the proof of Theorem 39.56(ii)), so $H^0(N_v)_+ F_{p-1} \to H^0(N_v)_+ F_p \to H^0(N_v)_+ \mathrm{gr}_p \to 0$ is exact, and $F_p\mathbb{G}_v / F_{p-1}\mathbb{G}_v$, the image of $H^0(N_v)_+ F_p$ modulo that of $H^0(N_v)_+ F_{p-1}$, is a quotient of $H^0(N_v)_+ \mathrm{gr}_p$. At the root the same holds for $R_o|_{U_o}$, restriction to U_o being exact, and $H^0(R_o|_{U_o})_+\big((\boxtimes_c \mathbb{G}_c)|_{U_o}\big)$ is $\mathcal{G}_F$ (Theorem 39.56(ii)); the intersections with $\mathcal{D}_F[1]$ filter it, with graded pieces that are submodules of those of $\mathcal{G}_F$.

(iii) The fibre integrals are periods of $\mathcal{D}_F[1]$ (Definition 39.47), so they are annihilated by the annihilator of 1 and solve L_1, which has regular singular points only, ∞ among them (Deligne's regularity theorem for the Gauss–Manin connection, φ being regular on the smooth variety X_F, as in the proof of Proposition 39.54). So Proposition 45.20 applies. The values are the moments of the stride's law (Proposition 40.2(i)), $\langle 1 \rangle_k = \int_{(0, f^\star]} s^k \, \mu_f(ds)$, and the image of μ_f under the reciprocal has the density P_1, the orthant fibre integral of 1 being the density of the image of ω_0 on the orthant under $\varphi = f^{-1}$ (Definition 39.47); the change of variables $t = 1/s$ gives the moment.

(iv) The origin 0 and the direction $N(\mathbf{m}; \mathbf{s}, \mathbf{t})$ are integral, and $\kappa_{1,S}$ is N times the wall κ_S of $(\mathbf{m}; \mathbf{s}, \mathbf{t})$, the walls being linear in the data, so it is positive. With the origin 0, $\omega_0 = dy$ on the chart $\alpha_{e_0} = 1$, and the f of the ray (Theorem 38.14(ii)) is f_0^N, with $f_0 = \alpha^{\mathbf{m}} \prod_j K_j^{-s_j} \Psi_j^{-t_j}$ positive on the orthant and of degree 0 under the scale, the data being on the balance wall; so $P_F(\mathbf{m}; \mathbf{s}, \mathbf{t}) = \int_{y_{e_0}=0} f_0 \, dy = \int_{y_{e_0}=0} f^{1/N} dy$, which converges, the walls of the data being positive. The image of dy on the orthant under $\varphi = f^{-1}$ has the density P_1 on (A, ∞), as in (iii), and $f^{1/N} = \varphi^{-1/N}$; the change of variables $t = \varphi$ gives the moment, the integrand being positive. □

Corollary 45.23 (The letter of the closing along the tree). *As stated.*

Proof. (i) The proof of Theorem 39.56(ii) uses of the data only that the maps are morphisms of smooth affine varieties, the data of a mark a closed embedding, composing to the data of each vertex, and of the modules at the marks only that they are holonomic. Here $\tilde{\lambda}_e$ has the

coordinates α_e and α_e^{-1}, so it is a closed embedding; the node maps are polynomial, $\sigma_v = \sum_c \sigma_c$ and $\mu_v = \prod_c \mu_c$ composing to the sum and the product over B_v; and $\mathcal{O}_{\mathbb{C}^\times}\alpha_e^{m_e}$ is holonomic of rank one. So $\mathbb{L}_v = H^0(\tilde{\lambda}_v)_+\big(\boxtimes_{e\in B_v}\mathcal{O}\alpha_e^{m_e}\big)$. By Theorem 39.56(i), with this last coordinate, K_j and $\Psi_j = \alpha^{\mathcal{E}}K_j^{\Psi}(\alpha^{-1})$ are the readings at the root of the data of its children, and $\sigma_o \circ \prod_c \tilde{\lambda}_c = |\alpha|$. $P_0L_\psi(z)$ is the period at the data $(\mathbf{m};\mathbf{w})$ of the letters $Q_i = (1-z)M_i|\alpha|^{g_i} + zL_i$, homogeneous of the degrees g_i, so on the chart $\alpha_{e_0} = 1$ it is $\int \alpha^{\mathbf{m}}\prod_i Q_i^{-w_i}dy$, as the period is (Theorem 38.14(ii)), the form being of degree 0 on the balance wall. The module of $\alpha^{\mathbf{m}}\prod_i Q_i^{-w_i}$ on the torus and the z-line is $\big(\boxtimes_e \mathcal{O}\alpha_e^{m_e}\boxtimes\mathcal{O}\big)\otimes(\tilde{\lambda}\times\mathrm{id})^*\mathcal{K}$, $\tilde{\lambda} = \prod_c \tilde{\lambda}_c$, on the preimage of W. By the projection formula for $\mathcal{K}$, a connection on W, and the composition of direct images in degree 0, as in Theorem 39.56(ii), its direct image to the z-line is $H^0(\mathrm{pr}_z)_+\big(\mathcal{K}\otimes(\boxtimes_c\mathbb{L}_c\boxtimes\mathcal{O})|_W\big)$, and on the chart the scale contributes the factor $H^1_{\mathrm{dR}}(\mathbb{C}^\times)$ in the top degree. For $0 < z < 1$ the integrand vanishes on the boundary of the simplex and exact forms integrate to zero (the proof of Theorem 45.21(i)), so the integral over the orthant is a period.

(ii) The Taylor coefficients of L_ψ are rational, so the operators of bounded order and degree that annihilate it are the solutions of a linear system over $\mathbb{Q}$, and its annihilator over $\mathbb{C}(z)$ is generated by L. The period map from the submodule generated by the class of the integrand to the functions commutes with ∂_z, and its image is $\mathbb{C}(z)\langle\partial_z\rangle P_0L_\psi$, which is $\mathbb{C}(z)\langle\partial_z\rangle/\mathbb{C}(z)\langle\partial_z\rangle L$; so the factors of L, read over $\mathbb{C}(z)$, are subquotients of the generic fibre of the direct image of (i), and the generic fibre, which is exact, carries its composition factors to 0 or to the simple modules over $\mathbb{C}(z)$ (the proof of Corollary 45.22(i)). The rest is the proof of Theorem 39.56(iii), (iv) and of Corollary 45.22(ii) for these data: $H^0(\mathrm{pr}_z)_+$ and the $H^0(\tilde{N}_v)_+$ are right exact, $\mathcal{K}\otimes$, restriction to W and the external product are exact, the external product of simple holonomic modules is simple, $\mathcal{O}_{\mathbb{C}}$ on the z-line is simple, and $\mathbb{L}_e$ is the direct image of a simple module under a closed embedding. □

Definition 45.24 (The group of a module, of a function and of an input). As stated.

Proof. The field generated over $\mathbb{C}(y)$ by the solutions of N near x and their derivatives is a Picard–Vessiot extension for N, the field of constants $\mathbb{C}$ being algebraically closed, and its differential automorphisms over $\mathbb{C}(y)$, acting on $\mathrm{Sol}_x N$, form a linear algebraic group (Picard–Vessiot theory over $\mathbb{C}(y)$), whose unipotent radical is a normal subgroup. When the singular points are regular singular this group is the Zariski closure of the monodromy (Schlesinger's theorem). Continuing the solutions along a path from x to another point is an isomorphism of the two fields over $\mathbb{C}(y)$ that commutes with d/dy; it carries the group at x, its radical and their Lie algebras to those at the other point by a conjugation. □

Proposition 45.25 (The group counts the functions). *As stated.*

Proof. (i) The transcendence degree of a Picard–Vessiot extension of $\mathbb{C}(y)$ is the dimension of its group (Picard–Vessiot theory), and the field generated by the solutions near x and their derivatives is one (the proof of Definition 45.24).

(ii) The submodules of N correspond to the subspaces of $\mathrm{Sol}_x N$ that G_N keeps, a submodule to the solutions that vanish on it (the Galois correspondence of Picard–Vessiot theory). So for simple N, G_N acts irreducibly. The vectors fixed by the unipotent radical form a nonzero subspace (Kolchin's theorem), which G_N keeps, the radical being normal; so it is the whole space, and the radical, acting trivially and faithfully, is trivial.

(iii) The series gives a flag of $\mathrm{Sol}_x N$ that G_N keeps, whose graded pieces are the solutions of the S_j, irreducible by (ii). The kernel U of the action on the graded pieces is normal and unipotent, so it lies in the unipotent radical; the radical acts trivially on each irreducible graded piece, as in

(ii), so it lies in U. The solutions of $S_1 \oplus \cdots \oplus S_r$ and their derivatives generate a subfield that G_N keeps, and restriction to it maps G_N onto its group, which acts on the graded pieces; so G_N/U is the group of $S_1 \oplus \cdots \oplus S_r$. An element of the Lie algebra of U carries each step of the flag into the next one down, so a bracket of r of them vanishes.

(iv) With regular singular points Definition 45.19 applies, and by the induction in the proof of Proposition 45.20 the entries of the block j are sums of terms $c\,\mathrm{I}\,\beta$ with chains I of weight at most $j-1$.

(v) y^a is algebraic over $\mathbb{C}(y)$, of degree dividing the denominator of a, and multiplication by y^a carries the solutions of the module of W onto those of the module of y^aW. With F and F' the fields that the two sets of solutions generate with their derivatives, $E = F(y^a) = F'(y^a)$ is a Picard–Vessiot extension for the sum of the module of W and that of y^a, finite over F and over F'. Restriction maps the group of E onto those of F and of F' with finite kernels, so it maps the identity component of the first onto the identity components of the other two. The identity component fixes the algebraic closure of $\mathbb{C}(y)$ in E, so it fixes y^a, and on $y^a \operatorname{Sol}_x$ it acts as on Sol_x conjugated by y^a: under the identification the two identity components agree. □

Proposition 45.26 (Powers add nothing, distinct factors add). *As stated.*

Proof. (i) For such a construction Φ the solutions of $\Phi(N)$ lie in $\Phi(\operatorname{Sol}_x N)$, so the field they generate with their derivatives lies in that of N and is kept by G_N; restriction maps G_N onto the group of $\Phi(N)$ (the Galois correspondence of Picard–Vessiot theory), an element g acting by $\Phi(g)$, and this is a morphism of algebraic groups; a subquotient has as its group the image of the group of the module under restriction. A surjective morphism of algebraic groups is surjective on Lie algebras.

(ii) The field of $N_1 \oplus N_2$ is generated by those of N_1 and of N_2, so its group acts faithfully on $\operatorname{Sol}_x N_1 \oplus \operatorname{Sol}_x N_2$ inside $G_{N_1} \times G_{N_2}$, and it projects onto each factor by (i).

(iii) The group of $S_1 \oplus \cdots \oplus S_k$ is reductive: its unipotent radical acts trivially on each $\operatorname{Sol}_x S_j$, as in Proposition 45.25(ii). So its Lie algebra $\mathfrak{g}$ is reductive, and $\mathfrak{h} = [\mathfrak{g}, \mathfrak{g}]$ is semisimple, a sum of simple ideals, lying in $\bigoplus_j \mathfrak{s}_j$ and projecting onto each $\mathfrak{s}_j$ by (ii). A simple ideal of $\mathfrak{h}$ maps onto an ideal of $\mathfrak{s}_j$, so to 0 or isomorphically onto $\mathfrak{s}_j$; it cannot map onto two of them, which are not isomorphic, and each $\mathfrak{s}_j$ is reached. So each simple ideal of $\mathfrak{h}$ is one of the $\mathfrak{s}_j$ in its place, distinct ideals are distinct $\mathfrak{s}_j$, and $\mathfrak{h} = \bigoplus_j \mathfrak{s}_j$ (Goursat's lemma). □

Theorem 45.27 (A full Jordan block). *As stated.*

Proof. S has regular singular points, so G_S is the Zariski closure of its monodromy (Definition 45.24). Let u be the unipotent local monodromy with a single Jordan block and $\mathsf{N} = \log u$. The closure of the powers of u is a connected unipotent group, so u lies in the identity component G° of G_S and N in its Lie algebra. G° is reductive, as a normal subgroup of finite index of G_S, which is reductive by Proposition 45.25(ii); so the solutions are a sum of irreducible representations of G°, and u, with a single Jordan block, keeps no decomposition into two nonzero subspaces, so they are irreducible. The Lie algebra of G° is the sum of its centre, which acts by scalars, and the semisimple derived algebra $\mathfrak{s}$, and N, being nilpotent, lies in $\mathfrak{s}$. $\mathfrak{s}$ acts faithfully and irreducibly, so the solutions are a tensor product of faithful irreducible representations of its simple ideals; a nilpotent element acts on a tensor product of two spaces of dimension at least two with at least two Jordan blocks, since by the Jacobson–Morozov theorem each factor is a sum of irreducible representations of $\mathfrak{sl}_2$, the number of Jordan blocks is the number of irreducible summands of the product, and a product of two such sums of dimensions at least two has at least two, the product of two irreducible ones of dimensions $a, b \geq 2$ having $\min(a, b)$; so $\mathfrak{s}$ is simple. A simple Lie algebra

with a faithful irreducible representation in which a nilpotent element has a single Jordan block is $\mathfrak{sl}_2$ in Sym^{r-1}, $\mathfrak{sl}_r$, $\mathfrak{sp}_r$ for even r, $\mathfrak{so}_r$ for odd r, or $\mathfrak{g}_2$ for $r = 7$, in its standard representation (Gabber's theorem, in Katz's classification of the simple Lie algebras with a representation in which a nilpotent element has one Jordan block). The derived group of G° is the connected subgroup with the Lie algebra $\mathfrak{s}$, which gives (a), (b) and (c).

In case (a) let H be the image of SL_2. G_S normalizes H, and the normalizer of H in the general linear group of the solutions is H times the scalars: the automorphisms of SL_2 are inner, and the centralizer of the irreducible H is the scalars (Schur's lemma). So the monodromy ρ takes values in $H \cdot \mathbb{C}^\times$, whose quotient by the scalars is PGL_2. The fundamental group of the line less finitely many points is free, so the projective representation lifts to a representation ρ_2 in GL_2; $\mathrm{Sym}^{r-1}\rho_2$ and ρ agree up to scalars, so $\rho = \mathrm{Sym}^{r-1}\rho_2 \otimes \chi$ for a character χ, and ρ_2 is irreducible, ρ being so. By the correspondence between local systems on the line less finitely many points and modules with regular singular points, ρ_2 and χ are the monodromies of such modules S_2 and χ, and $S \cong \mathrm{Sym}^{r-1} S_2 \otimes \chi$, both having the monodromy ρ. In case (b) Sp_r is the stabilizer of an alternating form, SO_r the identity component of that of a symmetric form, and G_2 keeps the symmetric form of the SO_7 that contains it; for $r \geq 3$ the standard representation of SL_r is not isomorphic to its dual, so SL_r keeps no nonzero bilinear form. □

Theorem 45.28 (The class read by the tree and by its stride's law). *As stated.*

Proof. (i) By Section 42.6, $\Gamma(k)^2 P(k) = \int_0^\infty y^{k-1}\mathsf{g}(y)^s\,dy$, which is $(\mathsf{T}_{1-k;(1)}[x]\,\mathsf{g}^s\,\mathbb{I}_{(0,\infty)})((0,\infty))$, the kernel $\mathsf{Z}_{1-k;(1)}(y)$ being y^{k-1} (Definition 5.2). By Proposition 40.2(i), $P(k) = \int t^k\,\mu_s(dt) = (\mathsf{T}_{k;(1)}[x]\,\iota_*\mu_s)((0,\infty))$, and $\int t^k\,\mu_s(dt) = \int t^{k-1}\,t\,\mu_s(dt) = (\mathsf{T}_{1-k;(1)}[x]\,t\,\mu_s)((0,\infty))$. By Tonelli's theorem and Definition 2.1,

$$(\mathsf{T}_{1-k;(1)}[x]\,\mathsf{g}\,\mathbb{I}_{(0,\infty)})((0,\infty)) = \int_0^\infty x^{-1}e^{-x}\int_0^\infty y^{k-1}e^{-y/x}\,dy\,dx = \int_0^\infty x^{-1}e^{-x}\,\Gamma(k)\,x^k\,dx = \Gamma(k)^2.$$

For a nonnegative Borel function F on $(0,\infty)$ the substitution $y = xt$ at fixed t gives

$$\iint F(xt)\,\mathsf{g}(x)\,dx\;t\,\mu_s(dt) = \int_0^\infty F(y)\int \mathsf{g}(y/t)\,\mu_s(dt)\,dy = \int_0^\infty F(y)\,\mathsf{g}(y)^s\,dy$$

by Proposition 42.17(i); so $\big(\mathsf{g}\,\mathbb{I}_{(0,\infty)}\big)\boxtimes(t\,\mu_s) = \mathsf{g}^s\,\mathbb{I}_{(0,\infty)}$ (Definition 5.30), and Theorem 5.31(ii) at the index $1-k$ is the product $\Gamma(k)^2\cdot P(k)$ of the first display. The image of μ_s under ι is the image of the Lebesgue input of the chart under $\varphi = f^{-1}$, whose density on (A,∞) is P_1 (Definition 39.47; the proof of Corollary 45.22(iii)), with $A = K(\mathbf{1})^2 = s^2$ at the strength one (Theorem 38.15).

(ii) The ladder and the exchange relation of the Gramma give $\vartheta^2\mathsf{g} = y\,\mathsf{g}$ (Section 42.6), that is $y^2\mathsf{g}'' + y\,\mathsf{g}' - y\,\mathsf{g} = 0$. By Lemma 20.29(i) at $l = 0$,

$$\mathsf{g}(y) = \sum_{k\geq 0}\frac{y^k}{k!^2}\big(2(\log\Gamma)'(1+k) - \log y\big),$$

so continuing g once around 0 turns it into $\mathsf{g} - 2\pi i\,\mathsf{h}$ with $\mathsf{h}(y) = \sum_{k\geq 0} y^k/k!^2$, an entire function and, as a difference of two solutions, a solution. If $\mathsf{g}' = a\,\mathsf{g}$ with $a \in \overline{\mathbb{C}}(y)$, the continuation would satisfy the same equation, whose solutions near a point form a line, and $\mathsf{g} - 2\pi i\,\mathsf{h} = c\,\mathsf{g}$ for a constant c; $\mathsf{h}(0) = 1$ gives $c \neq 1$, and then $\mathsf{g} = 2\pi i\,\mathsf{h}/(1-c)$ would return to itself around 0. So g satisfies no equation of order one, its module M is $\mathbb{C}(y)\langle\partial_y\rangle/\mathbb{C}(y)\langle\partial_y\rangle(\vartheta^2 - y)$, of rank two, and its solutions near a point of $(0,\infty)$ are $\mathbb{C}\mathsf{g} + \mathbb{C}\mathsf{h}$.

The Wronskian w of two solutions satisfies $w' = -y^{-1}w$, so $w = c\,y^{-1} \in \mathbb{C}(y)$, and an element of G_M, fixing w, acts with determinant one: $G_M \subseteq \mathrm{SL}_2$. Continuation along a loop is an automorphism of the field of M over $\mathbb{C}(y)$ that commutes with d/dy, so the loop around 0 gives an element u of G_M, $u\mathsf{g} = \mathsf{g} - 2\pi i\,\mathsf{h}$ and $u\mathsf{h} = \mathsf{h}$, unipotent and not 1; the closure of its powers is a group $\mathbb{G}_a$ in the identity component G° of G_M. The connected subgroups of SL_2 that contain a unipotent element other than 1 are $\mathbb{G}_a$, the Borel subgroups and SL_2. If G° were one of the first two, it would keep exactly one line, the fixed line $\mathbb{C}\mathsf{h}$ of u, and G_M, which normalizes G°, would keep it: every element of G_M would multiply h by a constant, and h'/h, fixed by G_M, would lie in $\mathbb{C}(y)$ (the Galois correspondence of Picard–Vessiot theory). An entire function whose logarithmic derivative is rational has finitely many zeros, so it is Pe^Q with polynomials P and Q; h is not a polynomial, and

$$|\mathsf{h}(y)| \le \sum_{k\ge0} \frac{|y|^k}{k!^2} \le \Big(\sum_{k\ge0} \frac{|y|^{k/2}}{k!}\Big)^2 = e^{2\sqrt{|y|}}$$

leaves no room for $\deg Q \ge 1$, under which $|e^Q|$ grows like $e^{c|y|^{\deg Q}}$, $c > 0$, along a ray. So $G^\circ = \mathrm{SL}_2$, and $G_M = \mathrm{SL}_2$.

The solutions of the module of a function are spanned by its images under the group: an operator over $\mathbb{C}(y)$ that kills the function kills its images, and the monic operator whose solutions are their span has coefficients fixed by the group, hence in $\mathbb{C}(y)$. SL_2 moves g to every nonzero solution, so the solutions of the module of g^s are spanned by the s-th powers of all the solutions of M: they are the image of $\mathrm{Sym}^s(\mathbb{C}\mathsf{g}+\mathbb{C}\mathsf{h})$ under the multiplication of solutions. The multiplication is injective there, since a relation $\sum_j c_j \mathsf{g}^j\mathsf{h}^{s-j} = 0$ with some $c_j \ne 0$ would make g/h a root of a nonzero polynomial with constant coefficients, hence a constant, which it is not, h returning to itself around 0 and g not. So the module of g^s has rank $s+1$. The multiplication carries $\mathrm{Sym}^s M$ onto a module of rank at most $s+1$ that contains g^s, hence onto the module of g^s, and isomorphically, the ranks being equal. By Proposition 45.26(i) the group of g^s is the image of $G_M = \mathrm{SL}_2$ acting on Sym^s of its standard representation, where the kernel is $\{\pm1\}$ for even s and 1 for odd s; its dimension is three.

(iii) The module of P_1 over $\mathbb{C}(t)$ is generated by a nonzero period of the module that 1 generates along the centre ray of $\binom{[s]}{1}$, whose periods are exactly V_s and which is irreducible off its singular values (Proposition 42.29(ii)); so it is that module read over $\mathbb{C}(t)$, and its group is the group of V_s. The density of $t\,\mu_s$ on $(0, s^{-2})$ is $t\,\varrho_f(t) = t^{-1}P_1(t^{-1})$; the substitution $t \mapsto t^{-1}$ and the multiplication by a nonzero element of $\mathbb{C}(t)$ change neither the Picard–Vessiot field over $\mathbb{C}(t)$ nor its group, so $\iota_*\mu_s$ and $t\,\mu_s$ have the group of V_s.

Let $s \ge 5$ and $r = s - 1 \ge 4$. By Theorem 42.28(i) and (ii) that module is simple of rank r, and its monodromy at ∞ is unipotent with a single Jordan block; its singular points are regular singular, as are those of the module of 1 along every such ray (the proof of Corollary 45.22(iii)); so Theorem 45.27 applies; by Theorem 42.28(iii) the monodromy T around a sign value has $\mathrm{rank}(T-1) = 1$. In case (a) of Theorem 45.27, $T = c\,\mathrm{Sym}^{r-1}(h)$ with c the monodromy of χ and h that of S_2 around the same loop. If h is a scalar, T is a scalar and $\mathrm{rank}(T-\mu) \in \{0, r\}$ for every μ. If h is diagonalizable with eigenvalues $\lambda_1 \ne \lambda_2$, T is diagonalizable with the eigenvalues $c\lambda_1^{r-1-j}\lambda_2^j$, $0 \le j \le r-1$, and $\mathrm{rank}(T-\mu) = 1$ asks $r-1$ of them to equal μ; any $r-1$ of the r indices contain two consecutive ones, $r-1$ being at least 3, which gives $\lambda_1 = \lambda_2$. If h is not diagonalizable, $h = \lambda(1+\mathsf{n})$ with $\mathsf{n} \ne 0$ nilpotent, and $\mathrm{Sym}^{r-1}(1+\mathsf{n})$ is unipotent with a single Jordan block of size r, so $\mathrm{rank}(T-\mu) \ge r-1 \ge 3$. So case (a) is excluded. In case (b) with $r = 7$ the group normalizes the derived group G_2 of its identity component, and the normalizer of G_2 in GL_7 is G_2 times the scalars, its automorphisms being inner and its centralizer the scalars (Schur's lemma); so

$T = c\,h$ with $h \in G_2 \subset \mathrm{SO}_7$ and $\operatorname{rank}(h - c^{-1}) = 1$. Then c^{-1} is an eigenvalue of h of multiplicity at least six, and the eigenvalues of an element of SO_7, with their multiplicities, are closed under inversion, so $c^{-1} = \pm 1$. For $c^{-1} = 1$, h is unipotent with $\operatorname{rank}(h - 1) = 1$, a transvection, which no orthogonal group contains, the Jordan blocks of even size of an orthogonal unipotent element coming in pairs; for $c^{-1} = -1$, $\det h = 1$ makes the seventh eigenvalue 1, and h is an involution fixing a line, while every involution of G_2 fixes a space of dimension three. So the derived group is Sp_r for even r, that is for odd s, SO_r for odd r, or SL_r, of the dimensions $r(r+1)/2$, $r(r-1)/2$ and $r^2 - 1$, each at least $r(r-1)/2 = (s-1)(s-2)/2$. □

Corollary 45.29 (The word along the canonical tree). *As stated.*

Proof. (i) At a full lean one letter is active, so the hypothesis of Corollary 26.11 holds on every hinge tree; on the canonical hinge tree of a table whose weights factor across its bunches of width one, the series and parallel nodes contribute stacked Gammas times monomials in their weights (Proposition 26.9), and the period is the product of these, of the reciprocals of the Beta corners of the edges and of the periods of the prime nodes (Corollary 26.11). The dimension of the share side of a prime node is Corollary 26.8, and equal factors of a product give a power.

(ii) is Proposition 42.26(iii), where a cell of at least two marks enters through $\widehat{\mathsf{V}}_{\mathcal{A}}(k;\ell)$, the period of the family of its two hinge minors. The word of a parallel class of $s \geq 2$ marks is

$$\Gamma(\ell)^{-2} \int_0^\infty y^{\ell-1} \mathsf{G}_{0;(1,-1)}(1,y)^s \, dy = \Gamma(\ell)^{-2} \left(\mathsf{T}_{1-\ell;(1)}[x] \, \mathsf{G}_{0;(1,-1)}(1,x)^s \, \mathbb{I}_{(0,\infty)}\right)((0,\infty))$$

(Proposition 42.26(iii), Definition 5.2), and the group of its input is Theorem 45.28(ii). □

Corollary 45.30 (The far end of the pencil). *As stated.*

Proof. Let $P^{(1)}$ be the part of P_1 on which T_∞ has the eigenvalue 1; it lies in the solutions of W, which T_∞ keeps. By Proposition 39.54, $(T_\infty - 1)^{n-2} P^{(1)}$ is a nonzero multiple of the torus fibre integral T, which is not 0, its first coefficient being $\mathsf{C}_0(1) = 1$; so $P^{(1)}, (T_\infty - 1)P^{(1)}, \ldots, (T_\infty - 1)^{n-2} P^{(1)}$ are independent, and $r_P \geq n - 1$. If $r_P = n - 1$ they span the solutions of W, and T_∞ is unipotent there with a single Jordan block.

(i) The submodules of W correspond, reversing inclusion, to the subspaces of its solutions that the monodromy keeps (the proof of Proposition 45.25(ii)), and these are kept by T_∞. A unipotent map with a single Jordan block keeps only the kernels of the powers of itself less the identity, which form a chain, and on the quotient of two of them it has a single Jordan block.

(ii) A factor of rank $b \geq 2$ is simple, with regular singular points (the proof of Corollary 45.22(iii)) and the unipotent local monodromy T_∞ of a single Jordan block of size b, so Theorem 45.27 applies. The group of a module of rank one lies in $\mathrm{GL}_1 = \mathbb{G}_m$.

(iii) Proposition 45.25(iii), and Proposition 45.26(ii) applied to the sum of the factors one factor at a time. □

Proposition 45.31 (The group is computable). *As stated.*

Proof. Hrushovski's algorithm computes the differential Galois group of a linear differential equation with coefficients in $\overline{\mathbb{Q}}(y)$, whatever its singular points, as an algebraic group given by equations; its Lie algebra, its dimension and its unipotent radical follow by linear algebra. The relation of one mark is $y^2 u'' + y\,u' - y\,u = 0$. With algebraic weights the pencil φ, the variety X_F and the presentation of $\mathcal{G}_F$ in Definition 39.47 are defined over $\overline{\mathbb{Q}}$, and the module that 1 generates over $\mathbb{C}(t)$ is the one it generates over $\overline{\mathbb{Q}}(t)$ with the scalars extended; so the first relation among $1, \partial_t, \partial_t^2, \ldots$

over $\mathbb{C}(t)$ is a relation over $\overline{\mathbb{Q}}(t)$, and it is L_1. A solution of L_1 generates a quotient of the module of L_1, whose group is the image of that of L_1 (Proposition 45.26(i)). □

Definition 45.32 (The inputs and the group of a word). As stated.

Proof. The group of a sum of modules of finite rank over $\mathbb{C}(y)$ is defined by Definition 45.24; the modules here are those that the densities generate, of finite rank by the hypothesis. □

Lemma 45.33 (The transforms satisfy linear equations). *As stated.*

Proof. Let $\mathcal{B}_x$ be the table obtained by gluing $\mathcal{A}$ at its hinge to the one-mark cell of ratio $x > 0$ (Definition 23.10), at the masses k and the exponents (k, k), and $P(x)$ its period. Its weights are those of $\mathcal{A}$ times monomials in $x^{1/2}$, positive for $x > 0$, and its walls, which do not see the weights, are positive, the table being the connected table $\mathcal{A}$ with its hinge read as a mark (the proof of Proposition 42.26(i)). So P converges on $(0, \infty)$, and the argument of the proof of Theorem 45.21(ii), the letters now carrying these weights, gives a nonzero linear differential equation for P over $\mathbb{C}(x^{1/2})$, and so over $\mathbb{C}(x)$, the derivatives being integrals of insertions whose classes modulo exact forms lie in a twisted de Rham cohomology of finite dimension. By Theorem 23.9(ii) and Definition 23.19(1), $P(x) = \Gamma(k)^{-2} x^{-k} \int_0^\infty y^{k-1} \check{f}_{\mathcal{A}}(y)\, \mathsf{G}_{0;(1,-1)}(1, y/x)\, dy$, and by Tonelli's theorem, for $0 < \operatorname{Re} w < k$,

$$\int_0^\infty x^{w-1} P(x)\, dx = \frac{\Gamma(k-w)^2}{\Gamma(k)^2} \int_0^\infty y^{w-1} \check{f}_{\mathcal{A}}(y)\, dy = \frac{\Gamma(k-w)^2 \Gamma(w)^2}{\Gamma(k)^2}\, \widehat{\mathsf{V}}_{\mathcal{A}}(k; w),$$

the last by Proposition 42.26(iv). The equation of P has regular singular points only (the proof of Theorem 45.21(iii)), so P has expansions in powers and logarithms at 0 and at ∞, and its Mellin transform continues meromorphically to the plane, as the Mellin transform $\mathcal{M}$ regularized by those expansions, which is linear and has $\mathcal{M}[x^i (x\partial_x)^j F](w) = (-w - i)^j\, \mathcal{M}[F](w + i)$. This is the correspondence of Proposition 39.48 read with the kernel x^{w-1}. It carries the equation of P to a nonzero linear recurrence in w with polynomial coefficients for $\mathcal{M}[P]$, an identity of meromorphic functions. The dual transform has its lattice expansion at 0 (Proposition 23.8(v)) and is the Laplace transform of its hinge measure (Proposition 23.8(ii)), so $|y^m \check{f}_{\mathcal{A}}^{(m)}(y)| \le C_m \check{f}_{\mathcal{A}}(y/2)$ with $C_m = \sup_{u>0} u^m e^{-u/2}$; it is decreasing and $\int_1^\infty y^{w-1} \check{f}_{\mathcal{A}}(y)\, dy$ is finite for $0 < w < k$, so it is $o(y^{-w})$ at ∞ for every $w < k$. So each $y^i (y\partial_y)^j \check{f}_{\mathcal{A}}$ has a Mellin transform regularized at 0 by that expansion, meromorphic on $\operatorname{Re} w < k - i$, the rule above holds for these, and $\mathcal{M}[\check{f}_{\mathcal{A}}] = \Gamma(k)^2 \Gamma(k-w)^{-2} \mathcal{M}[P]$ on $\operatorname{Re} w < k$. The stacked Gamma $\Gamma(k)^2 \Gamma(k-w)^{-2}$ satisfies a recurrence of order one with polynomial coefficients, so $\sum_{i=0}^h c_i(w)\, \mathcal{M}[\check{f}_{\mathcal{A}}](w + i) = 0$ on $\operatorname{Re} w < k - h$ with polynomial coefficients not all zero, which is $\mathcal{M}[L \check{f}_{\mathcal{A}}] = 0$ there for $L = \sum_i c_i(-y\partial_y)\, y^i \neq 0$. A function with an expansion in powers and logarithms at 0 whose regularized Mellin transform vanishes on a half-plane has no term in that expansion, each term giving a pole, and then vanishes by the inversion of the Mellin transform; so $L \check{f}_{\mathcal{A}} = 0$. The transform $f_{\mathcal{A}}$ is the dual transform of the dual cell (Proposition 23.8(iv)), connected and plain, to which the same applies. □

Theorem 45.34 (What the word along the canonical tree reads). *As stated.*

Proof. (i) By Proposition 42.26(iii) and (v) to (vii) the value is the word described: the fibre of the root or its one integral, the fibre of every node read by (v) with the word of each of its cells set at its load, the one Trailmoment of (vi) at a node of S, and the integral of g^s for a class, by (iii) for a parallel class and (vi) for a series class. Below a node of S a cell other than a mark enters

through its dual transform under a parallel node and its transform under a series node, which by Proposition 42.26(iv) and the inversion of the Mellin transform is

$$\check f_{\mathcal A}(y)=\frac{1}{2\pi i}\int_{\operatorname{Re} z=z_0} y^{-z}\,\Gamma(z)^2\,\widehat{\mathrm V}_{\mathcal A}(k;z)\,dz,\qquad f_{\mathcal A}(y)=\frac{1}{2\pi i}\int_{\operatorname{Re} z=z_0} y^{-z}\,\Gamma(z)^2\,\widehat{\mathrm V}_{\mathcal A}(k;k-z)\,dz,$$

$0<z_0<k$, a fibre integral of dimension one of a stacked Gamma times the word of the cell, absolutely convergent because $\Gamma(z)^2$ decays exponentially along the line and $|\widehat{\mathrm V}_{\mathcal A}(k;z)|\le\widehat{\mathrm V}_{\mathcal A}(k;\operatorname{Re} z)$. Its integrals over half-lines are the Trailmoments listed, and everything else in it is stacked Gammas, monomials in the weights and the norms, and fibre integrals.

(ii) $\mathsf g$ satisfies $\vartheta^2\mathsf g=y\,\mathsf g$ (Theorem 45.28(ii)), its dilations the dilated equations, and the transforms the equations of Lemma 45.33. The module of a product $\prod_c F_c^{m_c}$ of such functions lies in the image of $\bigotimes_c \mathrm{Sym}^{m_c}$ of their modules under the multiplication of functions, a module closed under ∂_y that contains the product; so it is a subquotient of a construction from the sum N of the modules of the distinct F_c, and so is the sum of the modules of all the inputs. By Proposition 45.26(i) the group of the word is a quotient of G_N. In the canonical hinge tree no two series nodes and no two parallel nodes are adjacent (Theorem 23.16), so a cell other than a mark directly below a series or parallel node is rooted at a prime node or at a node of the other kind. With S empty the inputs are the $\mathsf g^s$, whose modules are the Sym^s of the module of $\mathsf g$ (Theorem 45.28(ii)); the group of their sum is the image of the group SL_2 of $\mathsf g$ acting on the sum of the Sym^s (Proposition 45.26(i)), with the kernel $\{\pm1\}$ when every s is even and 1 otherwise, -1 acting on Sym^s by $(-1)^s$.

(iii) The work counts each distinct integral once by its dimension (Definition 33.2): the fibre of the root, of dimension $2(N_{\mathcal H}-1)-(n_{\mathcal H}-1)$ (Proposition 42.26(ii), the core being connected by Proposition 21.3(iv)); the fibre of every other node read by (v), of dimension $2(N_{\mathcal C}+N_{\mathcal D})-p-3=2N_v-n_v-2$, the bases of the node being those of $\mathcal C$ with h added and those of $\mathcal D$, and its marks $h,h_1,\dots,h_p$, which for a series or parallel node with p cells directly below it is $p-1$; for each size s of class the one integral $\int_0^\infty y^{z-1}\mathsf g(y)^s\,dy$ of the index z, which is also the Trailmoment of (vi) at a class in S; for every other node of S its Trailmoment; and for each transform that a node of S reads of a cell other than a mark, the dual transform under a parallel node and the transform under a series node (Proposition 42.26(vi)), its inverse Mellin transform of (i), the two of one cell being different integrals. Equal subtrees have equal words, and a word that recurs is counted once; with every series and parallel node in S the multiplicities enter only as the powers of transforms. A distinct subtree other than a mark then brings at most two integrals besides the fibre of its root when that is a prime node: its Trailmoment or the integral of its class and one transform if it is rooted at a series or parallel node, which lies directly below no node of its own kind (Theorem 23.16), and its two transforms if it is rooted at a prime node; this is the bound. □

50.45 Chapter 46: finite algebra for scale reads

The letters of this chapter have complex coefficients and no roots on $[0,\infty)$. Two facts carry the proofs. First, along $[0,\infty)$ a letter P_j has a continuous argument with limits at 0 and at ∞, so for $x\to\infty$, $P_j(x)^{-w_j}=C_jx^{-w_j\deg P_j}(1+O(x^{-1}))$ with $C_j\ne0$, and $|P_j^{-w_j}|$ is $|P_j|^{-\operatorname{Re} w_j}$ up to factors bounded above and below on $[0,\infty)$: a read converges absolutely exactly where it does for positive letters of the same degrees. Second, the reduction of 46.7 is algebraic in $\mathbb F'$ and does not use the values of the letters.

Definition 46.6 (Insertions and reads on one scale). As stated, for letters without roots on $[0,\infty)$.

Proof. $P_j(0) \neq 0$ and P_j does not vanish on $[0,\infty)$, so a continuous logarithm of P_j along $[0,\infty)$ starting at the principal logarithm of $P_j(0)$ exists and is unique, and it defines $P_j^{-w_j}$; on $(0,\infty)$ it is locally a holomorphic branch, so $\big(P_j^{-w_j}\big)' = -w_j P_j' P_j^{-w_j-1}$, and the product rule gives $\big(x^\kappa \prod_j P_j^{-w_j} g\big)' = x^{\kappa-1} \prod_j P_j^{-w_j}\, \eth g$. The squarefree decomposition and the gcd splitting are computed in $\mathbb{F}[x]$ by gcds and exact divisions, so the q_k lie in $\mathbb{F}[x]$, and they divide $P_1 \cdots P_N$, so none vanishes at 0 or on $[0,\infty)$. For $\xi_\ell \in \mathbb{C} \setminus (-\infty, 0]$, $x + \xi_\ell$ stays in $\mathbb{C} \setminus (-\infty, 0]$ for $x \geq 0$, so the continuous branch is the principal one, that of 15.1 and 46.1. □

Theorem 46.7 (Reduction by the scale exchange). *As stated, for letters without roots on* $[0,\infty)$.

Proof. Write $\mu_k = \sum_j m_{jk} w_j$, so that $\eth = x\frac{d}{dx} + \kappa - \sum_k \mu_k \frac{x q_k'}{q_k}$ and $\mathfrak{A} = \mathbb{F}'[x, x^{-1}, Q^{-1}]$. Every $R \in \mathfrak{A}$ is a Laurent polynomial in x plus principal parts at the q_k.

Three reductions. (a) If R has a pole of order $h+1 \geq 2$ at q_k with leading numerator s, $\deg s < \deg q_k$, then

$$\eth\big(r\, q_k^{-h}\big) = -(h + \mu_k)\, \frac{x q_k' r}{q_k^{h+1}} + O\big(q_k^{-h}\big),$$

plus simple poles at the other $q_{k'}$ and no polynomial part and no pole at 0, $r\, q_k^{-h}$ vanishing at ∞ and being regular at 0; $x q_k'$ is prime to q_k, q_k being squarefree and $q_k(0) \neq 0$, so the extended Euclidean algorithm gives r with $-(h+\mu_k) x q_k' r \equiv s \bmod q_k$, one division by $h + \mu_k$. (b) If R has a pole x^{-r}, $r \geq 1$, at 0, $\eth(x^{-r}) = (\kappa - r)x^{-r} - \sum_k \mu_k x^{1-r} q_k'/q_k$, whose other terms have poles of order below r at 0, simple poles at the q_k and no polynomial part. (c) If the polynomial part of R has degree $a \geq 0$, $\eth(x^a) = \big(\kappa + a - \sum_j w_j \deg P_j\big) x^a$ plus a polynomial of degree below a plus simple poles at the q_k, since $x q_k'/q_k = \deg q_k + O(x^{-1})$ and $\sum_k \mu_k \deg q_k = \sum_j w_j \deg P_j$. Subtracting $\eth$ of a multiple at each step lowers the order of the pole, resp. the degree, and leaves $\sum_{i<D} c_i x^i/Q$ once the poles at the q_k are simple and there is no pole at 0 and no polynomial part; each step divides by one of the three numbers of the hypothesis.

Uniqueness. Let $\sum_i c_i x^i/Q = \eth g$ with $g \in \mathfrak{A}$, $g \neq 0$. A pole of order $h \geq 1$ of g at q_k gives $\eth g$ a pole of order $h+1$ by (a), but the left side has simple poles; so g is a Laurent polynomial. A pole x^{-r} of g at 0 gives $\eth g$ the pole $(\kappa - r)x^{-r}$, but $Q(0) \neq 0$; so g is a polynomial, of degree $a \geq 0$, and by (c) $\eth g$ is of order x^a at ∞, while the left side is $O(x^{-1})$. So $g = 0$ and every $c_i = 0$: $\dim_{\mathbb{F}'} \mathfrak{A}/\eth\mathfrak{A} = D$.

Reads. Let the reads of R and of the x^i/Q converge absolutely, so that $\Phi = x^\kappa \prod_j P_j^{-w_j} g$ has the absolutely integrable derivative $x^{\kappa-1} \prod_j P_j^{-w_j}\big(R - \sum_i c_i x^i/Q\big)$ and limits at 0 and at ∞. With ν_0 the order of g at 0 and a its degree at ∞, $\Phi = c_0 x^{\kappa+\nu_0}(1 + o(1))$ at 0 and $\Phi = c_\infty x^{\kappa + a - \sum_j w_j \deg P_j}(1 + o(1))$ at ∞, with $c_0, c_\infty \neq 0$ by the first fact above; a limit exists only if the exponent has negative real part at ∞, positive at 0, or is 0. At 0: if $\nu_0 \leq -1$ the exponent $\kappa - |\nu_0|$ is not 0 by hypothesis, and if $\nu_0 \geq 0$ its real part is positive since the read of $1/Q$ converges, $\operatorname{Re}\kappa > 0$. At ∞: if $a \geq 0$ the exponent is not 0 by hypothesis, and if $a \leq -1$ its real part is negative since the read of x^{D-1}/Q converges, $\operatorname{Re}(\kappa - \sum_j w_j \deg P_j) < 1$. So both limits are 0, $\langle \eth g \rangle = 0$, and $\langle R \rangle = \sum_i c_i \langle x^i/Q \rangle$; at symbolic exponents the identity holds on the open set of absolute convergence and continues. For the linear letters, $Q = \prod_\ell (x + \xi_\ell)$ is squarefree, the x^i/Q, $i < |J|$, and the $(x+\xi_\ell)^{-1}$ span the same space by partial fractions, and the three numbers are $\kappa - r$, $\kappa + a - |\mathbf{w}|$ and $w_\ell + h$, nonzero in $\mathbb{K}$. □

Definition 46.8 (Deformation; masters). As stated, along every admissible direction.

Proof. Along the deformation the three numbers of 46.7 are $\kappa - r + \lambda_0\varepsilon$, $\big(\kappa + a - \sum_j w_j \deg P_j\big) + \varepsilon\big(\lambda_0 - \sum_j \lambda_j \deg P_j\big)$ and $(\mu_k + h) + \varepsilon \sum_j m_{jk}\lambda_j$, polynomials in ε with nonzero slopes, hence nonzero in $\mathbb{F}'(\lambda_0, \boldsymbol{\lambda})(\varepsilon)$. At large real ε the exponent of a read at 0 has real part growing like $\lambda_0\varepsilon$ and at ∞ falling like $(\sum_j \lambda_j \deg P_j - \lambda_0)\varepsilon$, the moduli of the powers being those of positive letters up to bounded factors; so finitely many reads converge absolutely together, the coefficients of the reductions have no pole there, and 46.7 gives the identities there, hence as meromorphic functions of ε, the reads continuing meromorphically by the expansions of the integrands at 0 and at ∞ (8.4). Q divides $P_1 \cdots P_N$. The conditions are strict inequalities and finitely many inequations, invariant under positive scaling, so the admissible directions form an open cone; $(\frac{1}{2}; \mathbf{1})$ is in it, since $\sum_j \deg P_j \geq 1 > \frac{1}{2}$ and $\sum_j m_{jk} \geq 1$ for every k, q_k dividing some P_j. □

Lemma 46.9 (Simple poles at a corner). *As stated, along every admissible direction and for letters without roots on* $[0, \infty)$.

Proof. The three reductions of the proof of 46.7 act on separate parts of an insertion: (a) on the poles of order at least two at one q_k, (b) on the pole at 0, (c) on the polynomial part, and each step feeds only the lower orders of its own part and the simple poles, which form the remainder $\sum_i c_i x^i/Q$. In (c) the step at the degree a divides by $\big(\kappa + a - \sum_j w_j \deg P_j\big) + \varepsilon\big(\lambda_0 - \sum_j \lambda_j \deg P_j\big)$, which vanishes at $\varepsilon = 0$ for at most one a; in (b) the step at r divides by $\kappa - r + \lambda_0\varepsilon$, vanishing at 0 for at most one r; in (a), for each k, the step at h divides by $\mu_k + h + \varepsilon \sum_j m_{jk}\lambda_j$, vanishing at 0 for at most one h. Along each chain every other division is by a number holomorphic and nonzero near $\varepsilon = 0$. So for R holomorphic in ε, whose principal parts are then holomorphic in ε, every coefficient is a sum of terms with at most one division vanishing at $\varepsilon = 0$: at most a simple pole.

For a master write $H_i = \int_0^1 + \int_1^\infty$. At 0 the integrand is $x^{\kappa + \lambda_0\varepsilon - 1}\phi_\varepsilon(x)$ with ϕ_ε analytic at 0 and holomorphic in ε, and 8.4 gives poles at $\kappa + \lambda_0\varepsilon + l = 0$, $l \in \mathbb{N}$, all simple and at distinct points, at most one of them at $\varepsilon = 0$. At ∞, by the first fact above, the integrand is $x^{e(\varepsilon)-1}$ times a power series in x^{-1} holomorphic in ε, $e(\varepsilon) = \kappa - \sum_j w_j \deg P_j + i - D + \varepsilon\big(\lambda_0 - \sum_j \lambda_j \deg P_j\big)$, and $x \mapsto 1/x$ gives simple poles at $e(\varepsilon) = l$, $l \in \mathbb{N}$, at most one at $\varepsilon = 0$. So H_i has at most a simple pole there. □

Theorem 46.10 (Finitely many numbers at every corner). *As stated, along every admissible direction and for letters without roots on* $[0, \infty)$.

Proof. Absolute convergence of $\langle R \rangle_{\kappa, \mathbf{w}; \mathbf{P}}$ is a strict inequality at 0 and one at ∞, so the deformed read converges absolutely for ε near 0 and is holomorphic there, with the value $\langle R \rangle_{\kappa, \mathbf{w}; \mathbf{P}}$ at 0. By 46.8 it equals $\sum_i c_i(\varepsilon) H_i(\varepsilon)$ as a meromorphic function, and by 46.9 each product has at most a double pole, with the constant term $c_{i,-1}h_{i,1} + c_{i,0}h_{i,0} + c_{i,1}h_{i,-1}$. The constant term of a function holomorphic at 0 is its value. The masters do not involve R. The derivative ∂_ε^b of $x^{\lambda_0\varepsilon} \prod_j P_j^{-\varepsilon\lambda_j}$ is $\big(\lambda_0 \log x - \sum_j \lambda_j \log P_j\big)^b$ times it, the logarithms continuous along $[0, \infty)$, so the read of $R\big(\lambda_0 \log x - \sum_j \lambda_j \log P_j\big)^b$ is $b!$ times the coefficient of ε^b of $\sum_i c_i H_i$, which uses $h_{i,-1}, \ldots, h_{i,b+1}$: $(b+3)D$ numbers. For the last sentence write $\ell_0 = \log x$ and $\ell_j = \log P_j$. The b-th powers of the linear forms $\lambda_0\ell_0 - \sum_j \lambda_j\ell_j$, for $(\lambda_0; \boldsymbol{\lambda})$ in a dense subset of a nonempty open set, span the forms of degree b in $(\ell_0, \ldots, \ell_N)$: a linear functional vanishing on them is a polynomial in $(\lambda_0; \boldsymbol{\lambda})$ vanishing on a dense subset of an open set, hence zero, and its coefficients are, up to multinomial factors, its values on the monomials. The rational admissible directions are such a set, and a linear system with rational coefficients that has a solution has a rational one; so $\ell_0^{k_0} \prod_j \ell_j^{k_j}$

is a rational combination of finitely many such powers, and its read, absolutely convergent with that of R, is the same combination of reads along these directions. □

Theorem 46.11 (Integer rays have certified recurrences). *As stated, for letters without roots on* $[0,\infty)$.

Proof. Over $\mathbb{F}'(n,\varepsilon)$ the three numbers of 46.7 at the data $\big(\kappa+an+\frac{\varepsilon}{2},\mathbf{w}+n\mathbf{b}+\varepsilon\mathbf{1}\big)$ have the nonzero slopes $\frac12$, $\frac12-\sum_j \deg P_j$ and $\sum_j m_{jk}$ in ε. Reduce the $D+1$ insertions $y_k=x^{ak}\prod_j P_j^{-b_jk}$: $y_k=\partial_n g_k+\sum_i c_{ki}x^i/Q$, where the denominators of g_k and of c_{ki} are products of the three numbers. The $(D+1)\times D$ matrix (c_{ki}) has a nonzero vector in its left kernel, found by elimination; clearing denominators gives polynomials $p_k(n,\varepsilon)$, and dividing by the largest power of ε that divides all of them makes the $p_k(n,0)$ not all zero. Then $g=\sum_k p_kg_k$, divided by that power of ε, has $\partial_n g=\sum_k p_ky_k$, and its denominators are products of the three numbers and a power of ε, none vanishing identically in ε at an integer n. Fix an integer n at which the $D+1$ displayed reads converge, absolutely since the reads of a ray are read where they converge absolutely; they converge absolutely for small ε too. For all but finitely many small $\varepsilon\neq0$, g is defined and the exponents of $x^{\kappa+an+\varepsilon/2}\prod_j P_j^{-w_j-nb_j-\varepsilon}g$ at 0 and at ∞, which move with ε, are not 0; the argument of 46.7 then gives $\langle\partial_n g\rangle=0$, so $\sum_k p_k(n,\varepsilon)\langle1\rangle_{\kappa+a(n+k)+\varepsilon/2,\,\mathbf{w}+(n+k)\mathbf{b}+\varepsilon\mathbf{1}}=0$. Letting $\varepsilon\to0$, the reads being continuous there, gives the recurrence at n. □

Theorem 46.12 (Coefficient jets on one scale). *As stated, for letters without roots on* $[0,\infty)$, *with the powers of the changed letters continued in* u.

Proof. P_{ja}/P_j is continuous on $[0,\infty]$, P_j having no roots on $[0,\infty)$ and $\deg P_{ja}\le\deg P_j$, so M_{ja} is finite. On the polydisc $z_j=\sum_a u_aP_{ja}/P_j$ has $|z_j|\le\sum_a|u_a|M_{ja}<1$, so $P_j(x;u)=P_j(x)(1+z_j)$ has no roots on $[0,\infty)$, and the power continued in u from $u=0$, the polydisc being convex, is $P_j(x)^{-w_j}(1+z_j)^{-w_j}$ with the principal branch of the second factor. Then

$$(1+z_j)^{-w_j}=\sum_{m\ge0}\frac{(-1)^m(w_j)_m}{m!}z_j^m,\qquad z_j^m=\sum_{|n_j|=m}\frac{m!}{\prod_a n_{ja}!}\prod_a\Big(u_a\frac{P_{ja}}{P_j}\Big)^{n_{ja}},$$

and the product over j is the displayed series inside the read. It is dominated by $\prod_j\sum_m\frac{|(w_j)_m|}{m!}\rho_j^m$, $\rho_j=\sum_a|u_a|M_{ja}<1$, finite by the ratio test, times the absolutely integrable integrand of $\langle1\rangle_{\kappa,\mathbf{w};\mathbf{P}}$; so the read of the sum is the sum of the reads, absolutely, uniformly on smaller polydiscs, and holomorphic in u. Each coefficient is the read of the rational insertion $\prod_{j,a}(P_{ja}/P_j)^{n_{ja}}$, bounded on $[0,\infty)$, absolutely convergent with $\langle1\rangle_{\kappa,\mathbf{w};\mathbf{P}}$, and 46.10 gives it. The continuation in u fixes the branch: the continuous branch of $P_j(x;u)^{-w_j}$ along $[0,\infty)$ from its principal value at 0 can differ from it by a factor $e^{2\pi i\ell w_j}$, $\ell\in\mathbb{Z}$. □

50.46 Chapter 47: the module of a family

Definition 47.1 (The data space, the lattice and the master form). As stated.

Proof. (i) $\kappa_{\mathcal{E}}(\mathbf{d})=m_{\mathcal{E}}-\sum_j(s_jr_j+t_jr_j^*)$ is a nonzero linear form, so $\mathbb{D}_F$ is a hyperplane. For U nonempty and proper take $e\in U$ and $e'\notin U$: the point $\mathbf{m}=\mathbf{e}_e-\mathbf{e}_{e'}$, $\mathbf{s}=\mathbf{t}=\mathbf{0}$ lies on $\mathbb{D}_F$ and has $\kappa_U=1$.

(ii) f_λ is homogeneous of degree $v_{\mathcal{E}}-\sum_j(a_jr_j+b_jr_j^*)=\kappa_{\mathcal{E}}(\lambda)=0$, and on X_F no α_e, K_j or Ψ_j vanishes, so f_λ and $f_{-\lambda}$ are regular functions on X_F, inverse to each other, with the coefficients of the letters.

(iii) For integral a_j, b_j the principal powers on the orthant multiply, so $f_\lambda\,\omega_{\mathbf{d}} = \omega_{\mathbf{d}+\lambda}$. $\partial_{y_e}\log\alpha^{\mathbf{m}} = m_e$, $\partial_{y_e}\log K_j = \sum_{T\ni e}\theta_{j,T}\alpha^{\mathbf{1}_T}/K_j = R_{j,e}$ and $\partial_{y_e}\log\Psi_j = R^*_{j,e}$ (38.2(i)), which gives $c_e(\mathbf{d}) = \partial_{y_e}\log(\omega_{\mathbf{d}}/dy)$ and, with the data of λ, $c_e(\lambda) = \partial_{y_e}\log f_\lambda$. Every basis has r_j marks and every complement r^*_j, so $\sum_e R_{j,e} = r_j$, $\sum_e R^*_{j,e} = r^*_j$ and $\sum_e c_e(\mathbf{d}) = \kappa_{\mathcal{E}}(\mathbf{d})$.

(iv) The chart $y_{e_0} = 0$ is the section $\{\alpha_{e_0} = 1\}$, on which $\alpha^{\mathbf{m}-\mathbf{1}}d\alpha$ restricts to $\alpha^{\mathbf{m}}dy$; by Theorem 8.7 the integral of $\omega_{\mathbf{d}}$ there is the period. The walls of an insertion are those of Proposition 38.5. □

Theorem 47.2 (The relations in all the data). *As stated.*

Proof. A point $\mathbf{d}$ of $\mathbb{D}_F$ is the origin of a ray, for instance with the direction 0 (Definition 38.1), whose origin form is $\omega_{\mathbf{d}}$ and whose value at the strength 0 is $\langle g\rangle_0 = \langle g\rangle(\mathbf{d})$.

(i) The condition of Proposition 38.5(i) at the strength 0 is $\operatorname{Re}\kappa_U(\mathbf{d}) + \kappa_U(g) > 0$ for every nonempty proper U, that is $\mathbf{d}\in\mathcal{T}_g$, and the defects of that ray at the strength 0 are $c_e(\mathbf{d})$. So $\langle g\rangle(\mathbf{d})$ and $\langle(c_e(\mathbf{d})+\partial_{y_e})g\rangle(\mathbf{d})$ converge absolutely and the second is 0. The integrals $\int f_\lambda g\,\omega_{\mathbf{d}}$ and $\int g\,\omega_{\mathbf{d}+\lambda}$ have one integrand, $f_\lambda\omega_{\mathbf{d}} = \omega_{\mathbf{d}+\lambda}$, and the second converges absolutely for $\mathbf{d}+\lambda\in\mathcal{T}_g$.

(ii) By Lemma S19 at the origin $\mathbf{d}$, on the sector of an order π with the tails U_l, $g = \prod_l q_l^{\kappa_{U_l}(g)} g_\pi(q)$ and $\omega_{\mathbf{d}}/dy = \prod_l q_l^{\kappa_{U_l}(\mathbf{d})}\omega_{\pi,\mathbf{d}}(q)$ with $\omega_{\pi,\mathbf{d}} = \prod_j k_{j,\pi}^{-s_j}\psi_{j,\pi}^{-t_j}$, the factors $k_{j,\pi}, \psi_{j,\pi}$ smooth and positive on a neighbourhood of $[0,1]^{n-1}$ (Theorem 8.5(ii)); so, for $\mathbf{d}\in\mathcal{T}_g$,

$$\langle g\rangle(\mathbf{d}) = \sum_\pi \int_{[0,1]^{n-1}} \prod_l q_l^{x_l(\mathbf{d})-1} h_\pi(q,\mathbf{d})\,dq, \qquad x_l(\mathbf{d}) = \kappa_{U_l}(\mathbf{d}) + \kappa_{U_l}(g), \quad h_\pi = g_\pi\,\omega_{\pi,\mathbf{d}}.$$

h_π is smooth in q near the cube, with q-derivatives continuous in $(q,\mathbf{d})$ and entire in $\mathbf{d}$, the masses entering only through the exponents x_l. By Lemma 8.4 with the data $\mathbf{d}$ as its parameter, each term extends meromorphically in $(x,\mathbf{d})$, and on $\{\operatorname{Re}x_l > -M\ \forall l\}$ it is a finite sum of products of factors $(x_l+i)^{-1}$, $0\le i<M$, at most one for each l, with functions holomorphic there. The $x_l(\mathbf{d})$ are affine in $\mathbf{d}$ and not constant (Definition 47.1(i)), so the composite is meromorphic on $\{\mathbf{d} : \operatorname{Re}x_l(\mathbf{d}) > -M\ \forall l\}$ with poles only where some $x_l(\mathbf{d})$ is a nonpositive integer; M being arbitrary and every nonempty proper U a tail of some order, this continues $\langle g\rangle$ to $\mathbb{D}_F$ with poles on the stated hyperplanes. On $\mathcal{T}_g$ the integral converges absolutely and locally uniformly, so it is holomorphic there and agrees with the continuation. These insertions span $\mathbb{C}[X_F]$ (Definition 39.15(i)); the value of an element of $\mathbb{C}[X_F]$ is the sum of the continued values of the insertions in any writing of it as their combination, which does not depend on the writing, two writings having one integral on the open set where all their integrals converge, which contains $\eta\,\mathbf{d}_\circ$ for large $\eta>0$ (the gloss after Definition 47.1). So the evaluation $\mathbb{C}[X_F]\to\{\text{meromorphic functions on }\mathbb{D}_F\}$ is $\mathbb{C}$-linear, and it extends to $\mathbb{C}[X_F]\otimes\mathbb{K}_F$. An element $\sum_i \rho_i\,(c_{e_i}(\mathbf{d})+\partial_{y_{e_i}})g_i$ of the span, with insertions g_i of the above kind, has the value $\sum_i\rho_i(\mathbf{d})\cdot 0 = 0$ at every point of $\bigcap_i\mathcal{T}_{g_i}$ off the poles of the ρ_i, by (i); that intersection contains $\eta\,\mathbf{d}_\circ$ for large $\eta>0$, $\kappa_U(\eta\,\mathbf{d}_\circ) = \eta\sum_j c_j(U)$ (the gloss after Definition 47.1), and is open, so the value vanishes identically. For $g\in\mathbb{C}[X_F]$, $\langle f_\lambda g\rangle$ and $\langle g\rangle(\cdot+\lambda)$ are one integral on the open set of the $\mathbf{d}$ at which $\mathbf{d}+\lambda$ lies in the tubes of the insertions of a writing of g, which contains $\eta\,\mathbf{d}_\circ$ for large η; so they agree identically.

(iii) At a real $\mathbf{d}$ the form $\omega_{\mathbf{d}}/dy = \alpha^{\mathbf{m}}\prod_j K_j^{-s_j}\Psi_j^{-t_j}$ is positive on the orthant. □

Definition 47.3 (The module of a family; shifts; masters; shift matrices). As stated; that the shifts are well defined and the value depends only on the class is Theorem 47.4(i).

Theorem 47.4 (The module of a family). *As stated.*

Proof. (i) On $\mathbb{C}[X_F]\otimes\mathbb{K}_F$ put $\widetilde{\mathrm{Sh}_\lambda}(g\otimes r)=f_\lambda g\otimes\sigma_\lambda r$, well defined since it is $\mathbb{C}$-bilinear in (g,r), and σ_λ-semilinear. By Definition 47.1(iii), $\partial_{y_e}(f_\lambda g)=f_\lambda\big(c_e(\lambda)+\partial_{y_e}\big)g$, and c_e is linear in the data, so $\big(c_e(\mathbf{d})+\partial_{y_e}\big)(f_\lambda g)=f_\lambda\big(c_e(\mathbf{d}+\lambda)+\partial_{y_e}\big)g$. Written out, $(c_e(\mathbf{d})+\partial_{y_e})g=g\otimes m_e-\sum_j R_{j,e}g\otimes s_j-\sum_j R^*_{j,e}g\otimes t_j+\partial_{y_e}g\otimes 1$, and its image under $\widetilde{\mathrm{Sh}_\lambda}$ is $f_\lambda g\otimes(m_e+v_e)-\sum_j u_\lambda R_{j,e}g\otimes(s_j+a_j)-\sum_j u_\lambda R^*_{j,e}g\otimes(t_j+b_j)+f_\lambda\partial_{y_e}g\otimes 1=f_\lambda\big(c_e(\mathbf{d}+\lambda)+\partial_{y_e}\big)g$, which is $(c_e(\mathbf{d})+\partial_{y_e})(f_\lambda g)$, an element of $\mathcal{L}_F$. With the semilinearity, $\widetilde{\mathrm{Sh}_\lambda}\mathcal{L}_F\subseteq\mathcal{L}_F$, and Sh_λ is well defined on $\mathfrak{M}_F$ and σ_λ-semilinear. $f_\lambda f_\mu=f_{\lambda+\mu}$ and $\sigma_\lambda\sigma_\mu=\sigma_{\lambda+\mu}$ give $\mathrm{Sh}_\lambda\mathrm{Sh}_\mu=\mathrm{Sh}_{\lambda+\mu}$, and $\mathrm{Sh}_0=1$, so $\mathrm{Sh}_{-\lambda}$ is the inverse of Sh_λ. The value vanishes on $\mathcal{L}_F$ (Theorem 47.2(ii)), so it is a function of the class; for $m=[\sum_i g_i\otimes r_i]$, $\langle\mathrm{Sh}_\lambda m\rangle(\mathbf{d})=\sum_i r_i(\mathbf{d}+\lambda)\langle f_\lambda g_i\rangle(\mathbf{d})=\sum_i r_i(\mathbf{d}+\lambda)\langle g_i\rangle(\mathbf{d}+\lambda)=\langle m\rangle(\mathbf{d}+\lambda)$ (Theorem 47.2(ii)). So $\mathrm{Ann}\langle\cdot\rangle$, a $\mathbb{K}_F$-subspace, has $\mathrm{Sh}_\lambda\mathrm{Ann}\langle\cdot\rangle\subseteq\mathrm{Ann}\langle\cdot\rangle$ for every λ, with equality since $\mathrm{Sh}_{-\lambda}$ does the same; and $\langle 1\rangle=P_F$ is positive at the real points of $\mathcal{T}_1$ (Theorem 47.2(iii)), so $[1]\notin\mathrm{Ann}\langle\cdot\rangle$.

(ii) For $\lambda=(v;\mathbf{a},\mathbf{b})$, $\alpha^v\prod_j K_j^{-a_j}\Psi_j^{-b_j}=f_\lambda$, and $[f_\lambda\otimes 1]=\mathrm{Sh}_\lambda[1\otimes 1]$; these insertions, $\mathbf{a},\mathbf{b}\in\mathbb{N}^N$, span $\mathbb{C}[X_F]$ (Definition 39.15(i)). So $\mathfrak{M}_F$ is spanned by the $\mathrm{Sh}_\lambda[1]$, a submodule containing $[1]$ contains them all, and the values are those stated by Theorem 47.2(ii). The lattice vectors $\lambda^{\mathrm{m}}_e=(\mathbf{e}_e-\mathbf{e}_{e_0};\mathbf{0},\mathbf{0})$, $e\neq e_0$, $\lambda^K_j=(\mathbf{1}_{T_j};\mathbf{e}_j,\mathbf{0})$ and $\lambda^\Psi_j=(\mathbf{1}_{\mathcal{E}\setminus T'_j};\mathbf{0},\mathbf{e}_j)$, for bases T_j,T'_j of table j, generate $\mathbb{D}_F(\mathbb{Z})$: $(v;\mathbf{a},\mathbf{b})-\sum_j a_j\lambda^K_j-\sum_j b_j\lambda^\Psi_j=(w;\mathbf{0},\mathbf{0})$ with $w_{\mathcal{E}}=0$, which is $\sum_{e\neq e_0}w_e\lambda^{\mathrm{m}}_e$. For each of them $f_{-\mu}$ is a Laurent polynomial of degree 0: $\alpha^{\mathbf{e}_{e_0}-\mathbf{e}_e}$, $\alpha^{-\mathbf{1}_{T_j}}K_j$ and $\alpha^{-\mathbf{1}_{\mathcal{E}\setminus T'_j}}\Psi_j$. So $\mathrm{Sh}_{-\mu}$ maps the span $\mathfrak{M}_{\mathrm{L}}$ of the classes of the Laurent insertions into itself, injectively and semilinearly; a semilinear injection maps a basis of the finite-dimensional $\mathfrak{M}_{\mathrm{L}}$ (by (iii)) to an independent set, so $\mathrm{Sh}_{-\mu}\mathfrak{M}_{\mathrm{L}}=\mathfrak{M}_{\mathrm{L}}$ and $\mathrm{Sh}_\mu\mathfrak{M}_{\mathrm{L}}=\mathfrak{M}_{\mathrm{L}}$. So $\mathfrak{M}_{\mathrm{L}}$ is stable under the generators and their inverses, a submodule containing $[1]$, and it is $\mathfrak{M}_F$.

(iii) On the chart, X_F is the smooth affine variety of the points of the torus $(\mathbb{C}^\times)^{\mathcal{E}\setminus\{e_0\}}$ at which $\prod_j K_j\Psi_j$ does not vanish, of dimension $n-1$, with the basis dy_e, $e\neq e_0$, of its 1-forms. The 1-form $c(\mathbf{d})=\sum_{e\neq e_0}c_e(\mathbf{d})\,dy_e$ over $\mathbb{K}_F$ is closed: $c_e(\mathbf{d})=m_e-\sum_j s_j\partial_{y_e}\log K_j-\sum_j t_j\partial_{y_e}\log\Psi_j$, so $\partial_{y_{e'}}c_e=\partial_{y_e}c_{e'}$. So $\nabla=d+c(\mathbf{d})\wedge$ is an integrable connection on the structure sheaf of X_F over $\mathbb{K}_F$. In its twisted de Rham complex the forms of top degree are $(\mathbb{C}[X_F]\otimes\mathbb{K}_F)\,dy$, and for the form $g\,dy_{\hat e}$ of degree $n-2$, the product of the $dy_{e'}$, $e'\neq e,e_0$, $\nabla(g\,dy_{\hat e})=\pm\big(c_e(\mathbf{d})+\partial_{y_e}\big)g\,dy$. The relation at e_0 is minus the sum of the others: $\sum_e(c_e(\mathbf{d})+\partial_{y_e})g=\kappa_{\mathcal{E}}(\mathbf{d})\,g+\sum_e\partial_{y_e}g=0$, by Definition 47.1(iii) and by Euler's identity for the function g of degree 0. So $\mathcal{L}_F$ is the image of ∇ in top degree, and $\mathfrak{M}_F$ is the top cohomology. The algebraic de Rham cohomology of an integrable connection on a smooth affine variety over a field of characteristic zero is finite-dimensional, the fact that Theorem 38.31(i) uses over $\mathbb{C}(k)$; so $\mathfrak{M}_F$ is finite-dimensional.

(iv) $\mathbb{C}[X_F]=\Bbbk[X_F]\otimes_\Bbbk\mathbb{C}$, so $\big(\Bbbk[X_F]\otimes_\Bbbk\Bbbk(\mathbb{D}_F)\big)\otimes_{\Bbbk(\mathbb{D}_F)}\mathbb{K}_F=\mathbb{C}[X_F]\otimes_{\mathbb{C}}\mathbb{K}_F$, and every element $(c_e(\mathbf{d})+\partial_{y_e})g$, $g\in\mathbb{C}[X_F]$, is a $\mathbb{C}$-combination of those with $g\in\Bbbk[X_F]$, so $\mathcal{L}_F$ is the $\mathbb{K}_F$-span of $\mathcal{L}_{F,\Bbbk}$. A cokernel commutes with the extension of scalars, so $\mathfrak{M}_{F,\Bbbk}\otimes_{\Bbbk(\mathbb{D}_F)}\mathbb{K}_F=\mathfrak{M}_F$, and a $\Bbbk(\mathbb{D}_F)$-basis of $\mathfrak{M}_{F,\Bbbk}$, classes of insertions with coefficients in $\Bbbk$, is a $\mathbb{K}_F$-basis of $\mathfrak{M}_F$. Conversely the map $\mathfrak{M}_{F,\Bbbk}\to\mathfrak{M}_F$ is injective, $\mathbb{K}_F$ being a field extension of $\Bbbk(\mathbb{D}_F)$, so the classes of masters of $\mathfrak{M}_F$ with coefficients in $\Bbbk$ are independent over $\Bbbk(\mathbb{D}_F)$, and, the two dimensions being equal, they are a $\Bbbk(\mathbb{D}_F)$-basis of $\mathfrak{M}_{F,\Bbbk}$. f_λ has its coefficients in $\Bbbk$ and σ_λ keeps $\Bbbk(\mathbb{D}_F)$, so the shifts keep $\mathfrak{M}_{F,\Bbbk}$ and their matrices on such masters have entries in $\Bbbk(\mathbb{D}_F)$.

(v) $\mathrm{Sh}_{\lambda+\mu}[\mathbf{b}]=\mathrm{Sh}_\lambda(\mathbf{A}_\mu)[\mathbf{b}])=\sigma_\lambda(\mathbf{A}_\mu)\,\mathrm{Sh}_\lambda[\mathbf{b}]=\sigma_\lambda(\mathbf{A}_\mu)\mathbf{A}_\lambda[\mathbf{b}]$, and the matrix of a $\mathbb{K}_F$-linear relation on a basis is unique; the second identity is the first with λ and μ exchanged, and induction along a path gives the product. By (i) and the $\mathbb{K}_F$-linearity of the value, $\langle b_i\rangle(\mathbf{d}+\lambda)=\langle\mathrm{Sh}_\lambda[b_i]\rangle(\mathbf{d})=\sum_l\mathbf{A}_{\lambda,il}(\mathbf{d})\langle b_l\rangle(\mathbf{d})$. For masters of $\mathfrak{M}_F$ the coordinates of $[g]$ on the basis are unique, and the value is $\mathbb{K}_F$-linear. □

Proposition 47.5 (A ray is a line of the data space). *As stated.*

Proof. By Definition 38.1 the stride of the ray is $\alpha^{\mathbf{m}_1}\prod_j K_j^{-s_{1j}}\Psi_j^{-t_{1j}} = f_{\mathbf{d}_1}$, its origin form is $\omega_{\mathbf{d}_0}$, and its defects are $c_e^{(i)} = c_e(\mathbf{d}_i)$, so $c_e^{(0)} + k\,c_e^{(1)} = c_e(\mathbf{d}_0 + k\mathbf{d}_1)$, c_e being linear. For $r \in \mathcal{O}_\ell$ the element $r\,(c_e(\mathbf{d}) + \partial_{y_e})g$ restricts to $r|_\ell(k)\,(c_e^{(0)} + k\,c_e^{(1)} + \partial_{y_e})g$, an element of the relation space of the ray (Definition 38.4). $\mathrm{Sh}_{\mathbf{d}_1}[g \otimes r] = [f_{\mathbf{d}_1} g \otimes \sigma_{\mathbf{d}_1} r]$ restricts to $[fg \otimes r|_\ell(k+1)] = \mathrm{Sh}[g \otimes r|_\ell]$ (Definition 39.1). $f^k\omega_{\mathbf{d}_0} = \omega_{\mathbf{d}_0 + k\mathbf{d}_1}$, so $\langle g\rangle_k = \langle g\rangle(\mathbf{d}_0 + k\mathbf{d}_1)$ wherever the integral converges; when moreover every $\kappa_U(\mathbf{d}_1)$ is positive, the ray's values continue meromorphically in k (Proposition 38.5(ii)), and for one molecule so do the values in all the data (Theorem 47.2(ii)), and the two continuations agree, agreeing for all large real k. The restriction of the coefficients gives the values of x. The restriction $\mathcal{O}_\ell \to \mathbb{C}(k)$ is onto, k being the restriction of the affine function $(\varphi(\mathbf{d}) - \varphi(\mathbf{d}_0))/\varphi(\mathbf{d}_1)$ for a linear form φ with $\varphi(\mathbf{d}_1) \neq 0$, which exists as $\mathbf{d}_1 \neq 0$, so the restriction of $\mathbb{C}[X_F] \otimes \mathcal{O}_\ell$ is all of $\mathbb{C}[X_F] \otimes \mathbb{C}(k)$, and the relation space of the ray is the $\mathbb{C}(k)$-span of the restrictions of the generators of $\mathcal{L}_F$. □

Definition 47.6 (Symbols, relations and boxes in all the data). As stated.

Proof. The coefficients $m_e + u_e$, $s_j + a_j$ and $t_j + b_j$ are coordinates of $\mathbb{D}_F$ plus constants, none of them constant on $\mathbb{D}_F$. The evaluation of $\mathrm{MR}_e(g)$ is $(c_e(\mathbf{d}) + \partial_{y_e})g$ by the computation in the proof of Proposition 38.5(i) with the data $\mathbf{d}$ in the place of $(\mathbf{m}_0 + k\mathbf{m}_1; \mathbf{s}_0 + k\mathbf{s}_1; \mathbf{t}_0 + k\mathbf{t}_1)$. The generators generate $\mathbb{D}_F(\mathbb{Z})$ and have $f_{-\mu}$ a Laurent polynomial with coefficients in $\Bbbk$ (proof of Theorem 47.4(ii)); there are finitely many of them and of the U, so $\mathfrak{c}$ is a finite nonnegative number. The reduction is that of Definition 39.20 with G trivial, its proof applying verbatim; the symbol 1 is free, for otherwise $1 \in \mathcal{R}_{\mathfrak{B}}$ would evaluate into $\mathcal{L}_{F,\Bbbk}$ (Proposition 47.7(iv)) and $[1] = 0$, against Theorem 47.4(i). The monomials of a target have wall degree at most $\mathfrak{s} + \mathfrak{c} \leq \mathfrak{t}$ and the level $(\mathbf{0}, \mathbf{0})$ (Proposition 47.7(ii)), and the coefficients of $f_{-\mu}$ lie in $\Bbbk$, so every target lies in $\mathcal{F}_{\mathfrak{B}}$. □

Proposition 47.7 (Wall degrees and the relations of a box). *As stated.*

Proof. (i) is Proposition 39.16(i) for the ray with the direction $\mathbf{d}_1$, the stride $f_{\mathbf{d}_1}$ and $\kappa_{1,U} = \kappa_U(\mathbf{d}_1)$; for the convergence, $\kappa_U(g) \geq -\deg_\kappa g\,\kappa_U(\mathbf{d}_1)$ gives $\mathrm{Re}\,\kappa_U(\mathbf{d}) + \kappa_U(g) > 0$, that is $\mathbf{d} \in \mathcal{T}_g$, and Theorem 47.2(i) applies.

(ii) $\kappa_U(\alpha^u) = u_U$, and the first statement is Proposition 39.16(ii). For a generator $\mu = (v; \mathbf{a}, \mathbf{b})$, $\mathbf{a}, \mathbf{b} \in \mathbb{N}^N$, a monomial of $f_{-\mu} = \alpha^{-v}\prod_j K_j^{a_j}\Psi_j^{b_j}$ is α^w with $w = -v + \sum_j \big(\sum_{i \leq a_j} \mathbf{1}_{T_{j,i}} + \sum_{i \leq b_j} \mathbf{1}_{\mathcal{E}\setminus T'_{j,i}}\big)$ for bases $T_{j,i}, T'_{j,i}$ of table j, and by Theorem 7.13 $w_U \geq -v_U + \sum_j \big(a_j d_j(U) + b_j d_j^*(U)\big) = -\kappa_U(\mu) \geq -\mathfrak{c}\,\kappa_U(\mathbf{d}_1)$. The walls of Laurent symbols add, so $\kappa_U(\alpha^{u+w}) \geq -(\deg_\kappa \alpha^u + \mathfrak{c})\,\kappa_U(\mathbf{d}_1)$.

(iii) is Proposition 39.16(iii) and (iv), whose proofs use only the walls and Theorem 7.13.

(iv) The terms of a letter identity of a symbol of the box lie at levels within the bounds and have wall degree at most that of the symbol, by (iii). A term of the mark relation of a stem is at the level $(\bar{\mathbf{a}} - \mathbf{1}, \bar{\mathbf{b}} - \mathbf{1})$, $(\bar{\mathbf{a}} - \mathbf{1} + \mathbf{e}_j, \bar{\mathbf{b}} - \mathbf{1})$ or $(\bar{\mathbf{a}} - \mathbf{1}, \bar{\mathbf{b}} - \mathbf{1} + \mathbf{e}_j)$, within the bounds, with wall degree at most that of the stem. The letter identities evaluate to 0 and the mark relation of a stem s to $(c_e(\mathbf{d}) + \partial_{y_e})s$, an element of $\mathcal{L}_{F,\Bbbk}$, whose value vanishes identically by Theorem 47.2(ii).

(v) is the proof of Proposition 39.18(ii), which uses only the letter identities and the independence of distinct Laurent monomials.

(vi) is the proof of Proposition 39.18(iii), with $\bar{a}_j^- = \bar{a}_j - 1$ and $\bar{b}_j^- = \bar{b}_j - 1$: every bound being at least 1, every term of $\mathrm{MR}_e(x)$ at a raised level lies within the bounds, and the combination

formed there evaluates to $(c_e(\mathbf{d}) + \partial_{y_e})$ of 0 and has its terms in the box, so it lies in the span of the letter identities by (v). □

Theorem 47.8 (The box in all the data). *As stated.*

Proof. (i) $f_{-\mu}b_i - \sum_l \mathbf{B}_{\mu,il}b_l$ lies in $\mathcal{R}_{\mathfrak{B}}$, so it evaluates into $\mathcal{L}_{F,\Bbbk}$ (Proposition 47.7(iv)), and $[f_{-\mu}b_i] = \sum_l \mathbf{B}_{\mu,il}[b_l]$; $[f_{-\mu}b_i] = \mathrm{Sh}_{-\mu}[b_i]$. Let $\mathfrak{N}$ be the span of the $[b_l]$. Then $\mathrm{Sh}_{-\mu}\mathfrak{N} \subseteq \mathfrak{N}$ for every generator μ; $\mathrm{Sh}_{-\mu}$ is injective and semilinear on the finite-dimensional $\mathfrak{N}$, so $\mathrm{Sh}_{-\mu}\mathfrak{N} = \mathfrak{N}$ and $\mathrm{Sh}_{\mu}\mathfrak{N} = \mathfrak{N}$. The generators generate $\mathbb{D}_F(\mathbb{Z})$, so $\mathfrak{N}$ is a submodule; it contains $[b_1] = [1]$, so it is $\mathfrak{M}_F$ (Theorem 47.4(ii)). When the classes are independent they are a basis, and the matrix of $\mathrm{Sh}_{-\mu}$ on it is unique.

(ii) As an element of $\mathcal{R}_{\mathfrak{B}}$, $f_{-\mu}b_i - \sum_l \mathbf{B}_{\mu,il}b_l$ is a combination of letter identities and of mark relations $\mathrm{MR}_e(s)$ of stems s with coefficients $\nu_{\mu,i,e,s} \in \Bbbk(\mathbb{D}_F)$; evaluated, the letter identities give 0 and $\mathrm{MR}_e(s)$ gives $(c_e(\mathbf{d}) + \partial_{y_e})s$. Put $G_{\mu,i,e} = \sum_s \nu_{\mu,i,e,s}\, s$.

(iii) $\langle \mathrm{Sh}_{-\mu}[b_i]\rangle(\mathbf{d}) = \langle b_i\rangle(\mathbf{d} - \mu)$ by Theorem 47.4(i), and by (i) and the $\mathbb{K}_F$-linearity of the value it is $\sum_l \mathbf{B}_{\mu,il}(\mathbf{d})\langle b_l\rangle(\mathbf{d})$. At a real $\mathbf{d}$ as stated the stems, the b_l and the monomials of the targets have wall degree at most $\mathfrak{t}$, so their values converge absolutely and $\mathbf{d} \in \mathcal{T}_s$ for every stem s (Proposition 47.7(i)); Theorem 47.2(i) gives the value 0 for every term $(c_e(\mathbf{d}) + \partial_{y_e})s$.

(iv) The walls of symbols are integers and those of $\mathbf{d}_1$ positive integers, so every wall degree lies in $\frac{1}{L}\mathbb{Z}$ for L the least common multiple of the $\kappa_U(\mathbf{d}_1)$, that of a Laurent symbol in $\frac{1}{L}\mathbb{N}$ (Proposition 47.7(ii)), and $\mathfrak{c} \in \frac{1}{L}\mathbb{N}$; this is the discrete set. Let $\mathfrak{N}_{\mathfrak{s}} \subseteq \mathfrak{M}_{F,\Bbbk}$ be the span of the classes of the Laurent symbols of wall degree at most $\mathfrak{s}$, finitely many (Proposition 47.7(iii)). The $\mathfrak{N}_{\mathfrak{s}}$ increase with $\mathfrak{s}$ in a space of finite dimension (Theorem 47.4(iii), (iv)), so they are constant from some $\mathfrak{s}_0$ on, and their union is the span of the classes of all the Laurent insertions with coefficients in $\Bbbk$, which is $\mathfrak{M}_{F,\Bbbk}$ by the argument of Theorem 47.4(ii) over $\Bbbk$. Each of the finitely many Laurent symbols $\bar{g}$ of wall degree at most $\mathfrak{s}_0 + \mathfrak{c}$ has its class in $\mathfrak{N}_{\mathfrak{s}_0}$:

$$\bar{g} - \sum_h \lambda_{\bar{g},h}\, h = \sum_{e,i} \nu_{\bar{g},e,i}\, \big(c_e(\mathbf{d}) + \partial_{y_e}\big) G_{\bar{g},i},$$

with h running over the Laurent symbols of wall degree at most $\mathfrak{s}_0$, $\lambda, \nu \in \Bbbk(\mathbb{D}_F)$, and finitely many symbols $G_{\bar{g},i}$, the evaluations of the symbols spanning $\Bbbk[X_F]$ over $\Bbbk$. Take $\mathfrak{t} \geq \mathfrak{s}_0 + \mathfrak{c}$ in $\frac{1}{L}\mathbb{N}$ at least the wall degree of every $G_{\bar{g},i}$, and the level bounds $\bar{a}_j = 1 + \max a_j$ and $\bar{b}_j = 1 + \max b_j$ over the levels $(\mathbf{a}, \mathbf{b})$ of the $G_{\bar{g},i}$. Then every $G_{\bar{g},i}$ lies at a level at most $(\bar{\mathbf{a}} - \mathbf{1}, \bar{\mathbf{b}} - \mathbf{1})$ and has wall degree at most $\mathfrak{t}$, so every $\mathrm{MR}_e(G_{\bar{g},i})$ lies in $\mathcal{R}_{\mathfrak{B}}$ (Proposition 47.7(vi)); the formal combination $\bar{g} - \sum \lambda_{\bar{g},h} h - \sum \nu_{\bar{g},e,i}\mathrm{MR}_e(G_{\bar{g},i})$ has its terms in the box (Proposition 47.7(iii)) and evaluates to 0, so it lies in $\mathcal{R}_{\mathfrak{B}}$ (Proposition 47.7(v)), and so does $\bar{g} - \sum \lambda_{\bar{g},h} h$. Take $\mathfrak{s} = \mathfrak{s}_0$. A target $f_{-\mu}b_i$ is a $\Bbbk$-combination of Laurent symbols of wall degree at most $\mathfrak{s}_0 + \mathfrak{c}$ (Proposition 47.7(ii)), so it is congruent modulo $\mathcal{R}_{\mathfrak{B}}$ to a combination of Laurent symbols of wall degree at most $\mathfrak{s}_0$, whose reduction, which is the reduction of the target, involves only free Laurent symbols of wall degree at most $\mathfrak{s}_0$, by the ranking (Definition 39.20(ii)): the spanning set. So the box is accepted at $\mathfrak{s}_0$. A search through all the quadruples reaches this one, and the acceptance is decided by finitely many operations in $\Bbbk(\mathbb{D}_F)$. □

Definition 47.9 (Closings in all the data). As stated.

Proof. For $s_j + a_j \leq 0$ and $t_j + b_j \leq 0$ the function $g\,\omega_{\mathbf{d}}/dy = \alpha^{u+\mathbf{m}} \prod_j K_j^{-s_j-a_j} \Psi_j^{-t_j-b_j}$ is a Laurent polynomial of degree 0. A monomial α^w, $w_{\mathcal{E}} = 0$, is the constant 1 on the chart $\alpha_{e_0} = 1$ exactly when $w_e = 0$ for every $e \neq e_0$, that is when $w = 0$; so the constant term is the coefficient of α^0, whatever e_0, and it is the torus integral by Cauchy's formula in each variable. □

Proposition 47.10 (The closings are a solution in all the data). *As stated.*

Proof. For integral data $\Phi = \omega_{\mathbf{d}}/dy$ is a rational function with $\partial_{y_e} \log \Phi = c_e(\mathbf{d})$, so $\big(c_e(\mathbf{d}) + \partial_{y_e}\big) g \cdot \Phi = \partial_{y_e}(g\Phi)$. When $g\Phi$ is a Laurent polynomial, $\partial_{y_e} = \alpha_e \partial_{\alpha_e}$ multiplies its monomial α^w by w_e and kills its constant term, for $e \neq e_0$ on the chart; for e_0, Euler's identity gives $\partial_{y_{e_0}} = -\sum_{e \neq e_0} \partial_{y_e}$ on functions of degree 0. So the closing of $(c_e(\mathbf{d}) + \partial_{y_e})g$ is 0. $f_\lambda g\, \omega_{\mathbf{d}} = g\, \omega_{\mathbf{d}+\lambda}$ gives the second identity. For the third let the marks of F form one molecule, let $x = \sum_i g_i \otimes r_i \in \mathcal{L}_F$ have every r_i regular at $\mathbf{d}$ and every $\mathsf{C}(g_i)(\mathbf{d})$ defined, and let $\mathbf{d}_1$ be a positive direction (the gloss after Definition 47.1). Then $f_{\mathbf{d}} g_i = g_i\, \omega_{\mathbf{d}}/dy$ is a Laurent polynomial, and $\langle g_i \rangle(\mathbf{d} + k\mathbf{d}_1) = \langle f_{\mathbf{d}} g_i \rangle(k\mathbf{d}_1)$ (Theorem 47.2(ii)) is the value of $f_{\mathbf{d}} g_i$ along the ray with the origin 0 and the direction $\mathbf{d}_1$, as meromorphic functions of k, every $\kappa_U(\mathbf{d}_1)$ being positive (Proposition 47.5). Proposition 39.35(ii) at $j = 0$ gives $\lim_{k \to 0} k^{n-1} \langle g_i \rangle(\mathbf{d} + k\mathbf{d}_1) = V_1\, \mathsf{C}(g_i)(\mathbf{d})$ with $V_1 > 0$. The value of x vanishes identically (Theorem 47.2(ii)), and on the line $\mathbf{d} + \mathbb{C}\mathbf{d}_1$, which meets every polar hyperplane of the values in isolated points, $\kappa_U(\mathbf{d}_1)$ being positive, $\sum_i r_i(\mathbf{d} + k\mathbf{d}_1) \langle g_i \rangle(\mathbf{d} + k\mathbf{d}_1) = 0$; multiplying by k^{n-1} and letting $k \to 0$, the r_i being regular at $\mathbf{d}$, gives $V_1\, \mathsf{C}(x)(\mathbf{d}) = 0$. On the ray, $f = f_{\mathbf{d}_1}$ and $\omega_0 = \omega_{\mathbf{d}_0}$ (Proposition 47.5), so $\mathsf{C}_j(g) = \mathrm{CT}(g\, f^{-j} \omega_0/dy) = \mathsf{C}(g)(\mathbf{d}_0 - j\mathbf{d}_1)$, and $V_{\mathsf{C}}(x|_\ell)(k) = \sum_i r_i|_\ell(k)\, \mathsf{C}_{-k}(g_i)$ (Theorem 39.33) is $\mathsf{C}(x)(\mathbf{d}_0 + k\mathbf{d}_1)$. □

Theorem 47.11 (The elements of value zero). *As stated.*

Proof. For a positive direction $\mathbf{d}_1$ as in (b), with $\ell = \mathbf{d}_0 + \mathbb{C}\mathbf{d}_1$, the ray with the origin $\mathbf{d}_0$ and the direction $\mathbf{d}_1$ has an integral origin, an integral direction in which every letter has a positive exponent, and $\kappa_{1,S} = \kappa_S(\mathbf{d}_1) > 0$ for every nonempty proper S: the hypotheses of Theorem 39.57. The restriction $x|_\ell$ (Proposition 47.5) has a class in the module of that ray, with the values $\langle m \rangle(\mathbf{d}_0 + k\mathbf{d}_1)$ for all large k and the closings $\mathsf{C}(x)(\mathbf{d}_0 + k\mathbf{d}_1)$ for all integers k below some bound (Proposition 47.10).

(a)⇒(b) is the restriction of the value. (b)⇔(c) is (i)⇔(ii) of Theorem 39.57 for this class, ray by ray.

(b)⇒(a). By Theorem 39.57, for every such $\mathbf{d}_1$ the continuation of the values along the ray vanishes identically, so $\langle m \rangle$ vanishes on ℓ off its poles. Let C_+ be the open cone of the real points of $\mathbb{D}_F$ with $s_j, t_j > 0$ for every j and $\kappa_U > 0$ for every nonempty proper U; it contains $\mathbf{d}_\circ$ (the gloss after Definition 47.1), and its lattice points are the positive directions. A coefficient P/Q of x, with polynomials P, $Q \neq 0$, has a pole along the whole line $\mathbf{d}_0 + \mathbb{C}\mathbf{d}_1$ only when $Q(\mathbf{d}_0 + k\mathbf{d}_1)$ vanishes identically in k; if $Q(\mathbf{d}_0) \neq 0$ this never happens, and otherwise the coefficient of the highest power of k is the top homogeneous part of Q at $\mathbf{d}_1$, a nonzero polynomial in $\mathbf{d}_1$. So the positive directions excluded in (b) lie on a proper algebraic subset of $\mathbb{D}_F$. The rational points of C_+ off a proper algebraic subset are dense in C_+, and each is a positive multiple of a lattice point, so the half-lines $\mathbf{d}_0 + \mathbb{R}_{>0}\mathbf{d}_1$ over the allowed $\mathbf{d}_1$ fill a dense subset of $\mathbf{d}_0 + C_+$. The real points of $\mathbf{d}_0 + C_+$ that lie in every $\mathcal{T}_{g_i}$, g_i the insertions of x, form an open set that contains $\mathbf{d}_0 + y\mathbf{d}_\circ$ for large y; off the real zeros of the denominators of the coefficients of x, a set without interior, it leaves a nonempty open set W. On W the value $\langle m \rangle$ is real-analytic and vanishes on a dense subset, so it vanishes on W; a function holomorphic on a connected open set of $\mathbb{D}_F$ that vanishes on a nonempty open set of its real points vanishes there identically, its Taylor coefficients at a real point being real derivatives. The complement of the polar set of $\langle m \rangle$ is connected, so $\langle m \rangle = 0$.

$\mathrm{Ann}\langle \cdot \rangle$ is a submodule (Theorem 47.4(i)), and the equivalence of (a) and (c) describes it. The closings are proved relations (Definition 44.1). Along each ray of (c) the argument of Theorem 44.16(ii), with the dependence taken over $\mathbb{C}(k)$, decides the vanishing of the values, which is that of the closings, by finitely many closings of the class of $x|_\ell$, the closings being a solution of the

shift (Theorem 39.33); when the weights, the insertions of x and its coefficients are rational, $x|_\ell$ is the class of a rational combination of insertions, $\mathbf{d}_0$ and $\mathbf{d}_1$ being integral, and Theorem 44.16(ii) applies as stated, with closings that are rational numbers. $\mathrm{Ann}\langle\cdot\rangle$ is 0 by Proposition 47.15(ii) at $\mathbb{E} = \mathbb{D}_F$, which meets $\mathcal{T}_1$, the proof of (ii) there not using this theorem; so (a)–(c) hold exactly when $m = 0$, and $\langle g\rangle = \langle g'\rangle$ exactly when $[g - g'] = 0$, that is when the reductions agree. □

Proposition 47.12 (Value zero by finitely many closings). *As stated.*

Proof. (i) The elements of $\mathcal{G}$ form a basis of $\mathbb{D}_F(\mathbb{Z})$ and its negatives: for $(\mathbf{m};\mathbf{s},\mathbf{t}) \in \mathbb{D}_F(\mathbb{Z})$, $(\mathbf{m};\mathbf{s},\mathbf{t}) - \sum_j s_j\lambda_j^K - \sum_j t_j\lambda_j^\Psi = (\mathbf{m}';\mathbf{0},\mathbf{0})$ with $m'_{\mathcal{E}} = 0$, which is $\sum_{e\neq e_0} m'_e\lambda_e^{\mathrm{m}}$. Let $V_0 = \mathbb{K}_F m$ and $V_{i+1} = V_i + \sum_{\mu\in\mathcal{G}} \mathrm{Sh}_\mu V_i$. Since $\mathrm{Sh}_\mu(r\,\mathrm{Sh}_\lambda m) = \sigma_\mu(r)\,\mathrm{Sh}_{\lambda+\mu} m$ (Theorem 47.4(i)), V_i is the $\mathbb{K}_F$-span of the $\mathrm{Sh}_\lambda m$ with λ a sum of at most i elements of $\mathcal{G}$, and $V_i \subseteq V_{i+1} \subseteq \mathfrak{N}$. If $V_i = V_{i+1}$, every Sh_μ, $\mu \in \mathcal{G}$, carries V_i into itself, and so does every Sh_λ, λ being a sum of elements of $\mathcal{G}$: V_i is a submodule that contains m, and $V_i = \mathfrak{N}$. Until then the dimensions increase strictly, so $V_{d-1} = \mathfrak{N}$. The reductions of these shifts on masters of $\mathfrak{M}$, which Proposition 47.13 gives for $\mathfrak{M}_F$ and Theorem 48.18(iv) for the quotients it presents, are read off the shift matrices (Theorem 47.4(v)), and a basis among them, with the matrices $\mathbf{B}_\mu$, by eliminations over $\mathbb{K}_F$. A quotient of $\mathfrak{M}_F$ by a submodule of elements of value zero carries the shifts and the values, which factor through it (Theorem 47.4(i)), so what follows holds in $\mathfrak{M}$.

(ii) A denominator Q of a coefficient of x or of an entry of a $\mathbf{B}_\mu$ and every translate $Q(\cdot + \nu)$ vanish identically on no line parallel to $\mathbf{d}_1$, the coefficient of the highest power of k in $Q(\mathbf{p} + \nu + k\mathbf{d}_1)$ being the top homogeneous part of Q at $\mathbf{d}_1$; and no polar hyperplane $\kappa_U(\mathbf{d}) + \kappa_U(g) \in \{0, -1, -2, \dots\}$ of the value of an insertion (Theorem 47.2(ii)) contains such a line, since $\kappa_U(\mathbf{d}_1) > 0$. So $\langle m\rangle$ is meromorphic on every line parallel to $\mathbf{d}_1$.

If $\langle m\rangle = 0$, the closings vanish along the d rays by Theorem 47.11, (a)⇒(c), at the integral origins $\mathbf{d}_0 + \lambda_k$, no coefficient of x having a pole along the whole line.

Conversely let the closings vanish along the d rays, and put $\ell = \mathbf{d}_0 + \mathbb{C}\mathbf{d}_1$. The ray with the origin $\mathbf{d}_0 + \lambda_k$ and the direction $\mathbf{d}_1$ satisfies the hypotheses of Theorem 39.57, and the class of x restricted to its line has these closings (Proposition 47.10); so the continuation of the values along it vanishes identically: $\langle \mathrm{Sh}_{\lambda_k} m\rangle = \sigma_{\lambda_k}\langle m\rangle$ vanishes on ℓ, for every k. Let $\lambda \in \mathbb{D}_F(\mathbb{Z})$ be a sum $\mu_1 + \cdots + \mu_p$ of elements of $\mathcal{G}$. Applying the shifts of the μ_i one at a time, $\mathrm{Sh}_\lambda m = \sum_k c_k^\lambda \mathrm{Sh}_{\lambda_k} m$, c^λ the first row of a product of translates $\sigma_\nu(\mathbf{B}_{\mu_i})$, whose entries are regular at all but finitely many points of ℓ. The values intertwine the shifts and are $\mathbb{K}_F$-linear (Theorem 47.4(i)), so $\sigma_\lambda\langle m\rangle = \sum_k c_k^\lambda \sigma_{\lambda_k}\langle m\rangle$ vanishes on ℓ off a finite set, and $\langle m\rangle$, meromorphic on the line $\ell + \lambda$, vanishes on it identically.

Let $\mathbf{d}'_1$ be any positive direction such that no coefficient of x has a pole along the whole line $\mathbf{d}_0 + \mathbb{C}\mathbf{d}'_1$. For every integer j the point $\mathbf{d}_0 + j\mathbf{d}'_1$ lies on the line $\ell + j\mathbf{d}'_1$, and for all large j it lies in the tube of every insertion of x and off the poles of its coefficients, where $\langle m\rangle$ is holomorphic; so $\langle m\rangle(\mathbf{d}_0 + j\mathbf{d}'_1) = 0$ for all large j. That is (b) of Theorem 47.11 at the origin $\mathbf{d}_0$, and $\langle m\rangle = 0$.

Along each of the d rays the vanishing is decided by finitely many closings, as in the proof of Theorem 47.11. The excluded directions are the zeros of finitely many nonzero homogeneous polynomials, a cone without interior points; the open cone C_+ of that proof has rational points off it, and an integral multiple of such a point is a positive direction off it. □

Proposition 47.13 (Masters from a box). *As stated.*

Proof. (i) If the classes of $\mathbf{b}$ are independent they are masters, and $\mathbf{B}_\mu = \mathbf{A}_{-\mu}$ is invertible (Theorem 47.8(i), Theorem 47.4(v)).

(ii) In $\mathfrak{M}_F$, $\mathrm{Sh}_{-\mu}[\mathbf{b}] = \mathbf{B}_\mu[\mathbf{b}]$ (Theorem 47.8(i)); applying Sh_μ, $[\mathbf{b}] = \sigma_\mu(\mathbf{B}_\mu)\,\mathrm{Sh}_\mu[\mathbf{b}]$, so $\mathrm{Sh}_\mu[\mathbf{b}] = \sigma_\mu(\mathbf{B}_\mu)^{-1}[\mathbf{b}]$. So the map $\pi : \varepsilon_i \mapsto [b_i]$ of $\Bbbk(\mathbb{D}_F)^{\mathbf{b}}$ onto $\mathfrak{M}_{F,\Bbbk}$, onto by Theorem 47.8(i) and Theorem 47.4(iv), carries $T_{\pm\mu}$ to $\mathrm{Sh}_{\pm\mu}$, and its kernel is carried into itself by the maps. The kernel contains the commutators and the $T_{-\mu}T_\mu\varepsilon_i - \varepsilon_i$, $T_\mu T_{-\mu}\varepsilon_i - \varepsilon_i$, the shifts commuting and $\mathrm{Sh}_{-\mu}\,\mathrm{Sh}_\mu = 1$; it contains the $\varepsilon_i - \rho(\lambda_i)$, since $\pi(\rho(\lambda)) = \mathrm{Sh}_\lambda[1]$ and $[b_i] = [f_{\lambda_i}] = \mathrm{Sh}_{\lambda_i}[1]$ (Theorem 47.4(ii)); and it contains the images of the letter identities and of the mark relations at [1], which are relations of $\mathfrak{M}_F$. So $\mathfrak{N} \subseteq \ker\pi$, and π induces a map $\bar\pi$ of the quotient onto $\mathfrak{M}_{F,\Bbbk}$.

Modulo $\mathfrak{N}$, $\rho(\lambda)$ does not depend on the path, the steps of two paths being reordered and cancelled by the commutators and the inverse pairs, and $\rho(\lambda+\nu) \equiv T_\nu\rho(\lambda)$ for ν a generator or the negative of one. $\mathfrak{M}_{F,\Bbbk}$ is the $\Bbbk(\mathbb{D}_F)$-span of the shifts of [1] modulo the shifts of the letter identities and of the mark relations (the proof of Theorem 48.18(ii)), and ρ carries the shift by λ of such a relation at [1] to the image of its image under the maps of a path to λ, which lies in $\mathfrak{N}$. So $\mathrm{Sh}_\lambda[1] \mapsto \rho(\lambda)$ is a well-defined map ι of $\mathfrak{M}_{F,\Bbbk}$ to the quotient, semilinear for the shifts. $\bar\pi\iota(\mathrm{Sh}_\lambda[1]) = \pi(\rho(\lambda)) = \mathrm{Sh}_\lambda[1]$, and $\iota\bar\pi(\varepsilon_i) = \rho(\lambda_i) \equiv \varepsilon_i$. So $\bar\pi$ is an isomorphism; the paths enter $\mathfrak{N}$ only through the classes of the $\rho(\lambda)$, which they do not change. A basis of the quotient among the ε_i goes to masters, and the matrices of the $T_{\pm\mu}$ on it are their shift matrices. The quotient is found by finitely many eliminations: the span of the listed vectors, closed under the finitely many maps, stabilizes, its dimension increasing until it does.

(iii) Fix $\mathfrak{s}$ at which some box is accepted (Theorem 47.8(iv)), and let $\mathbf{b}'$ be the free Laurent symbols of wall degree at most $\mathfrak{s}$ in it. The linear relations among the classes of the Laurent symbols of wall degree at most $\mathfrak{s}$, finitely many, form a subspace of finite dimension; each of a basis of it is an element of $\mathcal{L}_F$, a finite combination of the $(c_e(\mathbf{d}) + \partial_{y_e})g$ (Definition 47.3(i)), whose evaluations are the mark relations of finitely many symbols, together with finitely many letter identities (Definition 47.6(ii)). A box with $\mathfrak{t}$ and level bounds large enough contains these, and in it the free Laurent symbols of wall degree at most $\mathfrak{s}$ have independent classes. It is still accepted at $\mathfrak{s}$: the targets reduce to combinations of symbols of wall degree at most $\mathfrak{s}$ modulo the smaller relations, and every such symbol reduces modulo the larger ones to free symbols of wall degree at most its own, the ranking ordering the Laurent symbols by wall degree. Its matrices are then invertible by (i), and the search reaches it.

For a family of positive letters the same proof holds with Theorem 48.3(iii), (iv) in the place of Theorems 47.4 and 47.8. □

Proposition 47.14 (Value zero on a subspace of the data). *As stated.*

Proof. (i) On V_W, $\log f(e^y) = \langle \mathbf{m}_1, y\rangle - \sum_i w_{1,i} \log L_i(e^y)$, the sum over the letters of W_1. The Hessian of $\log L_i(e^y)$ in y is the covariance of the exponent $\mathbf{t}$ under the probability proportional to $c_{i,\mathbf{t}} e^{\langle \mathbf{t}, y\rangle}$ on the support of L_i; it is positive semidefinite, and its kernel is the set of the directions on which every difference of two exponents of L_i vanishes. The differences of two exponents of one letter of W_1 generate M_{W_1}, and $M_{W_1} = M_W$, W_1 having the active molecules of W (Theorem 48.23(i)), while $M_W \otimes \mathbb{R}$ is the dual of V_W. So $-\operatorname{Hess}\log f = \sum_i w_{1,i}\,\mathrm{Cov}_i$ is positive definite on V_W at every point, and $\log f$ is strictly concave. Every wall of $\mathbf{d}_1$ is positive, so on each cone of a fan $f = \prod_k q_k^{\kappa_{v_{\pi,k}}(\mathbf{d}_1)} \prod_i k_{i,\pi}(q)^{-w_{1,i}}$ with the $k_{i,\pi}$ bounded above and below on the cube (Lemma 48.2(iii)), and f tends to 0 as some q_k does: $\log f$ tends to $-\infty$ at infinity, attains its maximum, and has no other critical point, the maximum being nondegenerate.

For the converse, the derivative of $\log f$ along $v \in V_W$ at $y^\circ = \log\alpha^\circ$ is $\langle \mathbf{m}_1 - \sum_i w_{1,i} R_i(\alpha^\circ), v\rangle$, the occupations being the logarithmic derivatives of the letters; so with $\mathbf{m}_1 = \sum_i w_{1,i} R_i(\alpha^\circ)$ the point y° is critical, and by the first part it is the native gauge. $R_i(\alpha^\circ)$ is the mean of the exponents of L_i under a probability that charges every exponent of its support, so it lies in the relative interior

of the Newton polytope $\mathcal{N}_{L_i}$; so $\mathbf{m}_1 - \sum_i w_{1,i}\mathbf{t}_i = \sum_i w_{1,i}(R_i(\alpha^\circ) - \mathbf{t}_i)$ lies in the relative interior of $\sum_i w_{1,i}(\mathcal{N}_{L_i} - \mathbf{t}_i)$, the sums over W_1, a polytope of the dimension r_W in $\vec{\mathcal{N}}_W$. So the point lies in $\mathbb{D}_W$, and every wall of W_1 at it is positive (Theorem 48.3(i)). The walls of W at it are those of W_1: the letters with the exponent 0 add nothing to them, and W and W_1 have one fan, that of their active molecules (Theorem 48.23(i)). The occupations at a rational point are rational in it and in the weights, so for rational α° and weights the point is rational, and an integral multiple of it, which has the same native gauge, is integral. The walls are linear forms and the conditions on the exponents are linear, so the set of the real points with the stated exponents and every wall positive is an open cone in the real points of the subspace on which the exponents outside W_1 vanish; when $\mathbb{E}$ is defined over $\mathbb{Q}$ and meets it, the intersection is open in the real points of a subspace defined over $\mathbb{Q}$, its rational points are dense in it, and a positive integral multiple of a rational point of it is an integral point of it, a native direction of $\mathbb{E}$. On a chart of V_W the native gauge is a common zero of the defects $c_e(\mathbf{d}_1)$, rational functions of the point with coefficients in the field of the weights, and it is isolated, the Hessian being nonsingular there; an isolated point of the zeros of polynomials over a field has coordinates algebraic over that field.

(ii) Along the line, $\langle g_l\rangle(p+k\mathbf{d}_1) = \int_{V_W} g_l\,\omega_p\,f^k$, converging absolutely for $\operatorname{Re} k$ large, $\mathbf{d}_1$ having positive walls (Lemma 48.2(iii)). By (i), $y^\star$ is a nondegenerate maximum of the real function $\log f$ and the only critical point; outside a neighbourhood of it $f \le f^\star - \delta$ for some $\delta > 0$, so that part contributes $O\big((f^\star-\delta)^k\big)$, and near it the orthant is a steepest-descent disc. Laplace's method there, as in the proof of Theorem 38.6(i) with the origin form ω_p, gives

$$\langle g_l\rangle(p+k\mathbf{d}_1) \;\sim\; c_\star\,\frac{\omega_p}{dy}(\alpha^\star)\,g_l(\alpha^\star)\,(f^\star)^k k^{-r/2}\sum_{i\ge 0} P_{l,i}(p)\,k^{-i},$$

$P_{l,0} = 1$ and $P_{l,i}$ a finite combination of Gaussian moments of the covariance $(-H)^{-1}$, each times Taylor coefficients at $y^\star$ of $\log f$ and of $G = g_l\,\omega_p/dy$ divided by its value, of total order at most $2i$ in the latter. Now $\log G = \log g_l + \langle \mathbf{m}_p, y\rangle - \sum_i w_{p,i}\log L_i(e^y)$ is linear in p, so a Taylor coefficient of $G/G(y^\star)$ of order j is a polynomial in p of degree at most j, with coefficients formed from the Taylor coefficients of $\log g_l$ and of the $\log L_i$; and $P_{l,i}$ is a polynomial in p of degree at most $2i$. Off the p for which some r_l has a pole along the whole line, a proper algebraic subset, $r_l(p+k\mathbf{d}_1)$ is a rational function of k with its expansion at $k=\infty$, of degree at most ν, whose coefficients are rational functions of p; multiplying the expansions and collecting the powers of k gives the display, with

$$Q_i = \sum_l \sum_{a+i'=i} r_{l,a}(p)\,g_l(\alpha^\star)\,P_{l,i'}(p), \qquad r_l(p+k\mathbf{d}_1) = k^\nu \sum_a r_{l,a}(p)\,k^{-a}.$$

The Gaussian moments of $(-H)^{-1}$ and the Taylor coefficients of $\log f$, $\log g_l$ and $\log L_i$ at $y^\star$ are rational in $\alpha^\star$, the weights and the data of $\mathbf{d}_1$ and of g_l, which gives the field.

(iii) If $\langle x\rangle = 0$ on $\mathbb{E}$, then at every p off the subset of (ii) the left side of the display vanishes for all large real k, and the asymptotic expansion of 0 is 0: every $Q_i(p)$ vanishes, so every Q_i is 0. Conversely let every Q_i be 0, and fix p off that subset. The expansion of $\langle x\rangle(p+k\mathbf{d}_1)$ vanishes, and the proof of Theorem 39.57, (iii)⇒(ii), applies along the line with $n-1=r$: by (i) the level sets $\{f=t\}$, $0<t<f^\star$, are compact real-analytic hypersurfaces of V_W without critical points; by the coarea formula $\langle g_l\rangle(p+k\mathbf{d}_1) = \int_0^{f^\star} t^k\rho_l(t)\,dt$ for $\operatorname{Re} k$ large, ρ_l real-analytic on $(0,f^\star)$, complex-valued, and by the Morse lemma at $y^\star$ equal to $(f^\star-t)^{(r-2)/2}$ times a function analytic at $f^\star$; with a common denominator of the $r_l(p+k\mathbf{d}_1)$ and Watson's lemma, the vanishing of the expansion gives the vanishing of $\langle x\rangle(p+k\mathbf{d}_1)$ for $\operatorname{Re} k$ large, and so of its continuation in k. The lines $p+\mathbb{C}\mathbf{d}_1$, p off a proper algebraic subset of $\mathbb{E}$, fill a dense subset of $\mathbb{E}$, and $\langle x\rangle$, meromorphic on $\mathbb{E}$, vanishes on it, so it vanishes.

(iv) Over $\mathbb{C}(\mathbb{E})$, with $\mathbf{d}$ the point of $\mathbb{E}$, the relations are those of the integrable connection $d + d\log(\omega_{\mathbf{d}}/dy)$ on the smooth affine variety X_W (proof of Theorem 48.3(iii)), and $\mathfrak{M}_{W,\mathbb{E}}$ is the top cohomology of its algebraic de Rham complex over a field of characteristic zero, finite-dimensional (proof of Theorem 47.4). The value of an element of $\mathcal{L}_W$ vanishes identically on $\mathbb{D}_W$ (Theorem 48.3(ii)), so that of an element of $\mathcal{L}_{\mathbb{E}}$ vanishes on $\mathbb{E}$, where the values of the insertions are meromorphic, $\mathbb{E}$ meeting the tube. $(c_e(\mathbf{d}) + \partial_{y_e})(f_{\mathbf{d}_1} g) = f_{\mathbf{d}_1}(c_e(\mathbf{d}+\mathbf{d}_1) + \partial_{y_e})g$ (proof of Theorem 48.3(iii)) and $\sigma_{\mathbf{d}_1}$ carries $\mathbb{C}(\mathbb{E})$ to itself, $\mathbf{d}_1$ lying in $\mathbb{E}$; so $\mathrm{Sh}_{\mathbf{d}_1}$ is a well-defined $\sigma_{\mathbf{d}_1}$-semilinear bijection of $\mathfrak{M}_{W,\mathbb{E}}$, with the inverse $\mathrm{Sh}_{-\mathbf{d}_1}$, and $\langle \mathrm{Sh}_{\mathbf{d}_1} x\rangle(\mathbf{d}) = \sum_l r_l(\mathbf{d}+\mathbf{d}_1)\langle f_{\mathbf{d}_1} g_l\rangle(\mathbf{d}) = \langle x\rangle(\mathbf{d}+\mathbf{d}_1)$. The span of the $\mathrm{Sh}^j x$, $j \geq 0$, has finite dimension; at the least h at which $\mathrm{Sh}^h x$ lies in the span of the earlier ones there is a law with $q_h = 1$, and $q_0 \neq 0$, since otherwise $\mathrm{Sh}_{-\mathbf{d}_1}$ would give a shorter one. Its certificate is a finite combination of elements of $\mathcal{L}_{\mathbb{E}}$; a search through the finite supports, each tested by one elimination over $\mathbb{C}(\mathbb{E})$, reaches one.

The value of the law at $p+k\mathbf{d}_1$ is $\sum_j q_j(p+k\mathbf{d}_1)\,\langle x\rangle\big(p+(k+j)\mathbf{d}_1\big) = 0$. The expansion of the j-th term is that of (ii) at $k+j$, times the expansion of $q_j(p+k\mathbf{d}_1)$; with $(k+j)^{\rho-i} = k^{\rho-i}\sum_b \binom{\rho-i}{b} j^b k^{-b}$, the expansion of the left side divided by $c_\star(\omega_p/dy)(\alpha^\star)(f^\star)^k k^{\rho+\nu'}$ is

$$\sum_{N\geq 0} k^{-N} \sum_{a+b+i=N} \binom{\rho-i}{b} \chi_{a,b}\, Q_i,$$

which is 0. Grouping by $s = a+b$, the coefficient of k^{-N} is $\sum_s C_s(N)\, Q_{N-s} = 0$ for every $N \geq 0$, with $Q_i = 0$ for $i < 0$. If every C_s were 0, then, $\binom{\rho-N+s}{b}$ having the degree b in N, comparing the powers of N from the top would give $\chi_{a,b} = 0$ for all a, b; then $\sum_j q_{j,a}(f^\star)^j j^b = 0$ for every b, and the Vandermonde matrix of the distinct $j = 0, \dots, h$ gives $q_{j,a} = 0$, so that every q_j would vanish along the line, against $q_0 \neq 0$ for p off a proper algebraic subset. With s_0 as stated, the equation at N reads $C_{s_0}(N) Q_{N-s_0} = -\sum_{s>s_0} C_s(N) Q_{N-s}$. For $N > N_0$, $C_{s_0}(N) \neq 0$, so Q_{N-s_0} is a combination of the Q_i with $i < N - s_0$; if these vanish up to $N_0 - s_0$, induction on N gives that all do. The integer roots of C_{s_0} are the integers at which a nonzero polynomial over $\mathbb{C}(\mathbb{E})$ vanishes, finitely many. □

Proposition 47.15 (The values separate the module). *As stated.*

Proof. The fibre of $\mathbb{D}_W$ over $\mathbf{w}$ is $\mathbf{m}_0(\mathbf{w}) + \vec{\mathcal{N}}_W \otimes \mathbb{C}$, $\mathbf{m}_0(\mathbf{w}) = \sum_i w_i \mathbf{t}_i$ (Definition 48.1(ii)), so π is onto, $\mathbb{E}$ is a linear subspace with $\pi(\mathbb{E}) = \mathbb{E}_{\mathbf{w}}$ whose fibres are those of $\mathbb{D}_W$, and the polynomials on $\mathbb{E}$ are the polynomials in the masses m_e, $e \in B$, with coefficients polynomials in the exponents, read on $\mathbb{E}$.

(i) Written out, $(c_e(\mathbf{d}) + \partial_{y_e}) g \otimes r = g \otimes m_e r - \sum_i R_{i,e}\, g \otimes w_i r + \partial_{y_e} g \otimes r$, the occupations $R_{i,e}$ and $\partial_{y_e} g$ being insertions (Definition 48.1(iii), (iv)); it lies in $\mathcal{L}_{\mathbb{E}}$, which is the identity. Let $x = \sum_l g_l \otimes r_l$, let $D \neq 0$ be a common denominator of the r_l, a polynomial on $\mathbb{E}$, and write every Dr_l as a polynomial in the masses with coefficients polynomials in the exponents. The identity, applied to $g \otimes m_e r$ with r a monomial in the masses times a polynomial in the exponents, replaces it by terms whose coefficients have one mass fewer; by induction on the degree in the masses, Dx is the class of an element $\sum_k G_k \otimes p_k$ as stated.

(ii) For $g \in \mathbb{C}[X_W]$ the value $\langle g\rangle$ is meromorphic on $\mathbb{D}_W$ with its poles on the hyperplanes $\kappa_v(\mathbf{d}) + \kappa_v(g) \in \{0, -1, -2, \dots\}$, v a generator (Theorem 48.3(ii)). None of them contains $\mathbb{E}$: the wall κ_v is a linear form with a positive real part at a point of $\mathbb{E} \cap \mathcal{T}_1$, so it is not constant on the linear space $\mathbb{E}$. So $\langle g\rangle$ restricts to a meromorphic function on $\mathbb{E}$, and the value of x on $\mathbb{E}$ is defined. At a point $\mathbf{d}$ of $\mathbb{E}$ the element $(c_e(\mathbf{d}) + \partial_{y_e}) g \otimes r$ has the value $r(\mathbf{d})\langle (c_e(\mathbf{d}) + \partial_{y_e}) g\rangle(\mathbf{d}) = 0$ (Theorem 48.3(ii)), so the value vanishes on $\mathcal{L}_{\mathbb{E}}$ and is defined on $\mathfrak{M}_{W,\mathbb{E}}$.

Let $\langle x\rangle = 0$ on $\mathbb{E}$, and let $Dx = [G]$, $G = \sum_k G_k \otimes p_k$ as in (i), with the G_k linearly independent over $\mathbb{C}$, each a finite combination of strides f_λ, $\lambda \in \mathbb{D}_W(\mathbb{Z})$ (Definition 48.1(iii)), and Λ the finite set of these λ. Then $\langle G\rangle = D\langle x\rangle = 0$ on $\mathbb{E}$, and $\langle G\rangle(\mathbf{d}) = \sum_k p_k(\mathbf{w})\langle G_k\rangle(\mathbf{d})$ converges absolutely on $\mathcal{T}_\Lambda = \bigcap_{\lambda\in\Lambda}(\mathcal{T}_1 - \lambda)$, $\langle f_\lambda\rangle(\mathbf{d})$ being $P_W(\mathbf{d}+\lambda)$ (Theorem 48.3(ii)). The walls are linear forms with real coefficients (Lemma 48.2(ii)), so for $\mathbf{d} \in \mathbb{E}\cap\mathcal{T}_1$ and real $t > 0$, $\operatorname{Re}\kappa_v(t\mathbf{d}) = t\operatorname{Re}\kappa_v(\mathbf{d})$, $t\mathbf{d} \in \mathcal{T}_\Lambda$ for t large, and $\mathbb{E}\cap\mathcal{T}_\Lambda$ is a nonempty open subset of $\mathbb{E}$. Its image U under π, a linear map of $\mathbb{E}$ onto $\mathbb{E}_\mathbf{w}$, is a nonempty open subset of $\mathbb{E}_\mathbf{w}$. Fix $\mathbf{w} \in U$. The points of the fibre $\mathbf{m}_0(\mathbf{w}) + \vec{\mathcal{N}}_W \otimes \mathbb{C}$ that lie in $\mathcal{T}_\Lambda$ are those whose masses have their real parts in a nonempty open set, cut out by the strict linear inequalities $\operatorname{Re}\kappa_v(\mathbf{m};\mathbf{w}) + \kappa_v(\lambda) > 0$; fix such a point $\mathbf{d}^\circ = (\mathbf{m}^\circ;\mathbf{w})$ and move it by $(i\tau;\mathbf{0})$, $\tau \in \vec{\mathcal{N}}_W$, which keeps the real parts. The pairing of $\vec{\mathcal{N}}_W$ with $V_W = \mathbb{R}^B/\vec{\mathcal{N}}_W^\perp$ is perfect, and $\omega_{\mathbf{d}^\circ+(i\tau;\mathbf{0})} = e^{i\langle\tau,y\rangle}\,\omega_{\mathbf{d}^\circ}$, so

$$0 = \langle G\rangle\big(\mathbf{d}^\circ + (i\tau;\mathbf{0})\big) = \int_{V_W} e^{i\langle\tau,y\rangle}\,h(y)\,dy, \qquad h = G(\cdot;\mathbf{w})\,\frac{\omega_{\mathbf{d}^\circ}}{dy}, \quad G(\cdot;\mathbf{w}) = \sum_k p_k(\mathbf{w})\,G_k,$$

for every $\tau \in \vec{\mathcal{N}}_W$, with h integrable on V_W, every term converging absolutely. This is the Fourier transform of h on V_W; so $h = 0$ almost everywhere and, h being continuous, everywhere. The density $\omega_{\mathbf{d}^\circ}/dy$ has no zero on V_W, the letters being positive there and the powers principal, so $G(\cdot;\mathbf{w})$ vanishes at the positive points of X_W, the image of the positive orthant. The quotient T_W of $(\mathbb{C}^\times)^B$ by the subtorus of Definition 48.1(iii) is a torus with the coordinates $\alpha^{u_1},\dots,\alpha^{u_{r_W}}$, u_k a basis of M_W, a lattice that is saturated in $\mathbb{Z}^B$; the functions $\ell_i = \alpha^{-\mathbf{t}_i}L_i$ are regular on it, X_W is the set on which none vanishes, and a regular function on X_W is $P\prod_i \ell_i^{-a_i}$ with P a Laurent polynomial in these coordinates. The positive points are those at which every coordinate is positive, where no ℓ_i vanishes, and a Laurent polynomial that vanishes there is 0. So $G(\cdot;\mathbf{w}) = 0$ in $\mathbb{C}[X_W]$ for every $\mathbf{w} \in U$; the G_k being independent, every p_k vanishes on U, and a polynomial on $\mathbb{E}_\mathbf{w}$ that vanishes on a nonempty open set is 0. So $G = 0$, $Dx = 0$, and $x = 0$, D being invertible in $\mathbb{C}(\mathbb{E})$.

The rest of (ii) follows: a combination of insertions of value zero is 0 in $\mathfrak{M}_{W,\mathbb{E}}$, that is, it lies in $\mathcal{L}_\mathbb{E}$; for insertions g and g', $\langle g\rangle = \langle g'\rangle$ exactly when $\langle[g-g']\rangle = 0$; and a relation $\sum_l r_l\langle b_l\rangle = 0$ is the value zero of $\sum_l r_l[b_l]$.

(iii) $\mathbb{D}_W = \pi^{-1}(\mathbb{C}^I)$ meets $\mathcal{T}_1$ (Theorem 48.3(i)), so (ii) gives $\operatorname{Ann}\langle\cdot\rangle = 0$, and a submodule of elements of value zero is 0. By Theorem 47.4(v), with Theorem 48.3(iii), $\langle g\rangle = \langle g'\rangle$ exactly when the reductions agree, and the values of masters are independent by (ii). For a family of letters of tables, Theorem 47.11 and Proposition 47.12 hold for $\mathfrak{M}_W$ (Theorem 48.23(ii)), so the elements whose closings vanish along those rays are the elements of value zero, which are 0.

(iv) A native direction has every wall positive, so it lies in $\mathcal{T}_1$ and $\mathbb{E}$ meets the tube. By Proposition 47.14(iii), (iv), the value of x on $\mathbb{E}$ vanishes exactly when finitely many of its coefficients Q_i do, and by (ii) it vanishes exactly when $x = 0$. □

Proposition 47.16 (The number of masters). *As stated.*

Proof. Coordinates. Let $u_1,\dots,u_r$ be a basis of M_W, $z_k = \alpha^{u_k}$ the coordinates of the quotient torus T_W (proof of Proposition 47.15), $Y_k = \log z_k$ and $\theta_k = z_k\partial_{z_k}$, so that $\partial_{y_e} = \sum_k (u_k)_e\theta_k$ on the insertions. Write $\mathbf{m} - \sum_i w_i\mathbf{t}_i = \sum_k \mu_k u_k$ on $\mathbb{D}_W$ (Definition 48.1(ii)): $(\boldsymbol{\mu};\mathbf{w})$ are linear coordinates on $\mathbb{D}_W$, and $\omega_\mathbf{d}/dy = \prod_k z_k^{\mu_k}\prod_i \ell_i^{-w_i}$ with $\ell_i = \alpha^{-\mathbf{t}_i}L_i$. With the insertions $\rho_{i,k} = \theta_k\ell_i/\ell_i$, $R_{i,e} = (\mathbf{t}_i)_e + \sum_k (u_k)_e\rho_{i,k}$, so $c_e(\mathbf{d}) = \sum_k (u_k)_e\,x_k$ with $x_k = \mu_k - \sum_i w_i\rho_{i,k}$, the defect in the coordinate k. The forms of X_W have the frame of the dY_J, and the differential is $\sum_k dY_k\wedge(\theta_k + x_k)$: the twisted de Rham complex is the Koszul complex of the operators $D_k = \theta_k + x_k = P_k + \mu_k$,

$P_k = \theta_k - \sum_i w_i \rho_{i,k}$, on $\mathbb{C}[X_W]$, and these commute, $\theta_k \rho_{i,l} = \theta_l \rho_{i,k}$. The $c_e(\mathbf{d}) + \partial_{y_e} = \sum_k (u_k)_e D_k$ span the same space as the D_k, the u_k being independent, so the top cohomology over $\mathbb{K}_W$ is $\mathfrak{M}_W$.

(i) Let $A = \mathbb{C}[\boldsymbol{\mu}, \mathbf{w}]$, the polynomials on $\mathbb{D}_W$, and $F = \mathbb{C}[X_W] \otimes A$, a free A-module on which the D_k act A-linearly. For $j = 0, \dots, r$ let $F_j = \mathbb{C}[X_W] \otimes \mathbb{C}[\mathbf{w}][\mu_{j+1}, \dots, \mu_r]$, $F_0 = F$. The map $F_{j-1} \to F_j$ that puts $-P_j$ in the place of μ_j, $\sum_a g_a \mu_j^a \mapsto \sum_a (-P_j)^a g_a$, is onto, and its kernel is $D_j F_{j-1}$: the map kills $D_j F_{j-1}$, carrying $D_j(g\mu_j^a) = (P_j g)\mu_j^a + g\mu_j^{a+1}$, $g \in F_j$, to $(-P_j)^a P_j g + (-P_j)^{a+1} g = 0$, and $g\mu_j^a - (-P_j)^a g = D_j \sum_{b<a} (-P_j)^b \mu_j^{a-1-b} g$. As P_j commutes with the P_k and the μ_k, $k > j$, the map carries D_k on F_{j-1} to D_k on F_j for $k > j$. D_j is injective on F_{j-1}, the top power of μ_j in $D_j g$ being μ_j times that of g. By induction $F_j = F/(D_1, \dots, D_j)F$, with D_{j+1} injective on it, so $D_1, \dots, D_r$ is a regular sequence on F: its Koszul complex is exact but at the top, where it has $N = F/(D_1, \dots, D_r)F \cong \mathbb{C}[X_W] \otimes \mathbb{C}[\mathbf{w}]$, μ_k acting by $-P_k$. The complex over $\mathbb{K}_W$ is its localization at the nonzero elements of A, which keeps exactness; so $H^i(\mathbb{K}_W) = 0$ for $i < r$, and $\mathfrak{M}_W = N \otimes_A \mathbb{K}_W$.

At $\mathbf{d} \in \mathbb{D}_W$ the complex is the Koszul complex over A, a free resolution of N, tensored with $\mathbb{C}_\mathbf{d} = A/\mathfrak{m}_\mathbf{d}$, so $H^{r-j}(\mathbf{d}) = \operatorname{Tor}_j^A(N, \mathbb{C}_\mathbf{d})$. N has a countable basis over $\mathbb{C}$, the strides spanning $\mathbb{C}[X_W]$; let N_n be the A-submodule generated by its first n elements, finitely generated, so that $N = \bigcup_n N_n$. A finitely generated A-module becomes free when one nonzero element of A is inverted: it has a filtration with the quotients $A/\mathfrak{p}$, $\mathfrak{p}$ prime, and once the product of one nonzero element of each $\mathfrak{p} \neq 0$ is inverted, the quotients with $\mathfrak{p} \neq 0$ vanish and the others are free, so that the module, built from free modules by extensions, is free. Let s_1 do this for N_1 and s_{n+1} for N_{n+1}/N_n. At $\mathbf{d}$ off the hypersurfaces $s_n = 0$ the localizations at $\mathbf{d}$ of N_1 and of the N_{n+1}/N_n are free, so are those of the N_n, and the inclusions $N_n \subseteq N_{n+1}$ stay injective after $\otimes \mathbb{C}_\mathbf{d}$. Tor commutes with the increasing union, so $\operatorname{Tor}_j(N, \mathbb{C}_\mathbf{d}) = 0$ for $j \geq 1$, and $N \otimes \mathbb{C}_\mathbf{d}$ is the increasing union of the $N_n \otimes \mathbb{C}_\mathbf{d}$, of the dimensions $\operatorname{rank} N_n$, whose limit is $\operatorname{rank} N = \dim_{\mathbb{K}_W} N \otimes_A \mathbb{K}_W = \mathfrak{m}_W$. On a line that lies in no hypersurface $s_n = 0$, localize at its generic point instead: no s_n vanishes there, and the same argument over the local ring of the line gives the dimension $\mathfrak{m}_W$ over its field of rational functions; N tensored with that field is the quotient of $\mathbb{C}[X_W]$ over it by the D_k read on the line, the module restricted to the line (Proposition 47.5).

(ii) At every $\mathbf{d}$ the connection $d + d\log(\omega_\mathbf{d}/dy)$ has regular singularities at infinity: near a point of the boundary of a compactification of X_W by a divisor with normal crossings, its form is a combination with constant coefficients of the $d\log$ of the local equations of the boundary components, plus a regular form, $\omega_\mathbf{d}/dy$ being a product of complex powers of the z_k and the ℓ_i, units on X_W. For such a connection the algebraic de Rham cohomology is the cohomology of $X_W(\mathbb{C})$ with coefficients in the local system $L_\mathbf{d}$ of its horizontal sections (the comparison theorem for connections with regular singularities), here the constant multiples of the local branches of $(\omega_\mathbf{d}/dy)^{-1}$, a local system of rank one. In the terms of the values: a cycle of the dual system is a chain that carries a branch of $\omega_\mathbf{d}/dy$, over which an insertion is integrated, and the comparison says that the classes of $H^r(\mathbf{d})$ are told apart by their integrals over the compact such cycles; the positive orthant with the principal branch, over which the integrals are the values, is such a cycle with a support that is closed but not compact. $X_W(\mathbb{C})$, a smooth affine variety, has the homotopy type of a finite cell complex, and the cochains of a local system of rank one on it have one generator for each cell; so $\sum_i (-1)^i \dim H^i(\mathbf{d}) = \operatorname{eu}(X_W)$ at every $\mathbf{d}$. There are $\mathbf{d}$ off the hypersurfaces of (i), a countable union of proper hypersurfaces having no interior point, and at them only $H^r(\mathbf{d})$ is not 0, of the dimension $\mathfrak{m}_W$, so $\mathfrak{m}_W = (-1)^r \operatorname{eu}(X_W)$.

(iii) *The native variety.* In the coordinates the native points of $\mathbf{d}$ are the points of X_W at which every x_k vanishes, $\mu_k = \sum_i w_i \rho_{i,k}$. So the set Z of the pairs $(\alpha, \mathbf{d})$ with α native for $\mathbf{d}$ is the graph of $(\alpha, \mathbf{w}) \mapsto \big((\sum_i w_i \rho_{i,k}(\alpha))_k; \mathbf{w}\big)$, isomorphic to $X_W \times \mathbb{C}^I$, smooth and irreducible of the dimension

of $\mathbb{D}_W$, with the coordinate ring $N_0 = \mathbb{C}[X_W] \otimes \mathbb{C}[\mathbf{w}]$, μ_k acting by $\sum_i w_i \rho_{i,k}$. At a native point the differential of the projection $\pi : Z \to \mathbb{D}_W$ is invertible exactly when the Hessian of $\log(\omega_{\mathbf{d}}/dy)$ in the coordinates Y is, that is when the point is nondegenerate. At a positive point with every exponent positive the Hessian is definite, $\log(\omega_{\mathbf{d}}/dy) = \langle \boldsymbol{\mu}, Y\rangle - \sum_i w_i \log \ell_i$ being strictly concave there, as the differences of the exponents of the letters span $\vec{\mathcal{N}}_W$; so π is dominant, its generic fibre is finite, of a degree ν_W, and reduced, and off a proper algebraic subset of $\mathbb{D}_W$ the native points are ν_W in number and nondegenerate. $N_0 \otimes_A \mathbb{K}_W$, the ring of the generic fibre, has the dimension ν_W over $\mathbb{K}_W$.

At least one master for each native point. Let $\hbar$ be one more variable and $\mathcal{M}$ the quotient of $\mathbb{C}[X_W] \otimes A[\hbar]$ by the operators $\hbar\theta_k + x_k$, which commute. By the argument of (i), with $\hbar\theta_k$ in the place of θ_k, $\mathcal{M} \cong \mathbb{C}[X_W] \otimes \mathbb{C}[\mathbf{w}, \hbar]$, μ_k acting by $-(\hbar\theta_k - \sum_i w_i \rho_{i,k})$, a free $\mathbb{C}[\hbar]$-module. Let $L = \mathcal{M} \otimes_A \mathbb{K}_W$, a module over $\mathbb{K}_W[\hbar]$ on which $\hbar$ is injective: an element killed by $\hbar$ once some $s \in A \setminus \{0\}$ is inverted is killed by s, $\hbar$ being injective on $\mathcal{M}$ and commuting with s. Then $L/\hbar L = N_0 \otimes_A \mathbb{K}_W$, of the dimension ν_W; and $L \otimes \mathbb{K}_W(\hbar)$, the quotient of $\mathbb{C}[X_W] \otimes \mathbb{C}(\hbar, \boldsymbol{\mu}, \mathbf{w})$ by the $\hbar\theta_k + x_k(\boldsymbol{\mu}, \mathbf{w}) = \hbar\big(\theta_k + x_k(\boldsymbol{\mu}/\hbar, \mathbf{w}/\hbar)\big)$, is $\mathfrak{M}_W$ read through the automorphism $(\boldsymbol{\mu}, \mathbf{w}) \mapsto (\boldsymbol{\mu}/\hbar, \mathbf{w}/\hbar)$ of that field, of the dimension $\mathfrak{m}_W$. Over the discrete valuation ring $\mathbb{K}_W[\hbar]_{(\hbar)}$ the localization of L is torsion free with the same quotient by $\hbar$, and elements independent modulo $\hbar$ are independent: a relation among them, divided by the largest power of $\hbar$ that divides all its coefficients, reduces to a relation modulo $\hbar$. So $\nu_W \le \mathfrak{m}_W$. At $\hbar = 0$ the module is the functions on the native points, and the data $\mathbf{d}/\hbar$ run out along the direction $\mathbf{d}$ as $\hbar \to 0$.

Exactly one. X_W is a smooth very affine variety, a closed subvariety of the torus $T_W \times (\mathbb{C}^\times)^I$ as the graph of the ℓ_i, and $\omega_{\mathbf{d}}/dy$ is the restriction of $\prod_k z_k^{\mu_k} \prod_i t_i^{-w_i}$, a character of that torus when $\mathbf{d}$ is integral, M_W being saturated; so its native points are the zeros on X_W of the restriction of the invariant form $\sum_k \mu_k \, d\log z_k - \sum_i w_i \, d\log t_i$. For integral $\mathbf{d}$ off a hypersurface of $\mathbb{D}_W$ these zeros are nondegenerate and $(-1)^r \operatorname{eu}(X_W)$ in number, by Huh's theorem on the critical points of a generic master function of a smooth very affine variety, whose exponents are integral: the zeros of a generic logarithmic form are counted by the Euler characteristic, as the zeros of a generic vector field on a compact manifold are. The integral data are Zariski dense in $\mathbb{D}_W$, so one of them lies off that hypersurface and off the proper algebraic subset over which the native points are ν_W in number and nondegenerate: $\nu_W = (-1)^r \operatorname{eu}(X_W)$. This is the count of Theorem 38.31(i) for a family of tables. With (ii), $\nu_W = \mathfrak{m}_W$.

At most $\mathfrak{m}_W$ at every data. At a nondegenerate native point of $\mathbf{d}$ the differential of π is invertible, so near that point π^{-1} has a holomorphic sheet through it, and the sheets through distinct nondegenerate native points of $\mathbf{d}$ are disjoint near $\mathbf{d}$. Data near $\mathbf{d}$ off the proper algebraic subset have a native point on each sheet, and they have $\nu_W = \mathfrak{m}_W$; so the nondegenerate native points of $\mathbf{d}$ are at most $\mathfrak{m}_W$. The native gauges of a direction are its native points (Definition 38.4), and the rest of (iii) follows.

(iv) A set of insertions whose classes span a space of the dimension $\mathfrak{m}_W$ has at least $\mathfrak{m}_W$ elements, and by (iii) the nondegenerate native points of any data are at most $\mathfrak{m}_W$; so a spanning set with at most as many elements as these points has $\mathfrak{m}_W$ elements and is a basis. For a box, Theorem 47.8(i) then gives $\mathbf{B}_\mu = \mathbf{A}_{-\mu}$. For an accepted set the module presented is $\mathfrak{M}_W$ (Theorem 48.18(iv), Proposition 47.15), of the dimension $\mathfrak{m}_W$, a quotient of $\mathbb{K}_W^\Lambda$ of the same dimension, so $\mathfrak{N} = 0$. □

50.47 Chapter 48: the module along the tree

Definition 48.1 (A family of positive letters). As stated.

Proof. (i) The exponents of the support of a letter have one total, its degree, so their differences lie in $\mathbf{1}^\perp$. A constant letter has the one exponent $\mathbf{0}$: it adds nothing to $\vec{\mathcal{N}}_W$, its occupations vanish, its term in a wall is 0, and below its polynomial $k_{i,\pi}$ is its value. The space of the directions of a Minkowski sum $\sum_i w_i\mathcal{N}_{L_i}$ with every $w_i > 0$ is the sum of the spaces of the directions of its terms, each spanned by the differences of the exponents of a support.

(ii) Another exponent $\mathbf{t}'_i$ of the support of L_i has $\mathbf{t}'_i - \mathbf{t}_i \in \vec{\mathcal{N}}_W$, so the condition does not change. For a full family $\vec{\mathcal{N}}_W \otimes \mathbb{C} = \mathbf{1}^\perp$, and the condition is $m_B = \sum_i w_i|\mathbf{t}_i| = \sum_i w_i \deg L_i$.

(iii) M_W is the set of the integral points of a rational subspace, so it is saturated, and the subtorus H on which every α^u, $u \in M_W$, is 1 is a torus of dimension $|B| - r_W$ whose characters trivial on it are exactly the α^u, $u \in M_W$. For an exponent $\mathbf{t}$ of the support of L_i and $\zeta \in H$, $\zeta^{\mathbf{t}} = \zeta^{\mathbf{t}_i}\zeta^{\mathbf{t}-\mathbf{t}_i} = \zeta^{\mathbf{t}_i}$, so $L_i(\zeta\alpha) = \zeta^{\mathbf{t}_i}L_i(\alpha)$, and the set Y on which no letter vanishes is stable. The quotient $(\mathbb{C}^\times)^B/H$ is a torus of dimension r_W with the regular functions $\mathbb{C}[M_W]$, and $X_W = Y/H$ is its open subset where the invariant Laurent polynomial $\prod_i \alpha^{-\mathbf{t}_i}L_i$ does not vanish: smooth and affine, of dimension r_W, its regular functions the invariants of $\mathbb{C}[Y] = \mathbb{C}[\alpha^{\pm1}][\prod_i L_i^{-1}]$. Every element of $\mathbb{C}[Y]$ is a sum of elements $\alpha^u \prod_i L_i^{-a_i}$, $\mathbf{a} \in \mathbb{N}^I$, each semi-invariant with the character $\alpha^{u-\sum_i a_i\mathbf{t}_i}$, which is trivial on H exactly when $u - \sum_i a_i\mathbf{t}_i \in M_W$, that is when $(u;\mathbf{a}) \in \mathbb{D}_W(\mathbb{Z})$; so the invariants are the stated span. For $\lambda = (v;\mathbf{a}) \in \mathbb{D}_W(\mathbb{Z})$ with $\mathbf{a} \in \mathbb{Z}^I$, expanding the powers $L_i^{-a_i}$ with $a_i < 0$ writes f_λ as a sum of the $\alpha^{v+\mathbf{t}}\prod_{a_i>0} L_i^{-a_i}$, $\mathbf{t}$ a sum of $-a_i$ exponents of the support of each L_i with $a_i < 0$, whose data are integral points of $\mathbb{D}_W$, the vector $\mathbf{t} - \sum_{a_i<0}(-a_i)\mathbf{t}_i$ lying in M_W; so $f_\lambda \in \mathbb{C}[X_W]$, and $f_\lambda f_{-\lambda} = 1$.

(iv) $V_W(\mathbb{Z})$ is a lattice of full rank in V_W, $\vec{\mathcal{N}}_W^\perp$ being rational. For $v \in \vec{\mathcal{N}}_W^\perp$ every exponent $\mathbf{t}$ of L_i has $\langle\mathbf{t}, v\rangle = \langle\mathbf{t}_i, v\rangle$, so $L_i(e^{y+v}) = e^{\langle\mathbf{t}_i,v\rangle}L_i(e^y)$, the logarithms being real, and the density at $y+v$ is $e^{\langle\mathbf{m}-\sum_i w_i\mathbf{t}_i,v\rangle}$ times that at y, which is the density at y on $\mathbb{D}_W$. Integral powers of the positive $L_i(e^y)$ multiply the principal ones, so $f_\lambda\,\omega_{\mathbf{d}} = \omega_{\mathbf{d}+\lambda}$. $R_{i,e} = \sum_{\mathbf{t}} c_{i,\mathbf{t}}t_e\,\alpha^{\mathbf{t}}/L_i$ is a combination of the insertions $\alpha^{\mathbf{t}}/L_i$, whose data $(\mathbf{t};\mathbf{e}_i)$ lie in $\mathbb{D}_W(\mathbb{Z})$; on the orthant $0 \le t_e \le |\mathbf{t}| = \deg L_i$ and the $c_{i,\mathbf{t}}\alpha^{\mathbf{t}}$ are positive, so $0 \le R_{i,e} \le \deg L_i$. $\partial_{y_e}\log(\omega_{\mathbf{d}}/dy) = m_e - \sum_i w_i\alpha_e\partial_{\alpha_e}L_i/L_i = c_e(\mathbf{d})$, and the same computation with the data of λ gives $c_e(\lambda)$. For $v \in \vec{\mathcal{N}}_W^\perp$, $\sum_e v_e\alpha_e\partial_{\alpha_e}\alpha^{\mathbf{t}} = \langle\mathbf{t}, v\rangle\alpha^{\mathbf{t}} = \langle\mathbf{t}_i, v\rangle\alpha^{\mathbf{t}}$ on the support of L_i, so $\sum_e v_eR_{i,e} = \langle\mathbf{t}_i, v\rangle$ and $\sum_e v_ec_e(\mathbf{d}) = \langle\mathbf{m} - \sum_i w_i\mathbf{t}_i, v\rangle = 0$.

(v) For a full family $\vec{\mathcal{N}}_W^\perp = \mathbb{R}\mathbf{1}$, V_W is identified with the chart $\{y_{e_0} = 0\}$, whose integral points are the image of $\mathbb{Z}^B$ and whose Lebesgue measure $\prod_{e\ne e_0} dy_e$ gives them the covolume one, and $\int e^{\langle\mathbf{m},y\rangle}W(\mathbf{w})(e^y)\prod_{e\ne e_0} dy_e$ is the integral of $\alpha^{\mathbf{m}-\mathbf{1}}W(\mathbf{w})\,d\alpha$ over the section $\alpha_{e_0} = 1$, the period (Definition 25.1, Lemma 16.2). For every family the integral over $\mathbb{R}^B/\vec{\mathcal{N}}_W^\perp$ with this measure is the reduced period of Theorem 28.12 by its definition. □

Lemma 48.2 (The fan of a family of positive letters). *As stated.*

Proof. The differences of the exponents of one letter lie in $\vec{\mathcal{N}}_W$, which is the dual of V_W, so the pairings below are well defined.

(i) For each i and each exponent $\mathbf{t}$ of the support of L_i the set $C_{i,\mathbf{t}} = \{v \in V_W :\ \langle\mathbf{t} - \mathbf{t}', v\rangle \le 0\ \forall\mathbf{t}'\}$ is a rational polyhedral cone, and these cones form the inner normal fan of $\mathcal{N}_{L_i}$ read in V_W, which covers V_W, every v having an exponent of least pairing. The cones $\bigcap_i C_{i,\mathbf{t}_i}$, one exponent for each letter, with their faces, form a fan covering V_W, the common refinement, and each is pointed: a line $\mathbb{R}v$ in it has $\langle\mathbf{t} - \mathbf{t}', v\rangle = 0$ for any two exponents of every letter, so v vanishes on $\vec{\mathcal{N}}_W$ and is 0 in V_W. Triangulating these cones by pulling, as in the proof of Lemma S14(i), gives finitely many rational simplicial cones of dimension r_W with disjoint interiors covering V_W, with their faces a fan, each in some $\bigcap_i C_{i,\mathbf{t}_i}$. A face of a Minkowski sum $\sum_i w_i\mathcal{N}_{L_i}$, $w_i > 0$, is the sum of the faces of the terms on which one linear form is least, so the inner normal fan of the sum is

the common refinement of those of the terms, and every cone of a fan of W lies in a cone of it. Let ρ be a ray of the inner normal fan Σ' of the sum and p a point of its relative interior. Then p lies in the relative interior of some cone σ of the fan of W, and σ lies in a cone τ of Σ'; $\tau\cap\rho$ is a face of ρ containing p, so ρ is a face of τ, and a convex subset of τ whose relative interior meets the face ρ lies in ρ. So $\sigma=\rho$, and ρ is a ray of the fan of W.

(ii) Replacing $\mathbf{t}_i$ by $\mathbf{t}_i'$ subtracts $w_i\langle\mathbf{t}_i'-\mathbf{t}_i,v\rangle$ from the first term and adds it to the second. For a cone π with the generator v, $\mathbf{t}_{i,\pi}$ pairs least with every point of π, so $\min_{\mathbf{t}}\langle\mathbf{t}-\mathbf{t}_i,v\rangle=\langle\mathbf{t}_{i,\pi}-\mathbf{t}_i,v\rangle$ and $\kappa_v(\mathbf{d})=\langle\mathbf{m}-\sum_i w_i\mathbf{t}_{i,\pi},v\rangle$, which therefore does not depend on π. On $\mathbb{D}_W(\mathbb{Z})$ the vectors $\mathbf{m}-\sum_i w_i\mathbf{t}_i$ and $\mathbf{t}-\mathbf{t}_i$ lie in M_W, which pairs integrally with $V_W(\mathbb{Z})$.

(iii) Two exponents that pair least with every generator of π have a difference in $\vec{\mathcal{N}}_W$ that vanishes on a basis of V_W, so they are equal. The exponents $\langle\mathbf{t}-\mathbf{t}_{i,\pi},v_{\pi,k}\rangle$ are integers, by (ii), and nonnegative by the choice of $\mathbf{t}_{i,\pi}$, and all of them vanish only at $\mathbf{t}=\mathbf{t}_{i,\pi}$; so $k_{i,\pi}$ is a polynomial with nonnegative coefficients and the constant term $c_{i,\mathbf{t}_{i,\pi}}$. For $x\in\vec{\mathcal{N}}_W\otimes\mathbb{C}$ and $y=-\sum_k u_k v_{\pi,k}$, $e^{\langle x,y\rangle}=\prod_k q_k^{\langle x,v_{\pi,k}\rangle}$, and on a lift of y to $\mathbb{R}^B$, $L_i(e^y)=e^{\langle\mathbf{t}_{i,\pi},y\rangle}k_{i,\pi}(q)$; so

$$g\,\omega_{\mathbf{d}}/dy=e^{\langle\mathbf{m}+u-\sum_i(w_i+a_i)\mathbf{t}_{i,\pi},y\rangle}\prod_i k_{i,\pi}(q)^{-w_i-a_i}=\prod_k q_k^{\kappa_{v_{\pi,k}}(\mathbf{d})+\kappa_{v_{\pi,k}}(g)}\prod_i k_{i,\pi}(q)^{-w_i-a_i},$$

the exponent being $\kappa_{v_{\pi,k}}$ at the data $\mathbf{d}+(u;\mathbf{a})$, by (ii) and linearity. The map $(u_k)_k\mapsto-\sum_k u_k v_{\pi,k}$ is a linear bijection of $[0,\infty)^{r_W}$ onto $-\pi$ with the Jacobian $|\det(v_{\pi,1},\dots,v_{\pi,r_W})|$ for the measure dy, and $du_k=-dq_k/q_k$. The cones $-\pi$ cover V_W with null boundaries and disjoint interiors, and the integrands are positive at real data, so the two sides agree in $[0,\infty]$ by Tonelli's theorem. On $[0,1]^{r_W}$ each $k_{i,\pi}$ lies between its constant term and the sum of its coefficients, so $\prod_i k_{i,\pi}^{-w_i-a_i}$ is bounded above and below by positive constants, and the cube integral is finite exactly when every exponent $\kappa_{v_{\pi,k}}(\mathbf{d})+\kappa_{v_{\pi,k}}(g)$ is positive; every generator is a generator of some cone. At $r_W=0$ the only cone is $\{0\}$, the measure is the unit mass and every letter is a monomial, and both sides are the density at the point.

For complex $\mathbf{d}$, g is positive on the real points and $|L_i(e^y)^{-w_i}|=L_i(e^y)^{-\operatorname{Re}w_i}$, so $|g\,\omega_{\mathbf{d}}|=g\,\omega_{\operatorname{Re}\mathbf{d}}$, and $\langle g\rangle(\mathbf{d})$ converges absolutely exactly when $\operatorname{Re}\mathbf{d}\in\mathcal{T}_g$, by (iii); this set is defined by the convergence, so it does not depend on the fan. □

Theorem 48.3 (The module of a family of positive letters). *As stated.*

Proof. (i) At positive real exponents $\sum_i w_i\min_{\mathbf{t}}\langle\mathbf{t}-\mathbf{t}_i,v\rangle$ is the least value of $\langle\cdot,v\rangle$ on $P_{\mathbf{w}}=\sum_i w_i(\mathcal{N}_{L_i}-\mathbf{t}_i)$, the least value of a linear form on a Minkowski sum being the sum of its least values on the terms; so $\kappa_v(\mathbf{d})=\langle p,v\rangle-\min_{P_{\mathbf{w}}}\langle\cdot,v\rangle$ with $p=\mathbf{m}-\sum_i w_i\mathbf{t}_i\in\vec{\mathcal{N}}_W$. $P_{\mathbf{w}}$ is a polytope in $\vec{\mathcal{N}}_W$ of the dimension r_W, its space of directions being $\vec{\mathcal{N}}_W$ (proof of Definition 48.1(i)). The inner normals of its facets lie on the rays of its inner normal fan in the dual V_W, which are rays of the fan (Lemma 48.2(i)), so their primitive vectors are generators. So every wall is positive exactly when p lies strictly inside every facet, that is in the interior of $P_{\mathbf{w}}$ in $\vec{\mathcal{N}}_W$, an interior point having $\langle p,v\rangle>\min_{P_{\mathbf{w}}}\langle\cdot,v\rangle$ for every $v\neq0$; with Lemma 48.2(iii) at $g=1$ this is the criterion. $P_{\mathbf{1}}=\sum_i(\mathcal{N}_{L_i}-\mathbf{t}_i)$ is a lattice polytope of $M_W\otimes\mathbb{R}$, its vertices being sums of differences of exponents, of the dimension r_W, so it contains r_W+1 affinely independent points $p_0,\dots,p_{r_W}$ of M_W, and $p_*=\sum_k p_k$, all of whose barycentric coordinates in the simplex $\operatorname{conv}\{(r_W+1)p_k\}$ are $(r_W+1)^{-1}$, is a point of M_W in the interior of $(r_W+1)P_{\mathbf{1}}=P_{(r_W+1)\mathbf{1}}$. With $n=r_W+1$, $\mathbf{d}_1=(p_*+n\sum_i\mathbf{t}_i;\,n\mathbf{1})$ lies in $\mathbb{D}_W(\mathbb{Z})$, has every exponent $n\geq1$, and has every wall positive by the criterion. The walls are linear, so $\kappa_v(\eta\,\mathbf{d}_1)=\eta\,\kappa_v(\mathbf{d}_1)>0$.

(ii) *Convergence and the relations.* By Lemma 48.2(iii) and its last paragraph $\langle g\rangle(\mathbf{d})$ converges absolutely on $\mathcal{T}_g$. On the orthant $|c_e(\mathbf{d})| \le |m_e| + \sum_i |w_i| \deg L_i$ and $\partial_{y_e} g = g\,(u_e - \sum_i a_i R_{i,e})$, so $|(c_e(\mathbf{d}) + \partial_{y_e})g| \le C\,|g|$ and the value of $(c_e(\mathbf{d}) + \partial_{y_e})g$ converges absolutely on $\mathcal{T}_g$ as well. Its integrand is the derivative of $\phi = g\,\omega_{\mathbf{d}}/dy$ along the image $\bar e$ of $\mathbf{e}_e$ in V_W, a C^1 function that is integrable on V_W together with its derivative along $\bar e$. If $\bar e = 0$ that derivative vanishes. Otherwise write $V_W = \mathbb{R}\bar e \oplus V'$; for almost every $y' \in V'$ the function $s \mapsto \phi(y' + s\bar e)$ and its derivative are integrable on $\mathbb{R}$, so it has limits at $\pm\infty$, which vanish, and the integral of its derivative is 0; by Fubini's theorem $\langle (c_e(\mathbf{d}) + \partial_{y_e})g\rangle(\mathbf{d}) = 0$. The integrals $\int f_\lambda g\,\omega_{\mathbf{d}}$ and $\int g\,\omega_{\mathbf{d}+\lambda}$ have one integrand.

Continuation. By Lemma 48.2(iii), for $\mathbf{d} \in \mathcal{T}_g$,

$$\langle g\rangle(\mathbf{d}) = \sum_\pi |\det(v_{\pi,1}, \dots, v_{\pi,r_W})| \int_{[0,1]^{r_W}} \prod_k q_k^{x_k(\mathbf{d})-1} h_\pi(q, \mathbf{d})\, dq$$

with $x_k = \kappa_{v_{\pi,k}}(\mathbf{d}) + \kappa_{v_{\pi,k}}(g)$ and $h_\pi = \prod_i k_{i,\pi}^{-w_i - a_i}$: the absolute convergence on $\mathcal{T}_g$ is that of Lemma 48.2(iii) at $\operatorname{Re}\mathbf{d}$. The $k_{i,\pi}$ have positive real parts on a neighbourhood of the cube, where their principal logarithms are holomorphic, so h_π is smooth in q near the cube, with q-derivatives continuous in $(q, \mathbf{d})$ and entire in $\mathbf{d}$. Lemma 8.4, with the data $\mathbf{d}$ as its parameter, continues each term meromorphically in $(x, \mathbf{d})$, with poles on the hyperplanes $x_k \in -\mathbb{N}$, and on $\{\operatorname{Re} x_k > -N_0\ \forall k\}$ writes it as a finite sum of products of factors $(x_k + h)^{-1}$, $0 \le h < N_0$, with holomorphic functions. Each x_k is an affine function of $\mathbf{d}$ that is not constant: at the data $(\mathbf{m}; \mathbf{0})$, $\mathbf{m} \in \vec{\mathcal{N}}_W \otimes \mathbb{C}$, which lie in $\mathbb{D}_W$, the wall κ_v is $\langle \mathbf{m}, v\rangle$, not identically 0 as $v \ne 0$ in V_W. So the composite is meromorphic on $\mathbb{D}_W$ with the stated poles, N_0 being arbitrary, and it agrees with the absolutely and locally uniformly convergent integral on $\mathcal{T}_g$, where it is holomorphic. The rest is the proof of Theorem 47.2(ii) with $\eta\,\mathbf{d}_1$, $\mathbf{d}_1$ a positive direction, in place of $\eta\,\mathbf{d}_\circ$: two writings of an insertion as combinations of the $\alpha^u \prod_i L_i^{-a_i}$ have one integral on the open set where all their integrals converge, which contains $\eta\,\mathbf{d}_1$ for large η, every wall $\kappa_v(\eta\,\mathbf{d}_1) + \kappa_v(g)$ being positive for large η; the value of an element of $\mathcal{L}_W$ vanishes on the intersection of the tubes of its insertions, open and containing $\eta\,\mathbf{d}_1$ for large η, off the poles of its coefficients, hence identically; and $\langle f_\lambda g\rangle$ and $\langle g\rangle(\cdot + \lambda)$ are one integral on the open set of the $\mathbf{d}$ at which $\mathbf{d} + \lambda$ lies in the tubes of the insertions of a writing of g, the insertions of the expansion of $f_\lambda g$ having tubes that contain those translated by $-\lambda$. At a real $\mathbf{d} \in \mathcal{T}_1$ the density is positive.

(iii) The proof of Theorem 47.4 applies, with these changes.

- In (i), $\partial_{y_e}(f_\lambda g) = f_\lambda(c_e(\lambda) + \partial_{y_e})g$ and the linearity of c_e give $(c_e(\mathbf{d}) + \partial_{y_e})(f_\lambda g) = f_\lambda(c_e(\mathbf{d} + \lambda) + \partial_{y_e})g$, and, written out, $(c_e(\mathbf{d}) + \partial_{y_e})g = g \otimes m_e - \sum_i R_{i,e} g \otimes w_i + \partial_{y_e} g \otimes 1$.
- In (ii), for $(u; \mathbf{a}) \in \mathbb{D}_W(\mathbb{Z})$ the vector $(u; \mathbf{a}) - \sum_i a_i(\mathbf{t}_i; \mathbf{e}_i) = (u - \sum_i a_i \mathbf{t}_i; \mathbf{0})$ has its first part in M_W, so the $(v; \mathbf{0})$, v in a basis of M_W, and the $(\mathbf{t}_i; \mathbf{e}_i)$ generate $\mathbb{D}_W(\mathbb{Z})$; for each of these $f_{-\mu}$ is a Laurent insertion, α^{-v} or $\alpha^{-\mathbf{t}_i} L_i = \sum_{\mathbf{t}} c_{i,\mathbf{t}} \alpha^{\mathbf{t}-\mathbf{t}_i}$.
- In (iii), let $\chi_1, \dots, \chi_{r_W}$ be a basis of M_W and $\beta_k = \alpha^{\chi_k}$, coordinates of the quotient torus, with the derivations δ_k, $\delta_k \beta^{\mathbf{n}} = n_k \beta^{\mathbf{n}}$, and the basis $d\beta_k/\beta_k$ of the 1-forms. On $\mathbb{C}[X_W]$, $\partial_{y_e} = \sum_k (\chi_k)_e\, \delta_k$, and the matrix $((\chi_k)_e)_{k,e}$ has rank r_W, so each δ_k is a rational combination of the ∂_{y_e}; let $c_{(k)}(\mathbf{d})$ be the same combination of the $c_e(\mathbf{d})$, so that $c_e = \sum_k (\chi_k)_e c_{(k)}$. The 1-form $c(\mathbf{d}) = \sum_k c_{(k)}(\mathbf{d})\, d\beta_k/\beta_k$ over $\mathbb{K}_W$ is $d\log(\omega_{\mathbf{d}}/dy)$, the coefficients being the derivatives of one logarithm, $c_{(k)} = \delta_k \log(\omega_{\mathbf{d}}/dy)$ on the orthant; so $\delta_l c_{(k)} = \delta_k c_{(l)}$, and $\nabla = d + c(\mathbf{d})\wedge$ is an integrable connection on the structure sheaf of X_W over $\mathbb{K}_W$. For the form $g\,(d\beta/\beta)_{\hat k}$ of degree $r_W - 1$, the product of the $d\beta_l/\beta_l$, $l \ne k$, ∇ gives $\pm(c_{(k)}(\mathbf{d}) + \delta_k)g$ times the top form, and these span $\mathcal{L}_W$, each $(c_e(\mathbf{d}) + \partial_{y_e})g$ being a combination of them and each of them

a combination of the $(c_e(\mathbf{d}) + \partial_{y_e})g$. So $\mathfrak{M}_W$ is the top cohomology, finite-dimensional as there.

- (iv) and (v) apply verbatim.

(iv) The proofs of Definition 47.6, Proposition 47.7 and Theorem 47.8 apply, with these changes.

- The coefficients $m_e + u_e$ and $w_i + a_i$ of $\mathrm{MR}_e(g)$ are affine on $\mathbb{D}_W$ and not constant, unless the mark e occurs in no letter, when $\mathbf{e}_e \in \vec{\mathcal{N}}_W^\perp$, m_e and u_e vanish on $\mathbb{D}_W$ and its lattice, and $\mathrm{MR}_e(g) = 0$; and $\mathrm{MR}_e(g)$ evaluates to $(c_e(\mathbf{d}) + \partial_{y_e})$ applied to the evaluation of g: ∂_{y_e} multiplies α^u by u_e and $L_i^{-w_i-a_i}$ by $-(w_i + a_i)R_{i,e}$, and $R_{i,e}\,\alpha^u \prod_l L_l^{-a_l} = \sum_{\mathbf{t}} c_{i,\mathbf{t}} t_e\, \alpha^{u+\mathbf{t}} \prod_l L_l^{-a_l-\delta_{il}}$.
- In Proposition 47.7(i), on each cone $|g|\, f^x_{\mathbf{d}_1} = \prod_k q_k^{\kappa_{v_{\pi,k}}(g)+x\kappa_{v_{\pi,k}}(\mathbf{d}_1)} \prod_i k_{i,\pi}^{-a_i-xw_{1,i}}$ (Lemma 48.2(iii)), bounded on the cube exactly when every exponent is nonnegative.
- In (ii) and (iii), the bound of Theorem 7.13 is replaced by $\langle \mathbf{t} - \mathbf{t}_i, v\rangle \geq \min_{\mathbf{t}'} \langle \mathbf{t}' - \mathbf{t}_i, v\rangle = -\kappa_v(\mathbf{t}_i; \mathbf{e}_i)$ for an exponent $\mathbf{t}$ of L_i: a monomial $\alpha^{u+\mathbf{t}-\mathbf{t}_i}$ of $f_{-\mu}\alpha^u$, $\mu = (\mathbf{t}_i; \mathbf{e}_i)$, has a wall at least $\kappa_v(\alpha^u) - \kappa_v(\mu)$, and $\alpha^{u-v'}$, for $\mu = (v'; \mathbf{0})$, has exactly that wall; and a term $(u+\mathbf{t}; \mathbf{a}+\mathbf{e}_i)$ of a mark relation or of a letter identity of g has the walls $\kappa_v(g) + \kappa_v(\mathbf{t}; \mathbf{e}_i) \geq \kappa_v(g)$. The generators of a fan span V_W positively, every point lying in a cone, so a nonzero $u \in M_W$ is negative at some generator, which gives the wall degree of a Laurent symbol positive off $u = 0$; and the set of the $x \in \vec{\mathcal{N}}_W$ with $\langle x, v\rangle \geq c_v$ at every generator is bounded, which gives finitely many symbols of bounded wall degree at each level.
- In (v), lifting every symbol by the letter identities to the top level $\bar{\mathbf{a}}$ and clearing the denominator $\prod_i L_i^{\bar{a}_i}$ leaves the independence of distinct Laurent monomials, as in the proof of Proposition 39.18(ii).
- The walls of symbols are integers (Lemma 48.2(ii)), which gives the discrete set of Theorem 47.8(iv).

(v) The supports of K_j and Ψ_j are the $\mathbf{1}_T$ and the $\mathbf{1}_{\mathcal{E}\setminus T}$, T a basis of table j, so $\vec{\mathcal{N}}_F^\perp$ is the set of the w with $\langle w, \mathbf{1}_T\rangle$ constant over the bases of every table. By Lemma 7.8 such a w is constant on every molecule; conversely the indicator of a molecule $\mathcal{E}_M$, a union of molecules of every table (Proposition 7.9), has $\langle \mathbf{1}_{\mathcal{E}_M}, \mathbf{1}_T\rangle = |T \cap \mathcal{E}_M|$ constant over the bases of every table (Lemma 7.10). So $\vec{\mathcal{N}}_F^\perp$ is spanned by the indicators of the molecules, and it is $\mathbb{R}\mathbf{1}$ exactly for one molecule. For one molecule the sectors of the orders form a fan with the generators $\mathbf{1}_U$ and the walls $\kappa_{\mathbf{1}_U} = \kappa_U$ (proof of Theorem 31.4(ii), the case of a piece of tables, with the tables of F at the exponents s_j, t_j), so the data space, the insertions (Definition 38.1), the relations, the walls, the tubes, the strides and the readings of a box are those of Chapter 47; the criterion of (i) is Theorem 25.2, and (ii)–(iv) are the statements cited. For a compound, $\mathbf{m} - \sum_j (s_j \mathbf{1}_{T_j} + t_j \mathbf{1}_{\mathcal{E}\setminus T'_j}) \in \vec{\mathcal{N}}_F \otimes \mathbb{C}$ says that it pairs to 0 with the indicator of every molecule, so every molecule is balanced. When the weights factor across the molecules the letters factor (Proposition 7.9), V_F is the sum of the spaces $\mathbb{R}^{\mathcal{E}_M}/\mathbb{R}\mathbf{1}$ of the molecules $\mathcal{E}_M$ with the sum of their lattices, the density is the product of the densities of the molecules, and the period read on V_F is the product of their periods. □

Definition 48.4 (A share reading). As stated.

Proof. The admissible cone is cut out of $\mathbb{S}(\mathbb{R})$ by the strict inequalities $\ell_k > 0$ and, for each node, $\kappa_v \circ \iota_l > 0$ at the generators of a fan of W_l (Lemma 48.2), all linear; so it is an open convex cone. At a real $\mathbf{d}$ the contour of Definition 4.1 through $\mathbf{c}$ is $\mathbf{c} + iV$, $\boldsymbol{\pi}(\mathbf{d})$ being real. □

Theorem 48.5 (The module along a share reading). *As stated.*

Proof. (i) $\Gamma(x+n) = (x)_n\Gamma(x)$ for every integer n, $(x)_n$ a polynomial for $n \geq 0$ and the inverse of one for $n < 0$, and every $\ell_k(\lambda,\tau)$ and $\ell'_k(\lambda,\tau)$ is an integer; the cocycle identity is $G(\cdot+\mu+\nu)/G = \big(G(\cdot+\mu+\nu)/G(\cdot+\mu)\big)\big(G(\cdot+\mu)/G\big)$.

(ii) ι_l is linear and onto, so a nonzero rational function on $\mathbb{D}_{W_l}$ read through ι_l is a nonzero rational function on $\mathbb{S}$, and ι_l^* is an embedding $\mathbb{K}_{W_l} \to \mathbb{K}_{\mathbb{S}}$; the base change of a space of dimension $\mathfrak{m}_{W_l}$ has that dimension over $\mathbb{K}_{\mathbb{S}}$, and the tensor product has the product of the dimensions, with the products of bases as a basis. ι_l being linear, $\sigma_{(\lambda,\tau)} \circ \iota_l^* = \iota_l^* \circ \sigma_{\iota_l(\lambda,\tau)}$, so $x \otimes \rho \mapsto \mathrm{Sh}_{\iota_l(\lambda,\tau)}\, x \otimes \sigma_{(\lambda,\tau)}\rho$ is well defined and $\sigma_{(\lambda,\tau)}$-semilinear on each factor, and so is the tensor product of these maps; multiplying by $R_{\lambda,\tau}$ keeps semilinearity, and the cocycle identity of (i) with $\mathrm{Sh}_\mu \mathrm{Sh}_\nu = \mathrm{Sh}_{\mu+\nu}$ on the nodes (Theorem 48.3(iii)) gives an action. On the basis, $\mathrm{Sh}_{(\lambda,\tau)} \bigotimes_l [g_{i_l}^{(l)}] = R_{\lambda,\tau} \bigotimes_l \sum_k \iota_l^* \mathbf{A}^{(l)}_{\iota_l(\lambda,\tau),i_l k} [g_k^{(l)}]$, whose matrix is the stated Kronecker product. The value of each factor is $\mathbb{K}_{W_l}$-linear with meromorphic values (Theorem 48.3(iii)), read through the linear surjection ι_l it is meromorphic on $\mathbb{S}$ and $\mathbb{K}_{\mathbb{S}}$-linear, and the product over the factors is multilinear, so it defines the value on $\mathfrak{J}$. For $t = \rho \bigotimes_l x_l$ the value of $\mathrm{Sh}_{(\lambda,\tau)}\, t$ at $(\mathbf{d},\mathbf{z})$ is $G(\mathbf{d},\mathbf{z})R_{\lambda,\tau}(\mathbf{d},\mathbf{z})\rho\big((\mathbf{d},\mathbf{z})+(\lambda,\tau)\big)\prod_l \langle x_l\rangle\big(\iota_l(\mathbf{d},\mathbf{z}) + \iota_l(\lambda,\tau)\big)$, by (i) and by the intertwining on the nodes, which is the value of t at $(\mathbf{d},\mathbf{z})+(\lambda,\tau)$.

(iii) $\langle \mathrm{Sh}_\lambda[1]\rangle(\mathbf{d}) = P_W(\mathbf{d}+\lambda)$ (Theorem 48.3(iii)). As $\mathbf{P}\tau = \boldsymbol{\pi}(\lambda)$, $\mathbf{c}+\tau$ is a real point of the pins at $\mathbf{d}+\lambda$, admissible by hypothesis, and the reading identity at $\mathbf{d}+\lambda$ through $\mathbf{c}+\tau$ gives $P_W(\mathbf{d}+\lambda)$ as the integral of $G\prod_l P_{W_l} \circ \iota_l$ over $\mathbf{c}+\tau+iV$. The substitution $\mathbf{z} \mapsto \mathbf{z}+\tau$ carries $\mathbf{c}+iV$ onto it and keeps the measure of Definition 4.1, $\boldsymbol{\pi}(\mathbf{d})$ and $\boldsymbol{\pi}(\mathbf{d}+\lambda)$ being real; the integrand becomes the value of $\mathrm{Sh}_{(\lambda,\tau)}[1]^\otimes$ at $(\mathbf{d},\mathbf{z})$, by (ii), the value of [1] at a node being its period. By Theorem 48.3(iii), $\mathrm{Sh}_\mu[1] = \boldsymbol{\rho}_\mu^{(l)} \cdot [\mathbf{g}^{(l)}]$, so the value of a factor is $\boldsymbol{\rho}_\mu^{(l)} \cdot \langle \mathbf{g}^{(l)}\rangle$ as a meromorphic function, and on the contour, where the value of $\mathrm{Sh}_{(\lambda,\tau)}[1]^\otimes$ is holomorphic, the integrand is the displayed one. For $x = \sum_\lambda r_\lambda \mathrm{Sh}_\lambda[1]$ the value at $\mathbf{d}$, off the poles of the r_λ, is $\sum_\lambda r_\lambda(\mathbf{d}) P_W(\mathbf{d}+\lambda)$, and the sum of the fibre integrals through one point is the fibre integral of the value of t_x, the coefficients r_λ, rational functions of $\mathbf{d}$ alone, being constant on the fibre. For the existence, let $\mathbf{c}_0$ be a real point of the pins at $\mathbf{d}$; $\mathbb{S}^+$ is an open cone containing $(\mathbf{d}_1,\mathbf{c}_1)$, so $(\mathbf{d},\mathbf{c}_0)+\eta(\mathbf{d}_1,\mathbf{c}_1)$ and the finitely many $(\mathbf{d}+\lambda,\mathbf{c}_0+\tau_\lambda)+\eta(\mathbf{d}_1,\mathbf{c}_1)$ lie in it for all large η, and $\mathbf{c}_0+\eta\mathbf{c}_1$ is the point asked at $\mathbf{d}+\eta\mathbf{d}_1$. $\mathbb{D}'_W(\mathbb{Z})$ is a subgroup, so every $\lambda \in \mathbb{D}_W(\mathbb{Z})$ is $\lambda_c + \lambda'$ with $\lambda' \in \mathbb{D}'_W(\mathbb{Z})$ and λ_c the representative of its class, and $\mathrm{Sh}_\lambda[1] = \mathrm{Sh}_{\lambda_c}\mathrm{Sh}_{\lambda'}[1]$; the shifts of [1] span $\mathfrak{M}_W$ (Theorem 48.3(iii)), and $\langle \mathrm{Sh}_{\lambda_c}\, x_c\rangle(\mathbf{d}) = \langle x_c\rangle(\mathbf{d}+\lambda_c)$.

(iv) The substitution $\mathbf{z} \mapsto \mathbf{z}+\tau$, τ real, carries the contour through $\mathbf{c}$ onto that through $\mathbf{c}+\tau$, with the same imaginary parts and measure, and turns the value of $[1]^\otimes$ into that of $\mathrm{Sh}_{(0,\tau)}[1]^\otimes$, by (ii); the reading identities through $\mathbf{c}$ and through $\mathbf{c}+\tau$ both give $P_W(\mathbf{d})$.

(v) The bijections carry the exponents, the data spaces, the lattices, the strides, the defects, the relations and the boxes of one family to those of the other, and the master forms and the values with them; so they carry the modules, with their shifts, masters, shift matrices and reductions. A box of each class gives its module (Theorem 48.3(iv)).

(vi) The shares $(\mathbf{z},\mathbf{z}')$ are pinned by $\mathbf{P}\mathbf{z} = \boldsymbol{\pi}(\mathbf{d})$ and $\mathbf{P}'\mathbf{z}' = \boldsymbol{\pi}'(\iota_{l_0}(\mathbf{d},\mathbf{z}))$, rows independent, the matrix being block triangular with the blocks $\mathbf{P}$ and $\mathbf{P}'$, ι_{l_0} extended linearly from $\mathbb{S}$. The forms of the kernel are integral on $\mathbb{S}''(\mathbb{Z})$, which $(\mathbf{d},\mathbf{z},\mathbf{z}') \mapsto (\iota_{l_0}(\mathbf{d},\mathbf{z}),\mathbf{z}')$ maps into the lattice of the inner share space, and every node map is linear and onto, ι_{l_0} and ι'_k being onto. At a point as stated, $(\mathrm{Re}\,\mathbf{d},\mathbf{c}) \in \mathbb{S}^+$, so the reading identity of W holds through $\mathbf{c}$. On its contour $\iota_{l_0}(\mathbf{d},\mathbf{z})$ has the real part $\iota_{l_0}(\mathrm{Re}\,\mathbf{d},\mathbf{c})$, at which $\mathbf{c}'$ is admissible, so the reading identity of W_{l_0} holds at every point of the contour through $\mathbf{c}'$, and a point admissible for the inner reading has its data in the

tube of W_{l_0}. Substituting, the iterated integral converges absolutely by hypothesis, so by Fubini's theorem it is the fibre integral over both pins, the normalizations of Definition 4.1 multiplying; its admissible cone is the set of the points stated. □

Definition 48.6 (The path of a basis). As stated.

Proof. For $1 \le l \le L-1$, $T \setminus S_l$ is the room side of T at the bunch S_l, its pattern being $T \cap S_l$, so it lies in one station. $T \setminus S_{l-1} = (T \cap B_{l-1}) \sqcup (T \setminus S_l)$, so with $X = T \setminus S_l \in D_l(T)$ and $q = T \cap B_{l-1}$, $q \sqcup X$ is a room side of S_{l-1} in $D_{l-1}(T)$, and α^q, with the coefficient $w'_{T\setminus S_{l-1}}/w'_{T\setminus S_l}$, is a term of $\mathbf{N}^K_{l,j}(D_{l-1}(T), D_l(T))$, and $\alpha^{B_{l-1}\setminus q}$ of $\mathbf{N}^\Psi_{l,j}$, the coefficients not depending on the member X (Theorem 29.2(i)). The room child of $D_1(T)$ is the table on S_1 with the bases p such that $p \sqcup X \in \mathcal{B}_j$ for $X \in D_1(T)$ (Definition 28.1(ii)), among them $T \cap S_1$ with $X = T \setminus S_1$, whose term in $K_{j,(D_1(T))}$ is $\theta_{j,(D_1(T)),T\cap S_1}\alpha^{T\cap S_1}$ and in $\Psi_{j,(D_1(T))}$ the same coefficient times $\alpha^{S_1\setminus T}$. $T \cap B_{L-1} = T \setminus S_{L-1}$ is a room side in $D_{L-1}(T)$, a term of $\mathsf{y}_{j,D_{L-1}(T)}$ with the coefficient $w'_{T\setminus S_{L-1}}$, and $\alpha^{B_{L-1}\setminus T}$ one of $\mathsf{y}^*_{j,D_{L-1}(T)}$. □

Theorem 48.7 (A chain of bunches is a share reading). *As stated.*

Proof. In the proof the pins at every node, its *pins of directions*, are $\iota_l(\mathbf{d}, \mathbf{z}) \in \mathbb{D}_{W_l}$; the degree of the entry (D', D) of K_j at the node l is $|D'| - |D|$, $|D|$ the common size of the room sides in the station D, and that of the seam letter of S_1 at D is $r_j - |D|$, as at the path of any basis (proof of Definition 48.6); for Ψ_j, with $\bar{c}(D) = |\mathcal{E} \setminus S_l| - |D|$ at a station D of S_l, they are $\bar{c}(D') - \bar{c}(D)$, $r^*_j - \bar{c}(D)$ at the first bunch, and $\bar{c}(D)$ at the last node.

(i) *The share space.* The pins are linear with integral coefficients in the shares and the data: the letter totals $\sum_D a^{(1)}_{jD} = s_j$ and $\sum_D b^{(1)}_{jD} = t_j$, where $a^{(1)}_{jD} = \sum_{D''} e^{(2)}_{jDD''}$; the conservation $\sum_{D'} e^{(l)}_{jD'D} = \sum_{D''} e^{(l+1)}_{jDD''}$ at the stations D of S_l, $2 \le l \le L-1$, and alike with f; and the pins of directions of the nodes, taken on bases of the lattices $\vec{\mathcal{N}}^\perp_{W_l} \cap \mathbb{Z}^{B_{l-1}}$ that contain $\mathbf{1}_{B_{l-1}}$, whose pins are the homogeneities. They have one dependence: the sum of the homogeneities is $\sum_j (r_j$ times the letter total of K_j and r^*_j times that of $\Psi_j)$ plus, at every station D of S_l, $2 \le l \le L-1$, the conservation pin of K_j times $|D|$ and that of Ψ_j times $|\mathcal{E} \setminus S_l| - |D|$, each written as the out-load less the in-load, by the balance computation below, with the coefficient 1 on every homogeneity. There is no other. The letter totals and the conservation are the equations of a flow on a connected network at every vertex but the sink, so they are independent. If a combination of the pins of directions, with vectors $\mathbf{v}_l \in \vec{\mathcal{N}}^\perp_{W_l}$, is a combination of them, its value at the shares of a path vector τ_T is $\langle \mathbf{1}_T, w\rangle$, $w = \sum_l \mathbf{v}_l$, and equals the coefficient of the letter total of K_j; so $\langle w, \mathbf{1}_T\rangle$ and, likewise, $\langle w, \mathbf{1}_{\mathcal{E}\setminus T}\rangle$ are constant over the bases of every table, w is constant (Lemma 7.8, F being one molecule), and every $\mathbf{v}_l$ is the same multiple of $\mathbf{1}_{B_{l-1}}$. $\mathbf{P}$ is the set of all of them but the homogeneity of one node, and $\boldsymbol{\pi}$ their right-hand sides: these are the pins of Corollary 29.5, the letter totals, the conservation, and the homogeneity of the first bunch and of every node but one, with the pins of Theorem 28.12 at a bunch or a node whose Newton sum is degenerate, the lattice bases there completing the indicators of the steps. Leaving out the homogeneity of another node, or taking other such bases, changes $\mathbf{P}$ by a unimodular matrix and leaves the fibre integral of Definition 4.1 unchanged; leaving out a letter total or a conservation pin instead would divide it by the absolute value of the coefficient of that pin in the dependence, the remaining pins being dependent when it is 0.

The balance. On the pins the total degree of the shares of K_j at all the nodes is $\sum_D a^{(1)}_{jD}(r_j - |D|) + \sum_{l=2}^{L-1}\sum_{D',D} e^{(l)}_{jD'D}(|D'| - |D|) + \sum_D e^{(L)}_{jD}|D|$, which telescopes by the conservation to $s_j r_j$;

likewise, with $\bar{c}$ in place of $|D|$, to $t_j r_j^*$ for Ψ_j. With the homogeneity of the nodes, $m_{\mathcal{E}} = \sum_j (s_j r_j + t_j r_j^*)$: the data of a point of the pins lie on the balance wall.

The maps are onto. Every station D of S_l, $1 \le l \le L-1$, has a nonzero entry of the node $l+1$ out of it and, for $l \ge 2$, one of the node l into it: for $X = T \setminus S_l \in D$, the entries $(D_{l-1}(T), D)$ and $(D, D_{l+1}(T))$ of the path of T are nonzero, the last node having the entry D. Given data $(\mathbf{m}'; \mathbf{e}', \mathbf{f}')$ of the node l, the loads they put on the stations at both ends of the node are carried station by station by shares of the neighbouring nodes, down to the first bunch, whose shares are its loads, and up to the last node, whose shares are the loads at S_{L-1}; the letter totals then give s_j and t_j, masses on the other steps satisfying their pins of directions exist, $\mathbf{m} - \sum_i w_i \mathbf{t}_i$ ranging over $\vec{\mathcal{N}} \otimes \mathbb{C}$, and the data lie on the balance wall. So ι_l is onto, and likewise ι_1. At real data with positive exponents and masses on the balance wall with every proper wall positive, F has a native gauge (Theorem 8.19(iii)), and the native split at the stations and the entries (Lemmas 28.9 and 29.4) is a point of the pins with positive shares at which the masses of every node lie in the relative interior of its Newton sum, so in its space of directions and, by Theorem 48.3(i), in its tube. These data form a nonempty open set of real points of $\mathbb{D}_F$, the centre data among them, so every $\mathbf{d}$ has shares on its pins, the pins being linear, and $\mathbb{S}^+$ is not empty. The forms of the kernel, shares, loads and the coordinates s_j, t_j, are integral on $\mathbb{S}(\mathbb{Z})$, and the ι_l are coordinate maps, integral on it.

Absolute convergence. At a real $\mathbf{d}$ and an admissible $\mathbf{c}$, on the contour $\mathbf{c}+i\mathbf{y}$, $\mathbf{y} \in V$, every node has $|P_{W_l}(\iota_l(\mathbf{d}, \mathbf{c}+i\mathbf{y}))| \le P_{W_l}(\iota_l(\mathbf{d}, \mathbf{c}))$, so it suffices that $\int_V |G(\mathbf{d}, \mathbf{c}+i\mathbf{y})|\, d\mathbf{y} < \infty$. By Stirling's formula, uniformly for real parts in a compact subset of $(0, \infty)$, $|\Gamma(x+iu)|$ and $1/|\Gamma(x+iu)|$ are at most a constant times $(1+|u|)^{x-1/2} e^{-\pi|u|/2}$ and $(1+|u|)^{1/2-x} e^{\pi|u|/2}$, so $|G| \le C_0 (1+|\mathbf{y}|)^n e^{-\frac{\pi}{2} E(\mathbf{y})}$ with

$$E(\mathbf{y}) = \sum_{l=2}^{L-1} \Big(\sum_{D', D} |y_{D'D}^{(l)}| - \sum_D |A_D^{(l)}| \Big) + \sum_D |A_D^{(L-1)}|$$

for each letter, summed over the letters, $y_{D'D}^{(l)}$ the imaginary parts of its shares and $A_D^{(l)}$ that of the load at the station D of S_l, $\sum_{D'} y_{D'D}^{(l)}$ for $l \ge 2$ and $\sum_{D''} y_{DD''}^{(2)}$ for $l = 1$, the letter totals s_j, t_j being real and the last node's shares being the loads at S_{L-1}. Every bracket is nonnegative. If $E(\mathbf{y}) = 0$ the loads at S_{L-1} vanish, then so do the shares of the node $L-1$, the bracket at $L-1$ being 0, then the loads at S_{L-2}, which are their sums out of each station, and so on down to the node 2: $\mathbf{y} = 0$. E is continuous and positively homogeneous of degree one, so $E(\mathbf{y}) \ge \varepsilon |\mathbf{y}|$ on V for some $\varepsilon > 0$, and the integral converges; the bounds are uniform for the real parts in a compact set and for imaginary translates of the contour by a bounded amount, $E(\mathbf{y}+\mathbf{y}_0) \ge E(\mathbf{y}) - C_1 |\mathbf{y}_0|$.

The identity. At a real $\mathbf{d}$ with an admissible $\mathbf{c}$ the shares are positive, so $s_j, t_j > 0$, every bunch S_l, $0 < l < L$, has a table of positive width, F being one molecule (Lemma 7.10), and the nodes converge at their data, which lie in their tubes; so the contour is one of Corollary 29.5, which gives $P_F(\mathbf{d})$ as the fibre integral, the period being by Theorem 29.3(ii) an integral of positive functions against the laws. The fibre integral converges, so $P_F(\mathbf{d})$ is finite, every proper wall is positive (Theorem 8.7), and $\mathbf{d} \in \mathcal{T}_1(F)$. For complex data let U be the set of the $\mathbf{d}$ at which some point is admissible, the tube over the projection of $\mathbb{S}^+$, connected. Near $\mathbf{d}_0 \in U$, with $\mathbf{c}_0$ admissible at $\mathbf{d}_0$, a rational $\mathbf{Q}$ with $\mathbf{PQ} = 1$ and $\mathbf{y}_0$ with $\mathbf{P}\mathbf{y}_0 = \boldsymbol{\pi}(\operatorname{Im} \mathbf{d}_0)$, the contour $\mathbf{z} = \mathbf{Q}\boldsymbol{\pi}(\mathbf{d} - \mathbf{d}_0) + \mathbf{c}_0 + i(\mathbf{y}_0 + \mathbf{y})$, $\mathbf{y} \in V$, lies on the pins at $\mathbf{d}$ through a point admissible at $\mathbf{d}$, and by the bounds the fibre integral is holomorphic in $\mathbf{d}$ near $\mathbf{d}_0$; by Cauchy's theorem it does not depend on the admissible point, the admissible points at $\mathbf{d}$ forming a convex set. So both sides are holomorphic on U, which lies in $\mathcal{T}_1(F)$, its real points doing so and $\mathcal{T}_1(F)$ being a tube; they agree at its real points, a nonempty open subset of $\mathbb{D}_F(\mathbb{R})$, so they agree on U.

(ii) λ^K_T lies on the balance wall, $|T| = r_j$, and is integral. τ_T adds 1 to one entry of each node $2,\dots,L$ along the path, so it adds 1 to the load $a^{(1)}_{jD_1(T)}$, to the letter total of K_j, which λ^K_T also raises by one, and to the in- and the out-load of every station $D_l(T)$, $2 \le l \le L-1$, keeping the conservation. At the node l the data move by $(\mathbf{1}_{T\cap B_{l-1}}; \mathbf{e})$, $\mathbf{e}$ the unit vector of the entry of the path, and $\mathbf{1}_{T\cap B_{l-1}}$ is an exponent of that entry (proof of Definition 48.6), so the move is the data of the stride of the piece of T in its entry, and it keeps the pins of directions, the difference of two exponents of one letter lying in its space of directions; at the first bunch the data move by $(\mathbf{1}_{T\cap S_1}; \mathbf{e})$, $\mathbf{e}$ the unit vector of $a^{(1)}_{jD_1(T)}$, likewise. So $(\lambda^K_T, \tau_T) \in \mathbb{S}(\mathbb{Z})$. The kernel gains the factor $e^{(l)}_{jD_{l-1}(T)D_l(T)}$ for every entry of the path, $l = 2,\dots,L$, the last being $e^{(L)}_{jD_{L-1}(T)} = a^{(L-1)}_{jD_{L-1}(T)}$ by the conservation, and loses s_j and $a^{(l)}_{jD_l(T)}$, $2 \le l \le L-1$ (Theorem 48.5(i)); cancelling $a^{(L-1)}$ and writing $e^{(2)}_{jD_1D_2}/s_j = (a^{(1)}_{jD_1}/s_j)(e^{(2)}_{jD_1D_2}/a^{(1)}_{jD_1})$ gives the product stated. Its factors are the probabilities of the chain stated, $\sum_D a^{(1)}_{jD} = s_j$ and $\sum_D e^{(l)}_{jD'D} = a^{(l-1)}_{jD'}$, the shares out of D' summing to its load. The cobasis is the same with f, b, t_j and the monomials $\alpha^{B_{l-1}\setminus T}$. The coefficients of the pieces in their entries are $\theta_{j,(D_1(T)),T\cap S_1}$, the ratios $w'_{T\setminus S_{l-1}}/w'_{T\setminus S_l}$ for $2 \le l \le L-1$, and $w'_{T\setminus S_{L-1}}$; their product telescopes to $\theta_{j,(D_1(T)),T\cap S_1}\, w'_{T\setminus S_1} = \theta_{j,T}$, the room child at $T \setminus S_1$ being $w'_{T\setminus S_1}$ times that of its station (Definition 28.1(ii)). So $\theta_{j,T}P_F(\mathbf{d}+\lambda^K_T)$, the value of the chance, is by Theorem 48.5(iii) the fibre integral of $G\,R_{\lambda^K_T,\tau_T}$ times the product over the nodes of the coefficient of the piece times the period at the moved data, the value of $\mathbb{P}^{(l)}(T)$.

(iii) Let $\lambda = (v; \mathbf{a}, \mathbf{b}) \in \mathbb{D}_F(\mathbb{Z})$, and fix bases T_j, T'_j of every table. Then $\lambda - \sum_j a_j\lambda^K_{T_j} - \sum_j b_j\lambda^\Psi_{T'_j} = (w; \mathbf{0}, \mathbf{0})$ with $w_{\mathcal{E}} = 0$, by the balance. Two marks e, e' linked by a circuit C of table j have a basis $T \supseteq C \setminus \{e\}$ avoiding e, and $T' = T \setminus \{e'\} \cup \{e\}$ is a basis, the circuit of e in $T \cup \{e\}$ being C; so $(\mathbf{e}_e - \mathbf{e}_{e'}; \mathbf{0}, \mathbf{0}) = \lambda^K_{T'} - \lambda^K_T$. The marks of F form one molecule, so any two are joined by a chain of linked pairs, and these differences span $\{w \in \mathbb{Z}^{\mathcal{E}} :\ w_{\mathcal{E}} = 0\}$. Every lattice vector is thus an integral combination of the λ^K_T and λ^Ψ_T, the image of the same combination of the (λ^K_T, τ_T) and $(\lambda^\Psi_T, \tau^*_T)$ by (ii). So $\mathbb{D}'_F(\mathbb{Z}) = \mathbb{D}_F(\mathbb{Z})$ and $\mathfrak{M}'_F = \mathfrak{M}_F$, the shifts of [1] spanning $\mathfrak{M}_F$ (Theorem 47.4(ii)), and Theorem 48.5(iii) applies to every element.

(iv) If the node $S^{(\mathbf{x})}_l$ is carried to $S^{(\mathbf{x}')}_{l'}$ by a bijection of marks keeping the seam letters, the stations of S_{l-1} and S_l corresponding to those of $S_{l'-1}$ and $S_{l'}$, the coefficient of $x_{D'}\alpha^{i(D')}_g$ in the seam letter at D, which is $\mathbf{N}^K_l(D', D)$, is carried to the coefficient of the corresponding term, $\mathbf{N}^K_{l'}$ at the corresponding entry, and likewise for Ψ; so the bijection of B_{l-1} onto $B_{l'-1}$ and that of the entries are an isomorphism of W_l onto $W_{l'}$, and Theorem 48.5(v) applies.

(v) The occupation is the sum of the chances of the bases through e, $R_{j,e} = \sum_{T\ni e}\theta_{j,T}\alpha^T/K_j$ (Definition 38.1), so $\langle R_{j,e}\rangle(\mathbf{d}) = \sum_{T\ni e}\theta_{j,T}P_F(\mathbf{d}+\lambda^K_T)$. By (ii) at a real $\mathbf{d}$, and at a complex one by the same substitution $\mathbf{z} \mapsto \mathbf{z} + \tau_T$, which keeps the imaginary parts of the contour (proof of Theorem 48.5(iv)), each term is, through a point as stated, with $\boldsymbol{\nu}_{l'} = \iota_{l'}(\mathbf{d}, \mathbf{z})$,

$$\theta_{j,T}P_F(\mathbf{d}+\lambda^K_T) = \int_{\text{pins}} G\,R_{\lambda^K_T,\tau_T}\prod_{l'}\theta^{(l')}(T)\,P_{W_{l'}}\big(\boldsymbol{\nu}_{l'} + \iota_{l'}(\lambda^K_T, \tau_T)\big),$$

$\theta^{(l')}(T)$ the coefficient of the piece of T in its entry at the node l'. A basis is determined by its path and its pieces. Conversely a path of stations with a nonzero entry at every node, with a term chosen in each entry, gives a basis: from the last node down, the pieces make room sides in the stations of the path, the coefficients and the stations of an entry not depending on the member of its station (Theorem 29.2(i)), and the term of the seam letter at the first station completes a

basis (Definition 28.1(ii)). This is the expansion of K_j as the product of the transfer matrices (Theorem 29.3(i)). Sum first over the pieces at a node $l' \neq l$, its entry E fixed. The entry is $N_E = \sum_q \theta_q \alpha^q$, so $\sum_q \theta_q \alpha^q / N_E = 1$, and the values give $\sum_q \theta_q P_{W_{l'}}(\boldsymbol{\nu}_{l'} + (\mathbf{1}_q; \mathbf{e}_E)) = P_{W_{l'}}(\boldsymbol{\nu}_{l'})$ (Theorem 48.3(ii)), whatever E. At the node l the pieces $q \ni e$ give $\sum_{q \ni e} \theta_q P_{W_l}(\boldsymbol{\nu}_l + (\mathbf{1}_q; \mathbf{e}_E)) = \langle R^{(l)}_{E,e} \rangle(\boldsymbol{\nu}_l)$, since $R^{(l)}_{E,e} = \alpha_e \partial_{\alpha_e} N_E / N_E = \sum_{q \ni e} \theta_q \alpha^q / N_E$. What is left is the sum of $R_{\lambda^K_T, \tau_T}$ over the paths through $E = (D', D)$, which is the probability that the chain of stations of (ii) passes through E. The probability of being at a station D'' of S_m is $a^{(m)}_{jD''}/s_j$, by induction on m, the shares into a station summing to its load, and the continuations have the total probability 1, the shares out of a station summing to its load. So the sum is $(a^{(l-1)}_{jD'}/s_j)(z_E/a^{(l-1)}_{jD'}) = z_E/s_j$; at the first bunch it is $a^{(1)}_{jD}/s_j$, and at the last node $a^{(L-1)}_{jD'}/s_j = z_E/s_j$. These are identities of rational functions on $\mathbb{S}$, and the sums are finite, so they pass through the integral, which gives the display. For Ψ_j the same holds with the cobasis chances and t_j. With the masses, which are coordinates of $\mathbf{d}$ and constant on the fibre, $\langle c_e(\mathbf{d}) \rangle(\mathbf{d}) = m_e P_F(\mathbf{d}) - \sum_j \big(s_j \langle R_{j,e} \rangle + t_j \langle R^*_{j,e} \rangle \big)(\mathbf{d})$ is, through a point as in the statement, the fibre integral of $G \, \langle c^{(l)}_e \rangle(\boldsymbol{\nu}_l) \prod_{l' \neq l} P_{W_{l'}}(\boldsymbol{\nu}_{l'})$, $c^{(l)}_e$ the defect of the node l at its data, whose exponents are the shares (Definition 48.1(iv)); both vanish, by Theorem 48.3(ii) for F and for the node. □

Lemma 48.8 (Exponential periods: their domains and their modules). *As stated.*

Proof. (i) Write $\alpha = e^y$, so that $\alpha^{\mathbf{m}-\mathbf{1}} d\alpha = e^{\langle \mathbf{m}, y \rangle} dy$. For a polynomial $h = \sum_{\mathbf{t}} a_{\mathbf{t}} \alpha^{\mathbf{t}}$ with nonnegative coefficients, N_h of them positive, $\max_{\mathbf{t}} a_{\mathbf{t}} e^{\langle \mathbf{t}, y \rangle} \leq h(e^y) \leq N_h \max_{\mathbf{t}} a_{\mathbf{t}} e^{\langle \mathbf{t}, y \rangle}$, the maxima over the exponents with $a_{\mathbf{t}} > 0$, so $|\log h(e^y) - \mathrm{top}_h(y)| \leq C_h$ with $C_h = \log N_h + \max_{\mathbf{t}} |\log a_{\mathbf{t}}|$. Hence there are constants C, C', the first uniform for $\mathrm{Re}\, \boldsymbol{\nu}$ in a bounded set, with

$$e^{\varphi_{\boldsymbol{\nu}}(y) - C} \leq \Big| e^{\langle \mathbf{m}, y \rangle} \prod_k h_k(e^y)^{-c_k} \Big| \leq e^{\varphi_{\boldsymbol{\nu}}(y) + C}, \qquad e^{\rho_i(y) - C'} \leq R_i(e^y) \leq e^{\rho_i(y) + C'}.$$

The functions $\varphi_{\boldsymbol{\nu}}$ and ρ_i are piecewise linear and positively homogeneous of degree one, so Lipschitz, with a constant Λ; $\varphi_{\boldsymbol{\nu}}$ is linear in $\mathrm{Re}\, \boldsymbol{\nu}$. Let Θ be the unit sphere of $\mathbb{R}^B$ and $K = C_0 \cap \Theta$, compact. Suppose $\varphi_{\boldsymbol{\nu}} < 0$ on K. Then $\varphi_{\boldsymbol{\nu}} \leq -2\varepsilon$ on K for some $\varepsilon > 0$, and $\varphi_{\boldsymbol{\nu}} \leq -\varepsilon$ on an open neighbourhood N of K in Θ; on the compact set $\Theta \setminus N$, which misses C_0, $\max_i \rho_i \geq \delta$ for some $\delta > 0$. In polar coordinates $y = rw$, $w \in \Theta$, the integrand is at most $e^{C - \varepsilon r}$ for $w \in N$ and at most $\exp\big(C + \Lambda r - \xi_{\min} e^{\delta r - C'}\big)$ for $w \notin N$, $\xi_{\min}$ the least scale, and both are integrable against $r^{|B|-1} dr\, dw$. For $\mathrm{Re}\, \boldsymbol{\nu}$ in a compact set on which $\varphi_{\boldsymbol{\nu}} < 0$ on K the maximum of $\varphi_{\boldsymbol{\nu}}$ on K is at most -2ε uniformly, $\varphi_{\boldsymbol{\nu}}$ depending continuously on $\boldsymbol{\nu}$, and N, δ and Λ can be taken uniformly; with the scales in a compact subset of $(0, \infty)^p$ the bounds are uniform, which is the local uniformity. Conversely let $w_0 \in K$ with $\varphi_{\boldsymbol{\nu}}(w_0) \geq 0$. On the half-cylinder $\{t w_0 + y' : \ t \geq 0, \ |y'| \leq 1\}$, $\rho_i(t w_0 + y') \leq t \rho_i(w_0) + \Lambda \leq \Lambda$ and $\varphi_{\boldsymbol{\nu}}(t w_0 + y') \geq -\Lambda$, so the integrand is at least $e^{-\Lambda - C} \exp\big(- \sum_i \xi_i e^{\Lambda + C'} \big) > 0$ there, and the half-cylinder has infinite volume: the integral diverges at every $\boldsymbol{\xi}$. The condition does not involve the scales; it is linear in $\mathrm{Re}\, \boldsymbol{\nu}$ at each $w \in K$, and strict on the compact K, so the set of the real parts it allows is an open convex cone. The last statement is the definition of the data, $\alpha^{\mathbf{u}} \prod_k h_k^{-n_k}$ moving $\mathbf{m}$ by $\mathbf{u}$ and $\mathbf{c}$ by $\mathbf{n}$.

(ii) Write $dy = \bigwedge_e dy_e$ and $\Omega_{\boldsymbol{\nu}} = \alpha^{\mathbf{m}} \prod_k h_k^{-c_k} \exp(-\sum_i \xi_i R_i)$, so that $\langle g \rangle_{\boldsymbol{\nu}} = \int_{\mathbb{R}^B} g \, \Omega_{\boldsymbol{\nu}} \, dy$. Let $\mathbb{K} = \mathbb{C}(\boldsymbol{\xi}, \boldsymbol{\nu})$, the scales and the data taken as indeterminates. On the smooth affine variety Y over $\mathbb{K}$ the 1-form $\omega = \sum_e m_e \, dy_e - \sum_k c_k \, d \log h_k - \sum_i \xi_i \, dR_i$ is closed, so $\nabla = d + \omega \wedge$ is an integrable connection on its structure sheaf, and the top cohomology H of its algebraic de Rham complex is finite-dimensional over $\mathbb{K}$, the fact used in Theorem 38.31(i) and in the proof of Theorem 47.4(iii).

On top forms put $D_i(g\,dy) = (\partial_{\xi_i} g - R_i g)\,dy$; since $\partial_{\xi_i}\omega = -dR_i$, $D_i\nabla\eta = \nabla D_i\eta$ for every form η of degree $|B|-1$, with D_i acting on its coefficients in the same way, so the D_i act on H, and they commute. Let $N \subseteq H$ be the span of the classes of the $D^{\mathbf{a}}(dy) = (-1)^{|\mathbf{a}|}\prod_i R_i^{a_i}\,dy$, of dimension $r \le \dim H$.

Take $\mathbf{a}_0, \dots, \mathbf{a}_r \in \mathbb{N}^p$. Their classes are dependent, so, clearing denominators, there are polynomials $c_0, \dots, c_r \in \mathbb{C}[\boldsymbol{\xi}, \boldsymbol{\nu}]$, not all zero, and a form $\eta = \sum_e \pm g_e\,dy_{\hat{e}}$ of degree $|B|-1$, $dy_{\hat{e}}$ the product of the $dy_{e'}$, $e' \ne e$, with coefficients $g_e \in \mathbb{C}[\boldsymbol{\xi}, \boldsymbol{\nu}] \otimes \mathbb{C}[Y]$, such that $\sum_k c_k \prod_i R_i^{a_{k,i}}\,dy = \nabla\eta = \sum_e (\partial_{y_e} + \omega_e) g_e\,dy$, $\omega_e = m_e - \sum_k c_k \partial_{y_e} \log h_k - \sum_i \xi_i \partial_{y_e} R_i$. Expanding the g_e in monomials of $(\boldsymbol{\xi}, \boldsymbol{\nu})$ gives finitely many elements of $\mathbb{C}[Y]$; let Φ consist of them, of their derivatives ∂_{y_e} and of their products with the $\partial_{y_e} \log h_k$ and the $\partial_{y_e} R_i$, all in $\mathbb{C}[Y] = \mathbb{C}[\alpha^{\pm 1}][(h_1 \cdots h_q)^{-1}]$. Each element of Φ is a finite combination of the $\alpha^{\mathbf{u}} \prod_k h_k^{-n_k}$, and by (i) $\langle g \rangle_{\boldsymbol{\nu}}$ converges absolutely for every $g \in \Phi$ and every $\boldsymbol{\xi}$ once $\boldsymbol{\nu} + (\mathbf{u}, \mathbf{n}) \in \mathcal{D}$ for the finitely many $(\mathbf{u}, \mathbf{n})$ that occur: for a given $\boldsymbol{\nu}_0 \in \mathcal{D}$ this holds on a neighbourhood of $\eta\boldsymbol{\nu}_0$ for all large η, the real parts of $\mathcal{D}$ forming an open cone. There both $g_e \Omega_{\boldsymbol{\nu}}$ and $\partial_{y_e}(g_e \Omega_{\boldsymbol{\nu}}) = \big((\partial_{y_e} + \omega_e) g_e\big)\Omega_{\boldsymbol{\nu}}$ are integrable over $\mathbb{R}^B$. An integrable function of one variable with an integrable derivative tends to 0 at both ends, so by Fubini's theorem $\int_{\mathbb{R}^B} \partial_{y_e}(g_e \Omega_{\boldsymbol{\nu}})\,dy = 0$, and

$$\sum_{k=0}^{r} c_k(\boldsymbol{\xi}, \boldsymbol{\nu}) \big\langle \textstyle\prod_i R_i^{a_{k,i}} \big\rangle_{\boldsymbol{\nu}}(\boldsymbol{\xi}) = 0$$

there. The left side is holomorphic in $\boldsymbol{\nu}$ on $\mathcal{D}$, the convergence being locally uniform by (i), and $\mathcal{D}$ is connected, so the relation holds on $\mathcal{D}$.

Fix $\boldsymbol{\nu}_0 \in \mathcal{D}$ and a direction $\mathbf{v}$ such that the polynomials $c_k(\boldsymbol{\xi}, \boldsymbol{\nu}_0 + \varepsilon\mathbf{v})$ in $(\boldsymbol{\xi}, \varepsilon)$ are not all zero; generic directions do. Let b be the least order of vanishing in ε among them, and write $c_k(\boldsymbol{\xi}, \boldsymbol{\nu}_0 + \varepsilon\mathbf{v}) = \varepsilon^b\big(c_k^0(\boldsymbol{\xi}) + \varepsilon\,\tilde{c}_k(\boldsymbol{\xi}, \varepsilon)\big)$ with polynomials c_k^0, not all zero. Dividing the relation at $\boldsymbol{\nu}_0 + \varepsilon\mathbf{v}$, which lies in $\mathcal{D}$ for small ε, by ε^b and letting $\varepsilon \to 0$, the values being continuous in $\boldsymbol{\nu}$, gives $\sum_k c_k^0(\boldsymbol{\xi}) \langle \prod_i R_i^{a_{k,i}} \rangle_{\boldsymbol{\nu}_0} = 0$. So any $r+1$ of the functions $\langle \prod_i R_i^{a_i} \rangle_{\boldsymbol{\nu}_0}$ are dependent over $\mathbb{C}(\boldsymbol{\xi})$, and their span has dimension at most r. Differentiation under the integral, justified by the locally uniform convergence, gives $\partial_{\xi_i} \langle g \rangle_{\boldsymbol{\nu}} = \langle -R_i g \rangle_{\boldsymbol{\nu}}$ for g a monomial in the R's, so the span is that of the derivatives of $\langle 1 \rangle_{\boldsymbol{\nu}_0}$ and is closed under the ∂_{ξ_i}.

(iii) Let the subtorus be the image under $y \mapsto e^y$ of a rational subspace $V_T \subseteq \mathbb{R}^B$, and choose a basis $\mathbf{b}_1, \dots, \mathbf{b}_{|B|}$ of $\mathbb{Z}^B$ whose first r vectors are a basis of $V_T \cap \mathbb{Z}^B$, a saturated sublattice. In the coordinates β with $\log \alpha = \sum_j (\log \beta_j)\,\mathbf{b}_j$, a change of variables of determinant ± 1 with $d\alpha/\alpha = d\beta/\beta$, the integrand does not depend on $\beta_1, \dots, \beta_r$, and the integral over the quotient is the integral over $\beta' = (\beta_{r+1}, \dots, \beta_B)$ at $\beta_1 = \cdots = \beta_r = 1$. There $\alpha^{\mathbf{t}}$ is $\beta'^{(\langle \mathbf{t}, \mathbf{b}_j \rangle)_{j>r}}$, so a polynomial with nonnegative coefficients becomes $\beta'^{\mathbf{s}} h'$, h' a polynomial in β' with nonnegative coefficients and $\mathbf{s}$ the least exponents, and the integrand is of the kind of the lemma on the marks $r+1, \dots, |B|$, with the polynomials h_k', the functions $R_i' = \beta'^{\mathbf{w}_i'} P_i' \prod_k h_k'^{-n_{ik}}$, and the data $(\mathbf{m}', \mathbf{c})$, $\mathbf{m}'$ linear in $(\mathbf{m}, \mathbf{c})$. □

Definition 48.9 (The group at several scales; the inputs and the group of a word). As stated.

Proof. (i) The connections commute, so near a point off the singular locus the horizontal sections form a space of the dimension of N (the Frobenius theorem for integrable connections), and the field they generate over $\mathbb{C}(\mathbf{y})$ with their derivatives is a Picard–Vessiot extension for the commuting derivations ∂_{y_e}, the field of constants $\mathbb{C}$ being algebraically closed; its group of differential automorphisms over $\mathbb{C}(\mathbf{y})$ is a linear algebraic group acting faithfully on $\mathrm{Sol}_x N$, with the Galois correspondence (Picard–Vessiot theory for several commuting derivations, Kolchin's). When N

is regular singular along its singular locus, the regular singular connections on the complement and its local systems are equivalent categories with their tensor structures (the Riemann–Hilbert correspondence for regular singular connections), and the group is the Zariski closure of the monodromy. Continuation along a path conjugates the group at x to that at another point, as in the proof of Definition 45.24. The derivatives of a function span, over $\mathbb{C}(\mathbf{y})$, a space closed under the ∂_{y_e}, since $\partial_{y_e}(r\,\partial^{\mathbf{a}} f) = (\partial_{y_e} r)\,\partial^{\mathbf{a}} f + r\,\partial^{\mathbf{a}+\mathbf{e}_e} f$; with $\nabla_e = \partial_{y_e}$ it is a differential module when it is finite-dimensional.

(ii) The inputs and the group are defined by (i). At one scale every density is a function on $(0,\infty)$ and the sum is over $\mathbb{C}(y)$, which is Definition 45.32. □

Proposition 48.10 (Powers add nothing, at any number of scales). *As stated.*

Proof. (i) The proofs of Propositions 45.25(i)–(iii) and 45.26 use, of Picard–Vessiot theory over $\mathbb{C}(y)$, the Galois correspondence between intermediate differential fields and closed subgroups, the correspondence between submodules and invariant subspaces of the solutions, the restriction of the group of N onto the group of a construction from N, the equality of the transcendence degree of a Picard–Vessiot extension and the dimension of its group, and Kolchin's theorem on unipotent groups, which concerns the group alone. Each holds for several commuting derivations (Picard–Vessiot theory for partial differential fields, Kolchin's), so the proofs read verbatim over $\mathbb{C}(\mathbf{y})$.

(ii) For $\phi_u \in M_u$, $\partial_{y_e} \prod_u \phi_u = \sum_u (\partial_{y_e}\phi_u) \prod_{u' \neq u} \phi_{u'}$. So the multiplication of functions, from the tensor product of m_u copies of each M_u to the functions, is linear over $\mathbb{C}(\mathbf{y})$ and carries the tensor product of the connections to the derivations; it factors through $\bigotimes_u \operatorname{Sym}^{m_u} M_u$, the functions commuting, and its image I is a differential module, a quotient of $\bigotimes_u \operatorname{Sym}^{m_u} M_u$. I contains $\prod_u F_u^{m_u}$ and is closed under the derivations, so it contains the module that the product generates, a submodule of a quotient of a construction from $M_1 \oplus \cdots \oplus M_q$. A finite sum of such modules is a quotient of their direct sum, again a subquotient of a construction from $M_1 \oplus \cdots \oplus M_q$, and by (i) and Proposition 45.26(i) its group is the image of the group of $M_1 \oplus \cdots \oplus M_q$ acting on its solutions. □

Definition 48.11 (A tree of nested bunches). As stated.

Proof. (i) The node of Theorem 29.2(ii) has the seam letters of S with each child replaced by its stand-in at its seam point, and the stand-in of a piece at $\mathbf{x}$ enters a letter of table j through $\sum_D x_{jD} \alpha_g^{i(D)}$ in K_j and $\sum_D x^*_{jD} \alpha_g^{c_j - i(D)}$ in Ψ_j, linearly in $\mathbf{x}$ (Theorem 28.10(i), Lemma 28.8). Absorbing the children one at a time, the seam letters of the node are polynomials in α_{Z_S} and in the stand-ins, linear in the coordinates of each seam point, the coordinate x_{l,LD_l} carrying the power $\alpha_{g_l}^{\epsilon_L(D_l)}$; grouping the terms by the tuples of stations gives the entries, with the nonnegative coefficients of the letters. At the root the same holds for the stand-in core (Theorem 29.1). Read at $\alpha_{S_l} = \rho_l u_l$, $\alpha_{g_l} = \rho_l \gamma^{\rho}_{S_l}(u_l)$ and $\mathbf{x}_l = \boldsymbol{\varrho}^{\rho}_{S_l}(u_l)$, as in Theorem 29.1, the definitions of the seam vector and the degrees $d_L + \epsilon_L(D')$ of $V^{(l)}_{LD'}$ and d_L of $V^{(l),\mathrm{ext}}_L$ (Definition 28.5) give $x_{l,LD'} \alpha_{g_l}^{\epsilon_L(D')} = V^{(l)}_{LD'}(\alpha_{S_l}) / V^{(l),\mathrm{ext}}_L(\alpha_{S_l})$, and the seam letters of S are those of its node times $\prod_l V^{(l),\mathrm{ext}}_L$, the letters of the stand-in core being those of the family divided by the extreme excess sums of the pieces (Theorem 29.1); so $V_{LD} = \sum_{\mathbf{D}} \mathbf{N}_{S,L}(D;\mathbf{D}) \prod_l V^{(l)}_{LD_l}$.

(ii) The shares are those of Corollary 4.4, one family for each seam letter. A family of positive constants on no marks has the period $\prod_i c_i^{-w_i}$, the space of directions 0, and a module of dimension one (Definition 48.1). At a leaf there are no children, each seam letter is its one entry, and the node word is the seam word. For a chain, the node of S_l has the one child S_{l-1} and the seam letters

$\sum_{D'} x_{D'} \alpha_g^{i(D')} \mathbf{N}_l^K(D', D)$ and $\sum_{D'} x^*_{D'} \alpha_g^{c-i(D')} \mathbf{N}_l^\Psi(D', D)$ (Theorem 29.3(ii)), so its transfer tensor is the transfer matrix and its node word the word of the node l of Corollary 29.5. At width one the marks of a subtree cell are a bunch of width one of the table, and of the cells below it, nested as the cells are (Proposition 21.3(i),(ii)).

Normalizations. Multiplying the two seam letters of a station D of table j by $c_{jD} > 0$ and its room station letters by c_{jD}^{-1} is the normalization of the multipliers of the room sides of that station by another constant (the remark after Definition 28.1), so it keeps every product of a seam letter and a room station letter, and the bunch is a piece with the stations of its room whose glue with its room is the family (Definition 28.4, Proposition 28.2). Lemmas 28.7 and 28.8 and Theorem 28.10 are stated for pieces and their glue. Theorems 29.1 and 29.2(ii) are stated for bunches with the letters of Definition 28.1, and their proofs use of these letters only the writing $K_j = \sum_D V_{jD} L_{jD}$ of the letters of the family through them and the absorption of a piece (Lemma 28.8), so they hold for the letters $c_{jD} K_{j,(D)}$; the coefficients $w'_{q \sqcup X} / w'_X$ of Theorem 29.2(i) and the transfer matrices of Theorem 29.3(i) are those of the normalization of Definition 28.1, and in another they are multiplied by the constants. The seam word at the shares $(\mathbf{a}, \mathbf{b})$ is multiplied by $\prod c_{jD}^{-a_{jD}-b_{jD}}$, and so is its period, the seam function on the pins (Lemma 28.7); off the pins the seam function is a Mellin transform of the law, which the new extreme excess sums and scale move by a fixed bijection of the seam torus with a density (the paragraph after Definition 28.5). The second expression of Definition 28.21 gives the station transform $\mathbf{p} \mapsto \mathcal{I}(\mathbf{c} \circ \mathbf{p})$. In $V_{LD} = \sum_{\mathbf{D}} \mathbf{N}_{S,L}(D; \mathbf{D}) \prod_l V_{LD_l}^{(l)}$ the constants of the node multiply the left side and those of the children the factors on the right, which gives the change of the entries.

The gloss after the definition: the seam function on the pins is the period of the seam word (Lemma 28.7), which converges only if the word is full (Theorem 25.2), and the native split puts the masses of a full seam word in the relative interior of its Newton sum (Lemma 28.9); the seam word of the root is the family of the active letters of F, full since its marks form one molecule of the family of its active tables (Theorem 48.23(i)), the two letters of a table having one space of directions. □

Theorem 48.12 (A node on its shares; a tree of nested bunches is a share reading). *As stated.*

Proof. (i) The node is full. Let $v \in \mathbb{R}^{Z_S \sqcup \{g_1, \dots, g_k\}}$ be a direction on which every seam letter of the node is homogeneous, and let v' on S be v on Z_S and v_{g_l} on every mark of S_l. A monomial of $V_{LD} = \sum_{\mathbf{D}} \mathbf{N}_{S,L}(D; \mathbf{D}) \prod_l V_{LD_l}^{(l)}$ is a monomial of an entry times one monomial of each $V_{LD_l}^{(l)}$, of the degree $d_{l,L} + \epsilon_L(D_l)$ in α_{S_l}, so its value under v' is the value under v of the corresponding monomial of the node plus $\sum_l v_{g_l} d_{l,L}$, which depends on L alone; so every seam letter of S is homogeneous on v', and $v' \in \mathbb{R}\mathbf{1}_S$ since S is full, whence $v \in \mathbb{R}\mathbf{1}$. By Theorem 29.2(ii) the seam function of S at $\mathbf{a}_S$ is the integral against $\prod_l \lambda_l(d\mathbf{x}_l)$, λ_l the law of S_l, of the seam function of its node at $\mathbf{x}$, which on the pins is the period of the seam word of the node at the masses $(\mathbf{m}_{Z_S}, (\kappa_{S_l})_l)$, $\prod_{L,D} (V_{LD}^S)^{-a_{S,LD}}$ (Lemma 28.7). Open every seam letter of the node on its monomials, one share for each: its period is the fibre integral of the stacked Gammas $\Gamma_1 \begin{bmatrix} \cdot \\ a_{S,LD} \end{bmatrix}$ of the seam letters times the powers of the coefficients of the monomials, pinned by $|\cdot| = a_{S,LD}$ and by the masses of the marks of the node, by the share side of the Gramma (Proposition 4.2) applied as in the proof of Corollary 18.16, which uses of the letters only that their coefficients are positive. Group the monomials of each seam letter by their entries: the stacked Gamma of the seam letter at $a_{S,LD}$ is the stacked Gamma of its entries at their shares $e_{S,LD\mathbf{D}}$, the sums of the shares of their monomials, times the stacked Gammas of the monomials of each entry at $e_{S,LD\mathbf{D}}$, $\prod_k \Gamma(b_k)/\Gamma(a) = \big(\prod_E \Gamma(e_E)/\Gamma(a)\big) \prod_E \big(\prod_{k \in E} \Gamma(b_k)/\Gamma(e_E)\big)$.

The masses of the own marks pin only the shares inside the entries, the exponents of α_{Z_S}; those of the stand-ins pin only the entry shares, the exponent of α_{g_l} in a monomial of the entry $(L, D; \mathbf{D})$ being $\epsilon_L(D_l)$, and $\sum e_{S,LD\mathbf{D}}\,\epsilon_L(D_l) = \kappa_{S_l}$ is the scale pin of S_l at its loads (Lemma 28.7), the loads of a letter at S_l summing to $\sum_D a_{S,LD} = s_L$. The seam coordinates appear in the coefficients as $\prod_l \mathbf{x}_l^{-\mathbf{a}_{S_l}}$, the exponent of $x_{l,LD'}$ being the load at D'. So the inner fibre, over the shares inside the entries, is the period of the node word at the entry shares opened on its monomials (Proposition 4.2 again), with transverse pins in the directions of Z_S that the node word does not see (Theorem 28.12), and integrating against the laws, $\int \mathbf{x}_l^{-\mathbf{a}_{S_l}}\,d\lambda_l(\mathbf{x}_l)$ is the seam function of S_l at its loads (Definition 28.5). The pins so obtained are dependent: every monomial of the entry $(L, D; \mathbf{D})$ has the degree $\deg V^S_{LD} - \sum_l \epsilon_L(D_l)$ in α_{Z_S}, so the homogeneity of the node word, $m_{Z_S} = \sum e_{S,LD\mathbf{D}}\big(\deg V^S_{LD} - \sum_l \epsilon_L(D_l)\big)$, is $\sum_{L,D} \deg V^S_{LD}$ times the totals less the scale pins of the children, by the balance $m_{Z_S} + \sum_l \kappa_{S_l} = \sum_{L,D} a_{S,LD} \deg V^S_{LD}$ of the seam word of the node at shares on its pins; when Z_S is empty the scale pins of the children add up to $\sum_{L,D} \deg V^S_{LD}$ times the totals. There is no other: if the totals with coefficients x_{LD}, the scale pins with coefficients y_l and the pins of directions with a vector $w \in \vec{\mathcal{N}}^{\perp}_{W_S}$ add up to zero, then on every entry $(L, D; \mathbf{D})$, $x_{LD} + \sum_l y_l \epsilon_L(D_l) + \langle \mathbf{t}, w\rangle = 0$ for the exponents $\mathbf{t}$ of its monomials, so the vector equal to w on Z_S and to y_l on g_l is a direction on which every seam letter of the node is homogeneous, a multiple of $\mathbf{1}$, the node being full, and the combination is a multiple of the dependence. Dropping that one pin leaves linearly independent rows, on which the fibre of Definition 4.1 is read. The exchanges are Fubini's theorem: on the contour $|\mathbf{x}^{-\mathbf{z}}| = \mathbf{x}^{-\operatorname{Re}\mathbf{z}}$ and the period of a family of positive letters is at most its value at the real parts, so it suffices that the stacked Gammas be integrable along the fibre. By Stirling's formula, uniformly for real parts in a compact subset of $(0, \infty)$, they are at most $C(1 + |\mathbf{y}|)^n e^{-\frac{\pi}{2}E(\mathbf{y})}$, $\mathbf{y}$ the imaginary parts, with $E(\mathbf{y}) = \sum_{L,D} \big(\sum_{\mathbf{D}} |y_{LD\mathbf{D}}| - |\operatorname{Im} a_{S,LD}|\big) \geq \sum |y_{LD\mathbf{D}}| - 2\sum_{L,D} |\operatorname{Im} a_{S,LD}|$, so $E(\mathbf{y}) \geq \varepsilon|\mathbf{y}| - C$ on the fibre, with C bounded for the loads in a compact set. At the root the letters of the stand-in core and the exponents s_L take the place of the seam letters and their shares (Theorem 29.1). With one child the entries are the transfer matrices from S_1 to S (Definition 48.11(ii)), and the display is that of Theorem 29.6(iii); at a leaf the entries are the seam letters, every stacked Gamma is 1, and the display is Lemma 28.7. With the node word opened on its monomials what is left of the node is the stacked Gammas and the powers of the coefficients. At width one for one table on its centre ray the node of a subtree cell is the family of the two hinge minors of its core with its cells at their markers, and that of the root the core with its cells (Proposition 42.26(iii),(v)); the monomials of the entries are the bases of these tables, and the display with the node words opened is (iii) and (v) there.

(ii) In this proof every letter is active: an inactive letter enters no period (Definition 28.5), P_F is the period of the family of the active letters, and that family is full, its period converging, every proper wall being positive (Theorems 8.7 and 25.2), so its marks form one molecule in the tables of its letters (Theorem 48.23(i)), the two letters of a table having one space of directions. The *groups* are the own marks Z_S of the nodes with $Z_S \neq \varnothing$ and the marks of the leaves. They partition $\mathcal{E}$, and each carries its *word*, the node word of its node or the seam word of its leaf, whose data are its masses and the shares of its letters: the entry shares at a node, the loads at a leaf.

The path of a basis. For a basis T of the table of an active letter L every node $S \neq \mathcal{E}$ has the station $D_S(T)$ of the room side $T \setminus S$ in that table, and T runs through the entry $E_S(T) = \big(D_S(T); (D_{S_l}(T))_l\big)$ of every node S that is not a leaf, $D_{\mathcal{E}}$ dropped. The term of T in L is the product of one monomial of each of these entries, $\alpha^{T\cap Z_S}$ for $L = K_j$ and $\alpha^{Z_S\setminus T}$ for $L = \Psi_j$, times its coefficient, and of the monomials $\alpha^{T\cap S}$ or $\alpha^{S\setminus T}$ of the seam letters of the leaves at their stations (Definition 48.11(i), Theorem 29.2(i)). Let τ_T put 1 on the share of every entry $E_S(T)$ of L and 0 on every other share, and let λ_T be the data of the stride α^T/K_j or $\alpha^{\mathcal{E}\setminus T}/\Psi_j$.

The reading identity. By Definition 48.11(i), applied at every node from the root down, every active letter L of F is the sum, over the families of stations $(D_S)_{S\neq\mathcal{E}}$, one station of every node other than the root in the table of L, of the products over the nodes of the entries $\mathbf{N}_{S,L}(D_S;(D_{S'})_{S'})$, S' running over the children of S and $D_{\mathcal{E}}$ dropped, times the products over the leaves of their seam letters $V^{(S)}_{LD_S}$. Open L^{-s_L} on the entries of the root (Corollary 4.4), and then, at every child S of a node already opened and every station D of S, the power of the seam letter of S at D at its load on the entries of S at D, multiplying and dividing by the Gamma of the load: this is the computation of Corollary 29.5 along the tree, a node with several children carrying one share for each tuple of stations of its children, and its integrand is the kernel of (ii) times the product over the groups of the powers of the letters of their words. Integrated over the marks of F against $\alpha^{\mathbf{m-1}}$, by the argument of Theorem 28.12 with the groups in place of its two sides, this is the fibre integral of the periods of the words of the groups, reduced where their Newton sums are degenerate, pinned in the directions that each word does not see, less the one homogeneity of F, which holds by the letter totals on the balance wall. Where every node is full, the scale pin of a node is the sum of the pins of the scalings of the groups inside it, and the reading is (i) composed node by node from the root, by Theorem 48.5(vi), each composition dropping the homogeneity of the node read, the scale pin it shares with its parent.

The share space. The pins are the letter totals at the root, the conservation at every station of every node other than the root and the leaves, and the pins of directions of the words of the groups, taken on bases of the lattices $\vec{\mathcal{N}}^{\perp}\cap\mathbb{Z}^G$ of their words that contain the indicators $\mathbf{1}_G$. The totals and the conservation are independent: in a vanishing combination of them, take a node all of whose descendants that are not leaves have only the coefficient 0 at their stations; a share of an entry of that node out of a station enters the conservation at that station with the coefficient 1 and otherwise only the conservation at stations of its children, so the coefficient of the conservation at every station of that node, which has an entry out of it, is 0; from the lowest nodes up every coefficient of a conservation pin is 0, and then those of the totals. If a combination of the pins of directions, with vectors v_G in the spaces $\vec{\mathcal{N}}^{\perp}$ of the words, is a combination of the totals and the conservation, its value at τ_T is $\langle\mathbf{1}_T,w\rangle$, w being v_G on each group G and τ_T moving the word of G by the exponent $\mathbf{1}_{T\cap G}$ of the term of T in its letter, and it equals the coefficient of the letter total of L, τ_T keeping the conservation; likewise with $\langle\mathbf{1}_{\mathcal{E}\setminus T},w\rangle$ for the cobasis letters. So these values are constant over the bases of the table of every active letter, w is constant (Lemma 7.8, these tables forming one molecule), and every v_G is the same multiple of $\mathbf{1}_G$. The sum of the homogeneities is the combination of the totals and the conservation given by the balance, as in the proof of Theorem 48.7(i), the total degree of the shares telescoping through the conservation to $\sum_L s_L\deg L$; so it is the one dependence, and the pins less one homogeneity are independent. The forms of the kernel, the shares and the loads are integral on the lattice of the share space, and the maps to the words of the groups are coordinate maps, integral on it.

The maps are onto. Every station of a node other than the root has a nonzero entry of its parent into it and, when the node is not a leaf, a nonzero entry of its own out of it, those of the path of a basis through it. Given data of the word of one group, the loads that its shares put on the stations of its node and of the children of its node are carried by shares of the neighbouring entries, up to the root, whose totals give the exponents of F, and down to the leaves, whose loads are the loads carried; masses of the other groups on the pins of their directions exist, the masses of a word ranging over a translate of the complexified space of its directions, and the data so obtained lie on the balance wall by the balance. So every map to the word of a group is onto. For a full node $S\neq\mathcal{E}$ the same argument applies to its seam word at shares on the pins of its seam, a family of positive letters whose period is the seam function of S (Lemma 28.7) and whose letters are the

seam letters of S, opened along its subtree: the sums $\sum_{\mathbf{D}} e_{S,LD\mathbf{D}} = a_{S,LD}$ take the place of the letter totals, its homogeneity is the scale pin of S, and the native split of F on the subtree, with the native loads of S, is an admissible point.

The identity at all data. At a real $\mathbf{d}$ with an admissible $\mathbf{c}$ (below) the shares are positive and the words of the groups converge at their data, which lie in their tubes; the reading identity holds there and its fibre integral converges absolutely (below), so $P_F(\mathbf{d})$ is finite, every proper wall is positive (Theorem 8.7), and $\mathbf{d} \in \mathcal{T}_1(F)$. At complex data both sides are holomorphic on the tube over the projection of $\mathbb{S}^+$, which is connected, and they agree at its real points, as in the proof of Theorem 48.7(i), *The identity*; so they agree on it.

Absolute convergence. The composed kernel is the product over the opened nodes of their stacked Gammas, and Stirling's formula bounds it by $C(1 + |\mathbf{y}|)^n e^{-\frac{\pi}{2}E(\mathbf{y})}$ with $E(\mathbf{y}) = \sum_S \sum_{L,D} \big(\sum_{\mathbf{D}} |y_{S,LD\mathbf{D}}| - |A_{S,LD}| \big)$, $A_{S,LD}$ the imaginary part of the load of S at (L, D), 0 at the root, where the shares are the real exponents. Every bracket is nonnegative. If $E(\mathbf{y}) = 0$ the shares at the root are real, so the loads of its children are, so their shares are, the brackets there vanishing with $A = 0$, and so on down the tree: $\mathbf{y} = 0$. As in the proof of Theorem 48.7(i), $E(\mathbf{y}) \geq \varepsilon|\mathbf{y}|$ on the fibre and the fibre integral converges absolutely, uniformly for real parts in a compact set.

Admissible points. At real data with a native gauge $\alpha^\star$ put $e_{S,LD\mathbf{D}} = s_L \, \mathbb{P}_{L,\alpha^\star}\big(T \setminus S \in D,\ (T \setminus S_l \in D_l)_l\big)$, the joint native probability of the stations of the room sides of a basis T (Definition 12.25), which is positive exactly at the nonzero entries, the bases of each rectangle making the term of the entry (Proposition 28.2(ii)), and whose marginals give the conservation at every station. At these shares the masses of every node word and of every leaf lie in the relative interiors of their Newton sums, the native split being the expectation of the exponents of the monomials under the native law, as in Lemmas 28.9 and 29.4, so they lie in their tubes (Theorem 48.3(i)), on the pins of their directions where a Newton sum is degenerate. These data form a nonempty open set of real points of the data space of the family of the active letters, the realizations of the active tables at the exponents of the active letters among them (Definition 9.1, Propositions 8.22 and 9.2), the centre data when every letter is active; the pins are linear, so every $\mathbf{d}$ has shares on them, and the reading is positive.

The lattice. $(\lambda_T, \tau_T) \in \mathbb{S}(\mathbb{Z})$: τ_T adds 1 to the letter total of L, which λ_T raises by one, and to the in- and the out-load of every station $D_S(T)$, keeping the conservation, and it moves the word of every group by the data of the stride of its piece of T, $(\mathbf{1}_{T\cap Z_S}; \mathbf{e}_{E_S(T)})$ at a node and $(\mathbf{1}_{T\cap S}; \mathbf{e}_{D_S(T)})$ at a leaf for K_j, keeping its pins of directions, the difference of two exponents of one letter lying in its space of directions. By the circuit argument of the proofs of Theorems 48.7(iii) and 48.23(i) the data of the strides of the bases, for the active letters K_j, and of the cobases, for the active letters Ψ_j, span the lattice of the data of the family of the active letters, its marks forming one molecule in the tables of its letters; so $\mathbb{S}(\mathbb{Z})$ maps onto that lattice, $\mathfrak{M}'_F = \mathfrak{M}_F$ for the module $\mathfrak{M}_F$ of that family, and Theorem 48.5(iii) reads every element of $\mathfrak{M}_F$.

(iii) A bijection of the marks of two nodes keeping their seam letters, with the stations of their children corresponding, carries the coefficient of each product of seam coordinates in the seam letter of one node to that of the corresponding product in the other, so the entries correspond and the bijection of the own marks with that of the entries is an isomorphism of the node words; for leaves the seam letters correspond. Theorem 48.5(v) applies.

(iv) The real data and shares of (i) form a convex set: on the balance wall the exponents of the letters and the proper walls are positive on a convex cone, a native gauge exists at every point of it, the density $\omega_{\mathbf{d}}/dy$ of the master form of the family of the letters of F at real data with positive exponents and positive walls having one critical point on the orthant, a nondegenerate maximum

(the argument of Proposition 47.14(i), which uses of a native direction only these properties), and the shares of (i) are cut out by strict linear inequalities and by the convergence of the seam functions and the node word, each on an open convex set of its real data. The tube over this set is connected. At a complex point of it the left side of (i) is the integral of $(\boldsymbol{\varrho}_S^{\rho})^{-\mathbf{a}_S}$ against the scale form at complex masses, whose modulus is the integrand at the real parts, $|\alpha^{\mathbf{m}}| = \alpha^{\operatorname{Re}\mathbf{m}}$ and $|L^{-s}| = L^{-\operatorname{Re}s}$ on the orthant; on the right the node word and the seam functions of the children have the same bound at the real parts of their data and loads, fixed along the contour, and the stacked Gammas of one seam letter, whose shares have the total $a_{S,LD}$ fixed by its pin, decay exponentially along the fibre in the spread of the imaginary parts of their shares, by Stirling's formula, while the scale pins and the pins of directions are linear. So both sides converge absolutely and locally uniformly, and they are holomorphic on the tube; they agree at its real points, a set of real points of maximal dimension, and so on all of it. For (ii), Definition 48.4 reads the reading identity at every complex $\mathbf{d}$ at which a real $\mathbf{c}$ is admissible, and the proof of (ii) gives it there. □

Definition 48.13 (Blocks of a node; its scales and the transforms of its blocks). As stated.

Proof. (i) In a monomial whose present parts all lie in P, dividing by A_L leaves its coefficient times the ratios of the children of P present in it and the powers $\alpha_z^{q-u_{z,L}}$ of the own marks of P present in it, the absent parts contributing 1; a monomial without present parts is the constant part. Summing over the monomials gives the bracket, with nonnegative coefficients. A partition is separated exactly when the present parts of every monomial lie in one block, that is when every two parts present in one monomial lie in one block, that is when every class of the relation they generate lies in one block.

(ii) The node is a piece (Theorem 29.2(ii)), so its seam letters are homogeneous (Definition 28.4), and A_L is a monomial in its marks; so every reading at (L, D) is homogeneous of the degree δ_{LD}, and where $n_L(D) \neq 0$, A_L is a monomial of V_{LD}^S and $\delta_{LD} = 0$. The action on the scales is linear in their logarithms, and free exactly when some δ_{LD} on Σ_S is not zero. If it is not free and the node separates a partition with two blocks $P \neq P'$, every reading has the degree 0 and lies in the marks of its own block, so every monomial of a seam letter of the node has the degree of A_L in the marks M_P of the node of the parts of P: every seam letter of the node is homogeneous along $\mathbf{1}_{M_P}$, which is not a multiple of $\mathbf{1}_M$, and the node is not full, nor is S (proof of Theorem 48.12(i)).

(iii) The integrands are positive and measurable, so the transforms are defined in $[0, \infty]$. When the node is not seen by its scales the common scaling of the marks of all the parts multiplies each $V_{LD'}^{(l)}$ by $e^{t(d_{l,L}+\epsilon_L(D'))}$, so it keeps every ratio of a child at the degree $\epsilon_L(D') - \epsilon_L(D_{l,L}^{\circ})$, and keeps every term of every reading, of the degree $\delta_{LD} = 0$; it multiplies the rest of the integrand by e^{tc} with $c = \sum_l \left(\kappa_{S_l} - \sum_L s_L \epsilon_L(D_{l,L}^{\circ})\right) + \sum_z \left(m_z - \sum_L s_L u_{z,L}\right) = \sum_z m_z + \sum_l \kappa_{S_l} - \sum_L s_L \deg A_L$, the walls being $\kappa_{S_l} = m_{S_l} - \sum_L s_L d_{l,L}$; on the balance of the seam word of the node at shares on the pins, $\sum_z m_z + \sum_l \kappa_{S_l} = \sum_{L,D} a_{LD} \deg V_{LD}^S = \sum_L s_L \deg A_L + \sum_{L,D} a_{LD}\delta_{LD}$, so $c = 0$ and the integrand is invariant. A block without children has the integral over its own marks of a monomial times the exponential of minus a sum of monomials with coefficients linear in the scales, a Gramma. A bijection of marks keeping seam letters and masses carries the integrand of one transform to the other's when the absent stations and exponents correspond and the readings are equal. □

Theorem 48.14 (A node on its scales). *As stated.*

Proof. (i) By Theorem 29.2(ii) and Lemma 28.7 the seam function of S at $\mathbf{a}$ is the integral against the laws $\lambda_l(d\mathbf{x}_l)$ of the children of $\int_V \mu(\alpha) \prod_{L,D} (V_{LD}^S)^{-a_{LD}}\, dy$, $V = \mathbb{R}^M/\mathbb{R}\mathbf{1}$ in the coordinates

$y = \log\alpha$, with the quotient of Lebesgue measure by dt, and $\mu(\alpha) = \alpha^{\mathbf{m}_Z}\prod_l \alpha_{g_l}^{\kappa_{S_l}}$. On the pins $\sum_D a_{LD} = s_L$, so $\prod_D (V_{LD}^S)^{-a_{LD}} = A_L^{-s_L}\prod_D \rho_{LD}^{-a_{LD}}$, ρ_{LD} the bracket, which is the constant $n_L(D) > 0$ off Σ_S, the seam letter being nonzero. For $(L,D) \in \Sigma_S$ and $a > 0$, $\Gamma(a)\rho^{-a} = \int_0^\infty \xi^a e^{-\xi\rho}\,d\xi/\xi$. So the left side of (i) is, by Tonelli's theorem, the integral against the laws of

$$\int_{V\times(0,\infty)^{\Sigma_S}} \mu(\alpha)\prod_L A_L^{-s_L}\,\boldsymbol{\xi}^{\mathbf{a}} \exp\Big(-\sum_{(L,D)\in\Sigma_S}\xi_{LD}\rho_{LD}\Big)\,dy\,\frac{d\boldsymbol{\xi}}{\boldsymbol{\xi}}.$$

Let $t \in \mathbb{R}$ act on $\mathbb{R}^M \times (0,\infty)^{\Sigma_S}$ by $y \mapsto y + t\mathbf{1}$ and $\xi_{LD} \mapsto e^{-t\delta_{LD}}\xi_{LD}$. Each $\xi_{LD}\rho_{LD}$ is kept, the bracket being homogeneous of the degree δ_{LD} (Definition 48.13(ii)), and $\mu\prod_L A_L^{-s_L}\boldsymbol{\xi}^{\mathbf{a}}$ is multiplied by e^{tc} with $c = \sum_z m_z + \sum_l \kappa_{S_l} - \sum_L s_L \deg A_L - \sum_{L,D} a_{LD}\delta_{LD} = \sum_z m_z + \sum_l \kappa_{S_l} - \sum_{L,D} a_{LD}\deg V_{LD}^S$, which vanishes on the data space of the seam word of the node, where the shares on the pins of the seam lie. The integral over $V \times (0,\infty)^{\Sigma_S}$ is the integral over the quotient of $\mathbb{R}^M \times (0,\infty)^{\Sigma_S}$ by the action, the action being free on $\mathbb{R}^M$, with the quotient of the product measure by dt. When S is seen by its scales the action is free on $(0,\infty)^{\Sigma_S}$ too, and the integral over the quotient is the integral over $\Xi_S \times \mathbb{R}^M$; when it is not, the action is trivial on the scales, and it is the integral over $(0,\infty)^{\Sigma_S} \times (\mathbb{R}^M/\mathbb{R}\mathbf{1})$. At fixed scales the integrand factors over the parts and the blocks: $\mu\prod_L A_L^{-s_L} = \prod_l \big(\prod_L x_{l,LD_{l,L}^\circ}^{-s_L}\,\alpha_{g_l}^{\kappa_{S_l} - \sum_L s_L\epsilon_L(D_{l,L}^\circ)}\big)\prod_z \alpha_z^{m_z - \sum_L s_L u_{z,L}}$, and the exponential is $e^{-\langle\boldsymbol{\xi},\mathbf{n}\rangle}$ times one factor $\exp(-\sum \xi_{LD}\beta_{P,LD})$ for each block, which involves the marks of the node of the parts of P alone, the node separating $\mathcal{P}$. When S is seen by its scales the integral over $\mathbb{R}^M$ is therefore $e^{-\langle\boldsymbol{\xi},\mathbf{n}\rangle}$ times the product over the blocks of the integrals over the marks of their parts; when it is not, there is one block and the integral is over $\mathbb{R}^M/\mathbb{R}\mathbf{1}$. Integrate the factor of a block against the laws λ_l, $l \in P$, the images of the $\phi_{S_l}^\rho$ under the $\boldsymbol{\varrho}_{S_l}^\rho$, and substitute $\alpha_{g_l} = \rho_l\,\gamma_{S_l}^\rho(u_l)$ at a fixed shape u_l and then $\alpha_{S_l} = \rho_l u_l$ (the computation of Definition 28.21): $x_{l,LD'}\alpha_{g_l}^{\epsilon_L(D')}$ becomes $V_{LD'}^{(l)}(\alpha_{S_l})/V_L^{(l),\mathrm{ext}}(\alpha_{S_l})$ (proof of Definition 48.11(i)), so the absent factors become $\prod_L \big(V_{LD^\circ}^{(l)}/V_L^{(l),\mathrm{ext}}\big)^{-s_L}$ and the ratios of the children $V_{LD'}^{(l)}/V_{LD^\circ}^{(l)}$; and $\rho_l^{\kappa_{S_l}-1}u_l^{\mathbf{m}_{S_l}-\mathbf{1}}\prod_L V_L^{(l),\mathrm{ext}}(u_l)^{-s_L}\,d\rho_l\,d\omega(u_l) = \alpha_{S_l}^{\mathbf{m}_{S_l}-\mathbf{1}}\prod_L V_L^{(l),\mathrm{ext}}(\alpha_{S_l})^{-s_L}\,d\alpha_{S_l}$, the wall being $\kappa_{S_l} = m_{S_l} - \sum_L s_L d_{l,L}$ (Definition 28.4), the scale $\gamma_{S_l}^\rho$ cancelling its power in $\phi_{S_l}^\rho$. The result is $\mathcal{T}_P(\boldsymbol{\xi})$, by Tonelli's theorem; when S is not seen by its scales the common scaling of α_M becomes that of the marks of all the parts, and the result is the transform over the quotient. Equal blocks give equal factors. At complex shares $|\boldsymbol{\xi}^{\mathbf{a}}| = \boldsymbol{\xi}^{\mathrm{Re}\,\mathbf{a}}$ and $|(V_{LD}^S)^{-a}| = (V_{LD}^S)^{-\mathrm{Re}\,a}$, so the same computation holds by Fubini's theorem where the left side at the real parts is finite. At the root Theorem 29.1 gives P_F as the integral against the laws of the period of the stand-in core, and the same computation holds with its letters and the exponents s_L. At complex data the masses enter the integrand through μ and the exponents through the powers of the letters, and on the orthant $|\alpha^{\mathbf{m}}| = \alpha^{\mathrm{Re}\,\mathbf{m}}$ and $|L^{-s}| = L^{-\mathrm{Re}\,s}$; so both sides are bounded in modulus by their integrands at the real parts, converge absolutely and locally uniformly on the tube over the real data and shares of (i), which is convex, and are holomorphic there. They agree at its real points, and so on it.

(ii) The transform is the integral against the laws of the children of a function of their seam points, by the substitution of (i) read backwards, so it depends on them only through their laws and their walls, the masses of the stand-ins. If the left side of (i) is finite, the integrand on the right is finite at almost every point of Ξ_S, so, being invariant on the orbits, at almost every point of $(0,\infty)^{\Sigma_S}$; its factors are positive, so each $\mathcal{T}_P$ is finite at some $\boldsymbol{\xi}$. It is $\langle 1\rangle_{\boldsymbol{\nu}}$ of Lemma 48.8 on the marks of its children and its own marks, over the quotient by the common scaling when S is not seen by its scales (part (iii) there): the h_k are the absent letters $V_{LD_{l,L}^\circ}^{(l)}$ of its children, with the exponents s_L, the R's the $\widehat{\beta}_{P,LD}$, each a polynomial with nonnegative coefficients in the seam

letters of the children and the own marks over the product of the absent letters of the children and a monomial in the own marks, and the masses those of the children and $m_z - \sum_L s_L u_{z,L}$ on the own marks. By the lemma it converges at every $\boldsymbol{\xi}$, with all its derivatives, and generates a differential module of finite rank over $\mathbb{C}(\boldsymbol{\xi})$. The substitution $\alpha \mapsto e^t \alpha$ on the marks of P gives $\mathcal{T}_P(\boldsymbol{\xi}) = e^{tc_P} \mathcal{T}_P\big((e^{t\delta_{LD}} \xi_{LD})_{LD}\big)$ for a constant c_P, so the singular locus of its module is invariant under the action, and a section of the scale quotient by a monomial map, which meets every orbit, is not contained in it; the restrictions of a basis of the derivatives to the section span the derivatives of the restriction, the derivatives of the section being Laurent monomials, and they span a module of finite rank over the rational functions of the section. For the display, let the left side of (i) be finite at some shares and the children of P be full, and take the factor of the block in (i) before the substitution, the integral against the laws λ_l, $l \in P$, of an integral over the stand-ins and the own marks of P. At fixed seam points of the children that inner integral is a Gramma on these marks (Definition 2.1): its configuration is the exponents of the monomials τ of the readings, $\epsilon_L(D') - \epsilon_L(D^\circ_{l,L})$ on the stand-in of a child present at D' and $q - u_{z,L}$ on an own mark, its coefficients are the $\xi_{LD} c_\tau$ times the ratios of the seam coordinates in τ, and its index is the masses $\kappa_{S_l} - \sum_L s_L \epsilon_L(D^\circ_{l,L})$ of the stand-ins and $m_z - \sum_L s_L u_{z,L}$ of the own marks; when S is not seen by its scales it is taken over the quotient by the common scaling, on a section a Gramma on one mark fewer (Lemma 48.8(iii)). Its index and configuration do not depend on the seam points, so it converges at every seam point once it converges at one (Theorem 2.2), as it does when $\mathcal{T}_P$ is finite. By its share side (Proposition 4.2) it is the fibre integral of $\prod \Gamma(z_{LD\tau})$ times the powers $-z_{LD\tau}$ of its coefficients, pinned by its index: these are the pins of the block, the pin of the common scaling holding identically when S is not seen by its scales. The powers of the seam coordinates, with $\prod_L x_{l,LD^\circ}^{-s_L}$, are $\mathbf{x}_l^{-\mathbf{a}_l}$ at the loads stated. Integrating against the laws, by Fubini's theorem, the Gammas decaying exponentially along the fibre and $|\mathbf{x}^{-\mathbf{z}}| = \mathbf{x}^{-\operatorname{Re}\mathbf{z}}$, gives the display, $\int \mathbf{x}_l^{-\mathbf{a}_l}\, d\lambda_l$ being the seam function of S_l at its loads. With a native gauge $\alpha^\star$ put $z_{LD\tau} = s_L\, \mathbb{P}_{L,\alpha^\star}(\tau)$, the native probability of the bases whose term in L runs through the monomial τ of the seam letter of the node at D, as in the proof of Theorem 48.12(ii): these are positive; the load of a child at a station is its native load there, by the marginals, at which its seam function converges, the child being full (Lemma 28.9); the scale pins of the children hold there; and for an own mark z of P, $m_z = \sum_{L,\tau} z_{L\tau} q_{z,\tau}$ over all the monomials of the seam letters at L, the native split being the expectation of the exponents, while the monomials in which P is absent have $q_{z,\tau} = u_{z,L}$ and the shares of all the monomials at L add up to s_L, so the pin of z holds. So this point lies on a contour of the display.

(iii) A series or a parallel node with unit weights is the series or the parallel connection of its cells (Definition 23.13). With factoring weights a bunch of width one has one station of each excess in every letter, and its seam letters at the excesses 0 and 1 are, up to positive constants, the letters of the hinge minors $\mathcal{A}/g_0$ and $\mathcal{A} \setminus g_0$ of its cell (Proposition 28.11, the letters at the extreme levels); in the normalization of the statement the constants are 1, the cell carrying its own weights (Definition 23.15), and the entries of a node are the weights of the bases of its core, times the norms at the root. A cell $\mathcal{A}_i$ enters a basis of the substitution through a basis of $\mathcal{A}_i \setminus g_i$, its excess 1, when its marker lies in the basis of the core and through a basis of $\mathcal{A}_i/g_i$, its excess 0, when it does not, in both letters (Definition 21.1); a mark left in place enters through itself or through nothing. At a parallel node the bases of $\binom{G}{1}/g_0$ are $\varnothing$ and those of $\binom{G}{1} \setminus g_0$ the single markers, so every term of the seam letters at the excess 0 has every cell at its excess 0, and every term at the excess 1 has one cell at its excess 1 and the others at 0: separable with the absent stations of the excess 0, the absent exponents 0 in K and 1 in Ψ for a mark. At a series node the bases of $\binom{G}{q} \setminus g_0$ are $\{g_1, \dots, g_q\}$ and those of $\binom{G}{q}/g_0$ omit one marker, so it is separable with the

absent stations of the excess 1, the absent exponents 1 in K and 0 in Ψ. Each term carries the weight of its basis of the core, so the readings and the constant parts are weights of the core, 1 with the weights 1. The constant parts are 0 on Σ_S, which is $\{(K,D_1),(\Psi,D_1)\}$ at a parallel node and $\{(K,D_0),(\Psi,D_0)\}$ at a series node. The brackets have the degrees 1 and -1 in the stand-ins at a parallel node, -1 and 1 at a series node, so the node is seen by its scales, and the scale quotient is the line of $y=\xi_K\xi_\Psi$, with dy/y. With the weights 1, at a parallel node the transform of a cell is $\int \alpha^{\mathbf{m-1}} K_{\mathcal{A}/g}^{-s}\Psi_{\mathcal{A}/g}^{-t}\exp\big(-\xi_K\gamma_{\mathcal{A}}^K-\xi_\Psi/\gamma_{\mathcal{A}}^\Psi\big)\,d\alpha$, $\gamma_{\mathcal{A}}^K=K_{\mathcal{A}\backslash g}/K_{\mathcal{A}/g}$ and $\gamma_{\mathcal{A}}^\Psi=\Psi_{\mathcal{A}/g}/\Psi_{\mathcal{A}\backslash g}$ (Definition 21.1), which is $\check f_F(\xi_\Psi,\xi_K)$ and at $(\xi_K,\xi_\Psi)=(y,1)$ is $\check f_{\mathcal{A}}(y)$ (Definition 23.1); at a series node it is $\int \alpha^{\mathbf{m-1}} K_{\mathcal{A}\backslash g}^{-s}\Psi_{\mathcal{A}\backslash g}^{-t}\exp\big(-\xi_K/\gamma_{\mathcal{A}}^K-\xi_\Psi\gamma_{\mathcal{A}}^\Psi\big)\,d\alpha$, which is $f_F(\xi_K,\xi_\Psi)$ and at $(1,y)$ is $f_{\mathcal{A}}(y)$. A mark left in place has $\mathsf{G}_{m_e-t;(1,-1)}(\xi_K,\xi_\Psi)$ at a parallel node and $\mathsf{G}_{m_e-s;(1,-1)}(\xi_\Psi,\xi_K)$ at a series node, which on the sections are the transforms of the one-mark cell of ratio 1 of Definition 23.19(1), by the torus homogeneity and the reflection $v\mapsto 1/v$ of the Gramma on one scale. On the section $\xi_\Psi=1$ of a parallel node $\boldsymbol{\xi}^{\mathbf{a}}=y^{a_{K,D_1}}$, and on the section $\xi_K=1$ of a series node $\boldsymbol{\xi}^{\mathbf{a}}=y^{a_{\Psi,D_0}}$, the pins of the seam giving $a_{\Psi,D_1}=a_{K,D_1}+t-\kappa$ and $a_{K,D_0}=a_{\Psi,D_0}+s-\kappa$, κ the wall of the bunch. So (i) is the one Trailmoment $\int_0^\infty y^{a_{K,D_1}}\prod_i \check f_{\mathcal{A}_i}(y)\,dy/y$ at a parallel node, against $\Gamma(a_{K,D_1})\Gamma(a_{K,D_1}+t-\kappa)$, and $\int_0^\infty y^{a_{\Psi,D_0}}\prod_i f_{\mathcal{A}_i}(y)\,dy/y$ at a series node, against $\Gamma(a_{\Psi,D_0})\Gamma(a_{\Psi,D_0}+s-\kappa)$: the rule of Definition 23.19(2), and at the root (5), the root having the letters K and Ψ without stations. At a series node the transforms of the cells multiply, which is Proposition 20.37(i) with the transforms of the parts. On the centre ray, $s=t=k$, the masses k and the hinge walls k, the shares of the scaled stations of a cell at the load ℓ of its marker are ℓ at a parallel node and $k-\ell$ at a series node, the constant parts 1 off Σ_S, and (i) reads $\Gamma(\ell)^2\widehat{\mathsf{V}}_{\mathcal{A}}(k;\ell)=\int_0^\infty y^{\ell-1}\prod_i \check f_{\mathcal{A}_i'}(y)\,dy$ and $\Gamma(k-\ell)^2\widehat{\mathsf{V}}_{\mathcal{A}}(k;\ell)=\int_0^\infty y^{k-\ell-1}\prod_i f_{\mathcal{A}_i'}(y)\,dy$, with $\widehat{\mathsf{V}}_{\mathcal{A}}(k;\ell)$ the seam function at these shares (Proposition 42.26(iv)): Proposition 42.26(vi). At the root the letters are K of $(\mathcal{B},\theta)$ at the exponent k and the cobasis letter $\Psi_{\theta\mathsf{m}}$ at k, whose term at a basis T carries $\prod_{e\in T}\mathsf{m}_e$ (Proposition 42.26(i)), the norms being 1 on the marks of the cells. At a parallel root a basis of the core is one marker, so the term of $\Psi_{\theta\mathsf{m}}$ in which a mark e left in place is present carries m_e and no other norm: its reading is m_e, and its transform $\mathsf{G}_{0;(1,-1)}(\xi_K,\mathsf{m}_e\xi_\Psi)=\mathsf{g}(\mathsf{m}_e y)$, by the torus homogeneity at the index 0. At a series root a basis of the core omits one marker, so the term in which a part is present carries the norms of all the marks left in place but its own: every reading in Ψ is M divided by the norm of the part, and in the coordinate $y=M\xi_K\xi_\Psi$, on the section $\xi_K=M^{-1}$ where $y=\xi_\Psi$, the transforms are $\mathsf{g}(y/\mathsf{m}_e)$ and $f_{\mathcal{A}}(y)$, while $\boldsymbol{\xi}^{\mathbf{s}}$ carries $M^{-k}=\prod_e \mathsf{m}_e^{-k}$. So (i) at the root is Proposition 42.26(vii). □

Theorem 48.15 (What the word along a tree reads: inputs, group, work and price). *As stated.*

Proof. (i) Read the tree from the root. A part of the tree between the nodes of Σ, under the root or under a full child of a block, read on its shares, is the reading of Theorem 48.12(ii) of P_F or of the seam function of that child, the nodes of Σ directly below it taken as leaves read through their seam functions, the periods of their seam words, which are full: stacked Gammas of its shares, which are linear forms in the data and the shares above it, its node words kept or, opened on their monomials, powers of the coefficients of its seam letters, the seam words of its leaves, and the seam functions of the nodes of Σ below it at their loads. At a node read alone the fibre splits off as that of Theorem 48.12(i), the seam functions of its children converging; the nodes read jointly keep one fibre for each set, the seam function of a node that is not full diverging at every share. A node of Σ is, by Theorem 48.14(i), divided by the Gammas of its scaled shares and the powers of its constant parts, one integral over its scale quotient of $\boldsymbol{\xi}^{\mathbf{a}}$ times $e^{-\langle\boldsymbol{\xi},\mathbf{n}\rangle}\prod_P \mathcal{T}_P$. On a section of the scale

quotient by a monomial map, with the coordinates $\mathbf{y}$ that the word writes, the form $\boldsymbol{\xi}^{\mathbf{a}}\, d\boldsymbol{\xi}/\boldsymbol{\xi}$ of the quotient is a rational constant times $\mathbf{y}^{-\nu}\, d\mathbf{y}$ for an index ν linear in the shares, so the integral is that constant times the Trailmoment at the unit configuration $(\mathsf{T}_{\nu;I}[\mathbf{y}]\,\phi)\big((0,\infty)^r\big)$, $\mathsf{Z}_{\nu;I}(\mathbf{y}) = \mathbf{y}^{-\nu}$ (Definition 2.12), of the density $\phi = e^{-\langle \boldsymbol{\xi}, \mathbf{n}\rangle} \prod_P \mathcal{T}_P^{q_P}$ on the section, equal blocks having one transform; this density is its input, and it does not depend on the shares at which the node is read. The transform of a block whose children are full is the fibre integral of Theorem 48.14(ii), of Gammas, powers of the scales and of the coefficients of its readings and the seam functions of its children at loads linear in its shares, and the seam function of a child is read by its own word; another block with children is its exponential period, an integral over its orthant, over its quotient by the scaling when its node is not seen by its scales, into which the subtrees of its children enter whole; a block without children has a Gramma, a member of the serif family, as a factor of the input. A leaf outside Σ is a node with its seam word as its node word. The node words and seam words kept are, at lattice translates of their data, combinations with coefficients in $\mathbb{K}_{\mathbb{S}}$ of the values of the masters of their classes (Theorem 48.5(iii),(v), through Theorem 48.12(ii)). The classes of the Laurent insertions span the module of a class (Theorem 48.3(iii)), so a basis of masters can be taken among them, with $\langle \alpha^u \rangle(\boldsymbol{\nu}) = P_W(\boldsymbol{\nu} + (u; \mathbf{0}))$; $\mathrm{Sh}_{N\mathbf{d}_1}$ is a semilinear bijection, so it carries that basis to the basis of the $[\alpha^u f_{N\mathbf{d}_1}]$, whose walls are $\langle u, v\rangle + N\kappa_v(\mathbf{d}_1) \geq 0$, so that their values converge at every point of the tube $\mathcal{T}_1$ of the class (Lemma 48.2(iii)).

(ii) Every transform of a block, restricted to its section, generates a module of finite rank (Theorem 48.14(ii)), and so does an exponential of a constant part, of rank one, its derivatives along the section being multiples of it by Laurent polynomials. By Proposition 48.10(ii) the input of a node of Σ generates a submodule of a quotient of a construction from the sum of the modules of its distinct transforms and of its exponential, of finite rank; the sections of the nodes of one class being written in one set of coordinates, the sum of the modules of the distinct inputs on r scales is a subquotient of a construction from N_r, and by Proposition 48.10 its group is the image of G_{N_r} acting on its solutions. The group of the word is the product of these groups over r (Definition 48.9(ii)), a quotient of $\prod_r G_{N_r}$.

(iii) The work counts the distinct integrals of the word once each by their dimensions (Definition 33.2), Gammas and Grammas being functions of the word and not integrals in it: the fibre of every node read alone and the joint fibre of every set of nodes read jointly, with the shares inside the entries where a node word is opened; for every class of node words and seam words kept its masters, each an integral over V_{W_k} of the dimension $\dim V_{W_k}$, convergent by (i); the Trailmoment of every input, of the dimension of its section, the Trailmoments of one input being one integral read at other indices; the fibre of the transform of every block with full children; and the orthant of every other block with children, less one dimension when its node is not seen by its scales. Equal blocks give one transform to a power, a power not being an integral, and a node read alone, a node word, a leaf, a transform or an input that recurs in the tree is one integral read at other data, counted once; the shares of a node read jointly are coordinates of the joint fibre of its set, once for each occurrence.

(iv) The price counts the bits of the description, each part written once and referred to by an index wherever it recurs, the sections and the pins with it, and every power by the $\lceil \log_2(q+1) \rceil$ bits of its exponent (Definition 33.2).

(v) The word of (i) is composed of the share readings of Theorem 48.12(ii) on the parts of the tree read on their shares, of the scale readings of Theorem 48.14(i) at the nodes of Σ, which hold at complex shares whose real parts are shares at which their left sides are finite, and of the transforms of the blocks, exponential periods that converge absolutely on the tubes of their domains (Lemma 48.8(i)), those with full children read by the share readings of Theorem 48.14(ii). These

hold at complex data as (i) there does: on the contour through real shares at which they hold at the real parts, the pins moving it by a bounded imaginary translate, the Gammas $\Gamma(z_{LD\tau})$ decay exponentially in every imaginary direction of the fibre, $|(\xi_{LD}c_\tau)^{-z}| = (\xi_{LD}c_\tau)^{-\operatorname{Re} z}$, and the seam functions of the children are bounded by their values at the real parts of their loads, so both sides converge absolutely and locally uniformly and are holomorphic in the data on the tube over the real data at which the left side of Theorem 48.14(i) is finite at some shares, a convex set, and they agree at its real points. At complex data as stated the shares of the word have real parts at which every piece converges at the real parts of the data. A transform, an input and a scale integral at complex data have integrands of modulus at most their values at the real parts, the scales and the readings being positive on their orthants, and the share readings converge absolutely at complex data (Theorem 48.12(iv)); a node of Σ inside a share fibre enters as its seam function, the scale integral divided by its Gammas, bounded by its value at the real parts. So every integral of the word converges absolutely and locally uniformly on the tube over the real data of Theorem 48.12, which is connected (proof of Theorem 48.12(iv)), and the word is holomorphic there, as is the period (Theorem 48.3(ii)); they agree at the real points by (i), so on the tube. At every point of the domain of a transform its derivatives span a module of finite rank (Lemma 48.8(ii)), so every input generates one, as in (ii); (ii)–(iv) are read off the word as they are at real data, the work and the price depending on the tree, the choices and the classes alone. □

Corollary 48.16 (The word along the canonical tree). *As stated.*

Proof. F_{m} is a family of two tables on one molecule, the marks of the connected table $\mathcal{B}$, on its balance wall with every proper wall positive and a native gauge (Proposition 42.26(i)); its active letters are K and $\Psi_{\theta\mathsf{m}}$, at the exponent k. The marks of every subtree cell of the canonical hinge tree but its hinge are a bunch of width one of $\mathcal{B}$, and of F_{m}, whose tables have the bases of $\mathcal{B}$; they are nested as the cells are (Proposition 21.3(i),(ii)), so they form a tree of nested bunches (Definition 48.11), the cells of at least two marks directly below a node being its children and the marks left in place its own marks. Every node is full: below the root its seam word is the family of the two hinge minors of its cell, whose period $\widehat{\mathsf{V}}_{\mathcal{A}}(k;\ell)$ converges (Proposition 42.26(iii)), and the root is the family. Take the normalization of Theorem 48.14(iii), in which the seam letters of every node below the root are the letters of the two hinge minors of its cell with its own weights, so that the entries of a node are the weights of the bases of its core, times the norms at the root. The weights are 1 at the series and parallel nodes and factor across the bunches, and the norms are 1 below the root, so by Theorem 48.14(iii) the series and parallel nodes are separable and seen by their scales, each with one scale y, their readings and constant parts are 1 below the root, and their parts are their cells, the marks left in place among them; equal subtrees have equal seam letters and data, so they are one class. The nodes of Σ, those of S and the classes below the root, are read on that one scale, so every input of the word lies on $(0,\infty)$, and their modules are summed over $\mathbb{C}(y)$ (Definition 48.9). Every other node is read on its shares with its node word opened on its monomials, the bases of its core at the root and of the two hinge minors of its core below it (Theorem 48.12(i)), which is Proposition 42.26(iii) at the root and (v) below it; a node of Σ is read by (vi) below the root and (vii) at the root (Theorem 48.14(iii)). This is the word of Theorem 45.34.

(i) By Theorem 48.15(i) its inputs are, at the nodes of Σ, the products of the transforms of their distinct cells to their multiplicities, the constant parts being 0 on the scaled stations; by Theorem 48.14(iii) these are the dual transforms of the cells below a parallel node and their transforms below a series node, g for a mark below the root, and $\mathsf{g}(\mathsf{m}_e y)$ or $\mathsf{g}(y/\mathsf{m}_e)$ for a mark at the root, the constant $M^{-k} = \prod_e \mathsf{m}_e^{-k}$ of a series root multiplying the integral; at a class of s

marks below the root, of either kind, the input is g^s. These are the inputs of Theorem 45.34(i), which writes M^{-k} as the factors m_e^{-k}, the section $\xi_K = M^{-1}$ having that constant coefficient. The other integrals of the word are fibre integrals over shares, no node word or seam word being kept, so these are all its inputs; every node is full, so every node read on its shares is read alone.

(ii) By Theorem 48.15(ii) the group is a quotient of G_{N_1}, N_1 the sum of the modules of the distinct transforms read on the one scale: of g, of its dilations at the root, a constant factor not changing a module, and of the transforms that the nodes of S read of the distinct cells, other than marks, directly below them, each counted once whatever the multiplicities, the two transforms of a cell below nodes of both kinds being both counted. In the canonical hinge tree no two series nodes and no two parallel nodes are adjacent (Theorem 23.16), so every such cell is rooted at a prime node or at a node of the other kind. With S empty the inputs are the g^s, s over the sizes of the classes below the root, and N_1 is the module of g, whose group is SL_2 and whose s-th power generates its Sym^s (Theorem 45.28(ii)); by Theorem 48.15(ii) the group of the word is the image of SL_2 acting on the sum of the Sym^s, whose kernel is $\{\pm 1\}$ when every s is even, -1 acting on Sym^s by $(-1)^s$, and 1 otherwise: SL_2 when some size is odd, PGL_2 when every size is even, trivial when there is no class below the root, of dimension at most three. This is Theorem 45.34(ii).

(iii) By Theorem 48.15(iii) the work is the sum of the dimensions of the fibres of the distinct nodes outside Σ, the nodes outside S that are not classes below the root, which are those of Proposition 42.26(ii) at the root, $2N_v - n_v - 1$, and of (v) below it, $2N_v - n_v - 2$, the latter $p-1$ at a series or parallel node with p cells counted with their multiplicities, its core having one basis in one hinge minor and p in the other; of one for each distinct input, the inputs being on one scale: one for each distinct size of class below the root, the classes of one size of either kind having the one input g^s, and one for each distinct node of S that is not a class below the root, its input being written through the transforms of the distinct subtrees below it; and of the dimensions of the fibres of the distinct transforms of the cells other than marks directly below the nodes of S, by Theorem 48.14(ii) the number of the monomials of the readings less the number of the pins, $2-1=1$, the cell being present at one station in each of the two scaled stations and having its scale pin, a cell read by nodes of both kinds bringing both of its transforms. The marks have Grammas, no node word is kept and no leaf read on its period. This is the count of Theorem 45.34(iii). With every series and parallel node in S the multiplicities enter only as powers, and a distinct subtree other than a mark brings at most two integrals besides the fibre of its root when that is a prime node: its input and one transform if it is rooted at a series or parallel node, which lies directly below no node of its own kind (Theorem 23.16), and its two transforms if it is rooted at a prime node; this is the bound there. □

Definition 48.17 (Paths; the direct image of a reading). As stated.

Proof. (i) The letter at the top is the seam letter of the top read at the seam points of its children, $\ell = \sum_{\mathbf{D}} \mathbf{N}_{S_0,L}(D;\mathbf{D}) \prod_i V_{LD_i}^{(S_i)}$, S_0 the top and D dropped at the root, where the letters of the stand-in core times the extreme excess sums of the pieces are the letters of the family (Definition 48.11(i) and its proof). Substituting the same expansion of the seam letter of every child that is not a leaf, at its station, down to the leaves, writes ℓ as the sum over its paths of the products of their factors, a vanishing entry contributing nothing; expanding the products writes it as the sum of the terms.

(iii) For $r \in \mathbb{K}_W$ read on $\mathbb{S}$ through the projection, $\sigma_{(\mu,\sigma)} r = \sigma_\mu r$. The shifts of $\mathfrak{J}$ are semilinear and compose, $\mathrm{Sh}_{(\mu,\sigma)} \mathrm{Sh}_{(\lambda,\tau)} = \mathrm{Sh}_{(\lambda+\mu,\tau+\sigma)}$, by the cocycles of the kernel and of the nodes (Theorem 48.5(i),(ii)), so $\mathrm{Sh}_{(\mu,\sigma)} \left(r \,\mathrm{Sh}_{(\lambda,\tau)}[1]^{\otimes}\right) = \sigma_\mu(r) \,\mathrm{Sh}_{(\lambda+\mu,\tau+\sigma)}[1]^{\otimes}$: the shifts map $\mathfrak{J}^\natural$ into itself, and onto it, $\mathrm{Sh}_{(-\mu,-\sigma)}$ being the inverse. The lattice is commutative, so $\mathrm{Sh}_{(\mu,\sigma)}(\mathrm{Sh}_{(\mathbf{0},\tau)} - 1)t = (\mathrm{Sh}_{(\mathbf{0},\tau)} - 1)\,\mathrm{Sh}_{(\mu,\sigma)}\, t$, and the fibre translations fix $\mathbb{K}_W$, so $r(\mathrm{Sh}_{(\mathbf{0},\tau)} - 1)t = (\mathrm{Sh}_{(\mathbf{0},\tau)} - 1)(rt)$ for

$r \in \mathbb{K}_W$. So $\mathfrak{F}$ is the set of the finite sums $\sum_k (\mathrm{Sh}_{(\mathbf{0},\sigma_k)} - 1) t_k$, $t_k \in \mathfrak{J}^\natural$, and the shifts map it onto itself. That the shifts, the classes and the fibre integral of (iv) are well defined is part of Theorem 48.18(ii). □

Theorem 48.18 (The module of a family from its nodes). *As stated.*

Proof. (i) Let π be a path of a letter ℓ of the table of L, and $c\alpha^{\mathbf{t}}$ a term of it. The lift raises w_ℓ by one and the share of the entry of π at the top by one, keeping the total $\sum_{\mathbf{D}} z = w_\ell$ of ℓ at the top. At every node S' below the top it raises by one the share of the entry of the parent of S' into the station $D_{S'}(\pi)$, and so the load of that station, and, when S' is not a leaf, the share of $E_{S'}(\pi)$ out of it, keeping the conservation there. It moves the data of every node by the data of the stride of the monomial of the term in its factor: the exponents of that monomial on the marks of the node, and one more on the share or the load of the factor, $(\mathbf{t}|_{Z_{S'}}; \mathbf{e}_{E_{S'}(\pi)})$ at a node word and $(\mathbf{t}|_{S'}; \mathbf{e}_{(L,D_{S'}(\pi))})$ at the seam word of a leaf, the masses of W being read on the marks of the nodes by the coordinate maps ι_k (proof of Theorem 48.12(ii)). The difference of two exponents of one letter lies in its space of directions, so the pins of directions are kept; the coordinates are integers; and the lift lies in $\mathbb{S}(\mathbb{Z})$. The kernel is the product, over the nodes that are not leaves and the stations of their seam letters, of the stacked Gammas $\prod_{\mathbf{D}} \Gamma(z_{S',LD\mathbf{D}})/\Gamma(a_{S',LD})$ (Theorem 48.12(ii)), and the lift raises by one exactly the share of the entry of π and the load of its station at every such node, so with $(x)_1 = x$ it moves the kernel by R_π (Theorem 48.5(i)). A path has a factor at every node of the reading, so, with ϕ_k the factor of π at the node k, $\alpha^{\mathbf{t}_k}$ the monomial of the term in it and $[f_\mu] = \mathrm{Sh}_\mu[1]$ (Theorem 48.3(iii)),

$$\mathrm{Sh}_{((\mathbf{t};\mathbf{e}_\ell),\tau_\pi)}[1]^{\otimes} = R_\pi \bigotimes_k \big[\alpha^{\mathbf{t}_k}/\phi_k\big].$$

The terms of π are the products of one monomial of each factor with the products of their coefficients, which are constants; so, by multilinearity,

$$\sum_{c\alpha^{\mathbf{t}}} c\,\mathrm{Sh}_{((\mathbf{t};\mathbf{e}_\ell),\tau_\pi)}[1]^{\otimes} = R_\pi \bigotimes_k \Big[\sum_{\mathbf{t}'} c_{\mathbf{t}'}\,\alpha^{\mathbf{t}'}/\phi_k\Big] = R_\pi\,[1]^{\otimes},$$

the inner sum over the monomials of ϕ_k with their coefficients being $\phi_k/\phi_k = 1$ in the insertions of the node, its letter identity (Theorem 48.3(iv)). For a node S' that is not a leaf and a station D' of it let $Q_{S'}(D')$ be the sum, over the choices of the entries and the stations at S' and below it that start from D', of the products of the shares of the entries over the loads of their stations at S' and at the nodes below it that are not leaves. Then $Q_{S'}(D') = \sum_{\mathbf{D}'} \big(z_{S',LD'\mathbf{D}'}/a_{S',LD'}\big) \prod_i Q_{S'_i}(D'_i)$, Q being 1 at a leaf, and from the leaves up $Q_{S'}(D') = \sum_{\mathbf{D}'} z_{S',LD'\mathbf{D}'}/a_{S',LD'} = 1$ by the conservation at D'; at the top the same sum is 1 by the total of ℓ. So $\sum_\pi R_\pi = 1$ in $\mathbb{Q}(\mathbb{S})$, and the first identity holds.

Let k_e be the node whose word has the mark e: the node S', the top included, with $e \in Z_{S'}$, or the leaf S' with $e \in S'$. In a term, t_e is the exponent of α_e in its monomial in the factor of π at k_e, so

$$\sum_{c\alpha^{\mathbf{t}}} c\,t_e\,\mathrm{Sh}_{((\mathbf{t};\mathbf{e}_\ell),\tau_\pi)}[1]^{\otimes} = R_\pi\big[R^{(k_e)}_{\phi_{k_e},e}\big] \otimes \bigotimes_{k\neq k_e} [1], \qquad R^{(k_e)}_{\phi,e} = \frac{\alpha_e \partial_{\alpha_e}\phi}{\phi} = \sum_{\mathbf{t}'} c_{\mathbf{t}'}\,t'_e\,\frac{\alpha^{\mathbf{t}'}}{\phi},$$

the occupation of e in the letter ϕ of the word of k_e. Group the paths of the letters ℓ of one active letter L by their factor at k_e, a letter E of that word: the entry of L at a station D' of a node S' that is not a leaf, or the seam letter of the leaf S' at D'. For a node S' below the

top, with the chain $S_0 \supsetneq S_1 \supsetneq \cdots \supsetneq S_r = S'$ of the nodes from the top S_0 down to it, and a station D' of S', let $\varphi_\ell(S', D')$ be w_ℓ times the sum, over the stations of $S_1, \dots, S_r$, with D' at S_r, and over the entries of ℓ at $S_0, \dots, S_{r-1}$ that join them, each from the station of S_j into a tuple of stations of the children of S_j whose coordinate at S_{j+1} is the station of S_{j+1}, of the products of the shares of these entries over the loads of their stations, the load at the top being w_ℓ. At a child S'' of the top $\varphi_\ell(S'', D'')$ is the sum of the shares of the entries of ℓ at the top into D'', and the sum over the letters ℓ of L of these is the load $a_{S'',LD''}$, by its definition. At a child S'_i of S', $\varphi_\ell(S'_i, D'') = \sum_{D'} \varphi_\ell(S', D') \sum z_{S',LD'\mathbf{D}'}/a_{S',LD'}$ over the $\mathbf{D}'$ with $D'_i = D''$. Below the top the ratios $z_{S',LD'\mathbf{D}'}/a_{S',LD'}$ depend on (L, D') alone and not on the letter ℓ, so $\sum_\ell \varphi_\ell$ satisfies the same recursion as each φ_ℓ: if $\sum_\ell \varphi_\ell(S', D') = a_{S',LD'}$ at every station D' of S', then $\sum_\ell \varphi_\ell(S'_i, D'') = \sum z_{S',LD'\mathbf{D}'}$ over the $(D', \mathbf{D}')$ with $D'_i = D''$, which is $a_{S'_i,LD''}$. So from the top down $\sum_\ell \varphi_\ell(S', D') = a_{S',LD'}$ at every station of every node below the top. A path of ℓ through the entry E of S' at D' consists of such a choice along the chain, of E, and of continuations below the stations that E gives the children of S' and below every child, off the chain, of a node of the chain above S', at the station that its entry gives it; the products of the shares over the loads along these continuations sum to the $Q = 1$, so

$$\sum_\ell w_\ell \sum_{\pi:\ \phi_{k_e}(\pi) = E} R_\pi = \sum_\ell \varphi_\ell(S', D') \, \frac{z_E}{a_{S',LD'}} = z_E;$$

at a leaf the paths through its letter at D' have, the continuations off the chain summing to 1 again, $\sum_\ell \varphi_\ell(S', D') = a_{S',LD'}$, the exponent of that letter there; and at the top those through an entry E of ℓ have $w_\ell \, z_E / w_\ell = z_E$, the continuations below the children of the top summing to 1. Every letter of the word of k_e is the factor at k_e of the paths of the letters of one active letter, so the second sum of the statement is $\sum_E z_E \big[R^{(k_e)}_{E,e}\big] \otimes \bigotimes_{k \neq k_e} [1]$ over the letters E of that word at their exponents z_E, and the left side of the identity is $\big[m_e - \sum_E z_E R^{(k_e)}_{E,e}\big] \otimes \bigotimes_{k \neq k_e} [1]$. Its first factor is the class of $c_e \cdot 1 = (c_e + \partial_{y_e})1$ in the module of the word of k_e at its data $\iota_{k_e}(\mathbf{d}, \mathbf{z})$, the mass of e being read identically: its mark relation, which is 0 (Theorem 48.3(ii),(iv)). Along a chain k_e is the node of the step of e and this is the computation of Theorem 48.7(v) before the integration.

(ii) *The lattice.* Let B be the marks of W, $\mathcal{E}$ at the root and S at a full node S. The letters of W are letters of tables on B: at the root the letters of F, and at S, up to the positive constants of the normalization, the letters $K_{j,(D)}$, for a letter K_j of F, and $\Psi_{j,(D)}$, for a letter Ψ_j, of the room children of the stations D of S, tables on S (Definition 28.1). Their marks form one molecule of the family of these tables, at the root by hypothesis and at S since it is full (Theorem 48.23(i)). Two marks $a \neq b$ linked by a circuit of one of these tables are exchanged in two of its bases (Lemma 7.7), so $\mathbf{e}_b - \mathbf{e}_a$ is, up to its sign, the difference of two exponents of each letter of that table in W, the exponents of its two letters being complementary in B, and along chains of linked marks these differences span $\mathbf{1}^\perp \cap \mathbb{Z}^B$. A point $(\mathbf{u}; \mathbf{a})$ of $\mathbb{D}_W(\mathbb{Z})$ less $\sum_\ell a_\ell$ times the data of the stride of one monomial of each letter is $(\mathbf{u}'; \mathbf{0})$ with $\mathbf{u}' \in \mathbf{1}^\perp \cap \mathbb{Z}^B$, by the balance. So the data of the strides of the monomials of the letters span $\mathbb{D}_W(\mathbb{Z})$, and every one of them is the image of the lift of a term (i), every monomial of a letter being the monomial of a term of one of its paths, the coefficients being positive.

A presentation of the module. Let Φ_W be the $\mathbb{K}_W$-space with the basis $(\langle\lambda\rangle)_{\lambda \in \mathbb{D}_W(\mathbb{Z})}$ and the shifts $\mathrm{Sh}_\mu(r\langle\lambda\rangle) = \sigma_\mu(r)\langle\lambda + \mu\rangle$, and $p : \Phi_W \to \mathfrak{M}_W$ the map $\langle\lambda\rangle \mapsto \mathrm{Sh}_\lambda[1] = [f_\lambda]$, which commutes with the shifts and is onto (Theorem 48.3(iii)). Its kernel is the $\mathbb{K}_W$-span of the shifts of the letter identities $\mathrm{LI}_\ell = \sum_{\mathbf{t}} c_{\ell,\mathbf{t}} \langle(\mathbf{t}; \mathbf{e}_\ell)\rangle - \langle\mathbf{0}\rangle$ and of the mark relations $\mathrm{MR}_e = m_e\langle\mathbf{0}\rangle - \sum_\ell w_\ell \sum_{\mathbf{t}} c_{\ell,\mathbf{t}} t_e \langle(\mathbf{t}; \mathbf{e}_\ell)\rangle$, the sums over the monomials $c_{\ell,\mathbf{t}}\alpha^{\mathbf{t}}$ of ℓ. Indeed the shift of LI_ℓ by λ maps

to $[f_\lambda(\ell/\ell-1)]=0$. Since $(c_e(\mathbf{d})+\partial_{y_e})f_\lambda = c_e(\mathbf{d}+\lambda)f_\lambda$ and $f_\lambda R_{\ell,e} = \sum_{\mathbf{t}} c_{\ell,\mathbf{t}} t_e f_{\lambda+(\mathbf{t};\mathbf{e}_\ell)}$, the shift of MR_e by λ maps to the class of $(c_e(\mathbf{d})+\partial_{y_e})f_\lambda$, which is 0, and these elements of $\mathbb{C}[X_W]\otimes\mathbb{K}_W$ span $\mathcal{L}_W$, the f_λ spanning the insertions. Conversely, if $\sum_\lambda r_\lambda f_\lambda = 0$ in $\mathbb{C}[X_W]\otimes\mathbb{K}_W$ then $\sum_\lambda r_\lambda\langle\lambda\rangle$ lies in the span of the shifts of the letter identities: these rewrite each $\langle\lambda\rangle$ as a combination of the $\langle(\mathbf{v};N\mathbf{1})\rangle$ at one level above all the levels that occur, the shift of LI_ℓ by λ raising the level of ℓ by one, and the $f_{(\mathbf{v};N\mathbf{1})} = \alpha^{\mathbf{v}}\prod_\ell \ell^{-N}$ with distinct $\mathbf{v}$ are linearly independent, distinct Laurent monomials being so. An element of Φ_W whose image in $\mathbb{C}[X_W]\otimes\mathbb{K}_W$ lies in $\mathcal{L}_W$ is therefore a combination of shifts of mark relations modulo the span of the shifts of the letter identities. So $\mathfrak{M}_W$ is Φ_W modulo the shifts of the LI_ℓ and of the MR_e.

The direct image. For $\lambda\in\mathbb{D}_W(\mathbb{Z})$ and two lifts,

$$\mathrm{Sh}_{(\lambda,\tau')}[1]^\otimes - \mathrm{Sh}_{(\lambda,\tau)}[1]^\otimes = (\mathrm{Sh}_{(\mathbf{0},\tau'-\tau)}-1)\,\mathrm{Sh}_{(\lambda,\tau)}[1]^\otimes \in \mathfrak{F},$$

so e_λ does not depend on the lift, which exists. Likewise $\mathrm{Sh}_{(\lambda,\tau')}\,t - \mathrm{Sh}_{(\lambda,\tau)}\,t \in \mathfrak{F}$ for $t\in\mathfrak{J}^\natural$, and the shifts map $\mathfrak{F}$ onto itself (proof of Definition 48.17), so the shifts of $\mathfrak{H}$ are well defined, σ_λ-semilinear over $\mathbb{K}_W$, with $\mathrm{Sh}_\lambda\,\mathrm{Sh}_\mu = \mathrm{Sh}_{\lambda+\mu}$ and $\mathrm{Sh}_\mu\,e_\lambda = e_{\lambda+\mu}$. The classes e_λ span $\mathfrak{H}$, the image of $\mathfrak{J}^\natural$. The map $\tilde{O}:\Phi_W\to\mathfrak{H}$, $\langle\lambda\rangle\mapsto e_\lambda$, is $\mathbb{K}_W$-linear, onto, and commutes with the shifts. The coefficient $c_{\ell,\mathbf{t}}$ of a monomial of ℓ is the sum of the coefficients c of the terms of the paths of ℓ with that monomial, whose lifts are lifts of $(\mathbf{t};\mathbf{e}_\ell)$; so $\tilde{O}(\mathrm{LI}_\ell)$ and $\tilde{O}(\mathrm{MR}_e)$ are the classes of the differences of the two sides of the identities of (i), and vanish. $\tilde{O}$ commutes with the shifts, so it vanishes on the shifts of the letter identities and of the mark relations, and it factors through p: O is a well-defined map of $\mathfrak{M}_W$ onto $\mathfrak{H}$ that commutes with the shifts.

The fibre integral. Let $t=\sum_j r_j\,\mathrm{Sh}_{(\lambda_j,\tau_j)}[1]^\otimes\in\mathfrak{J}^\natural$ have the value 0 on $\mathbb{S}$, as when $t=0$ in $\mathfrak{J}$, the value being well defined on $\mathfrak{J}$ (Theorem 48.5(ii)). At a real $\mathbf{d}$ off the poles of the r_j with a point $\mathbf{c}$ admissible at $\mathbf{d}$ whose translates by the τ_j are admissible at the $\mathbf{d}+\lambda_j$, $P_W(\mathbf{d}+\lambda_j)$ is the absolutely convergent fibre integral of the value of $\mathrm{Sh}_{(\lambda_j,\tau_j)}[1]^\otimes$ through $\mathbf{c}$ (Theorem 48.5(iii)), so $\sum_j r_j(\mathbf{d})P_W(\mathbf{d}+\lambda_j)$ is the fibre integral of the value of t, which is 0. These pairs $(\mathbf{d},\mathbf{c})$ are cut out of $\mathbb{S}(\mathbb{R})$ by finitely many strict linear inequalities, so the $\mathbf{d}$ form an open set of real points, which is not empty (Theorem 48.5(iii)) and stays so off the poles of the r_j, a proper algebraic subset; the meromorphic function $\sum_j r_j P_W(\cdot+\lambda_j)$ vanishes there, so it vanishes on $\mathbb{D}_W$. So the fibre integral is well defined on $\mathfrak{J}^\natural$ and depends only on the value of the integrand. It vanishes on $\mathfrak{F}$, $(\mathrm{Sh}_{(\mathbf{0},\sigma)}-1)\,\mathrm{Sh}_{(\lambda,\tau)}[1]^\otimes$ integrating to $P_W(\cdot+\lambda)-P_W(\cdot+\lambda)$, and so it is well defined on $\mathfrak{H}$. Sh_μ carries $\sum_j r_j e_{\lambda_j}$ to $\sum_j \sigma_\mu(r_j)e_{\lambda_j+\mu}$, whose fibre integral is $\sum_j\sigma_\mu(r_j)P_W(\cdot+\lambda_j+\mu) = \sigma_\mu\big(\sum_j r_j P_W(\cdot+\lambda_j)\big)$; so $\int\mathrm{Sh}_\mu\,h=\sigma_\mu\int h$, and the elements of value zero of $\mathfrak{H}$ form a submodule. For $m=\sum_\lambda r_\lambda\,\mathrm{Sh}_\lambda[1]$, $\int O(m)=\sum_\lambda r_\lambda P_W(\cdot+\lambda)=\langle m\rangle$ (Theorem 48.3(iii)). So $O(m)=0$ gives $\langle m\rangle=0$, and $\mathfrak{H}$ is a quotient of $\mathfrak{M}_W$. W is a family of positive letters, so $\mathrm{Ann}\langle\cdot\rangle=0$ (Proposition 47.15(iii)), O is injective, and $\dim_{\mathbb{K}_W}\mathfrak{H}=\mathfrak{m}_W$. The node words are families of positive letters too, so the same proposition makes the quotient of the module of a node by a submodule of elements of value zero the module itself.

(iii) *Quotients.* Let $\mathfrak{J}$ and $\mathfrak{J}'$ be the integrand modules with the modules $\mathfrak{V}_k$ and with their quotients $\mathfrak{V}_k/\mathfrak{N}_k$, $\langle\mathfrak{N}_k\rangle=0$. $\mathfrak{J}'$ is the quotient of $\mathfrak{J}$ by the sum $\tilde{\mathfrak{N}}$ of the images of the tensor products with one factor $\mathfrak{N}_k\otimes\mathbb{K}_\mathbb{S}$; the shifts map $\tilde{\mathfrak{N}}$ onto itself, the $\mathfrak{N}_k$ being submodules, and its elements have the value 0, one factor of each product having the value 0. The quotient map carries the shifts of $[1]^\otimes$ to those of $[1]^\otimes$, so it maps $\mathfrak{J}^\natural$ onto $\mathfrak{J}'^\natural$ and $\mathfrak{F}$ onto $\mathfrak{F}'$, and $\mathfrak{H}'=\mathfrak{J}^\natural/(\mathfrak{F}+\mathfrak{J}^\natural\cap\tilde{\mathfrak{N}})$, the quotient of $\mathfrak{H}$ by the image of $\mathfrak{J}^\natural\cap\tilde{\mathfrak{N}}$. That image is mapped onto itself by the shifts, and its elements have the fibre integral 0, the fibre integral depending only on the value of the integrand (proof of (ii)); the fibre integral of $\mathfrak{H}'$ is the one induced.

The tree of a node down to Σ. For $S \in \Sigma$ the members of the tree that lie properly inside no member of Σ properly inside S form a tree of nested bunches of F, in the normalization of the tree, whose members properly inside S form the tree of S down to Σ. In it a member of Σ nearest below S has no member properly inside it, so it is a leaf, its node word its seam word (Definition 48.11(ii)). Every other member Q properly inside S, and S, have the children they have in the tree: if a child C of Q lay properly inside a member Q' of Σ properly inside S, then Q and Q', which meet, are nested; $Q \subseteq Q'$ would put Q properly inside Q' or make it a member of Σ, and $Q' \subsetneq Q$ would put C properly inside a member properly inside Q, against its being a child. So their node words are unchanged. Definition 48.17 applies to this tree, and by (ii) the direct image of the reading of the seam word of S along it, with the modules of its nodes, is the quotient of the module of the seam word of S by the kernel of O, a submodule of elements of value zero; at the root the seam word is W_F (the gloss after Definition 48.11). From the leaves up, the leaves in Σ carry quotients of their modules by submodules of elements of value zero, the module presented by an accepted set among them ((iv)), so by the first statement $\mathfrak{H}_S$ is a further quotient by such a submodule. A bijection as in the statement carries the stations, the transfer tensors, the node words and the seam words of the leaves inside one member to those inside the other (Theorem 48.12(iii)), so the shares, the pins and the kernel of its reading; by induction from the leaves up it carries the modules of the leaves in Σ, and then $\mathfrak{J}$, $\mathfrak{J}^\natural$, $\mathfrak{F}$ and $\mathfrak{H}$ (Theorem 48.5(v)). With Σ the full nodes, the tree of S down to Σ consists of the full nodes nearest below S, its leaves in Σ, and of the nodes that are not full, lie properly inside S and lie inside no full node properly inside S, the leaves of the tree that are not full among them; these are read in one fibre, as the nodes read jointly in Theorem 48.15. With $\Sigma = \{\mathcal{E}\}$ the tree of the root down to Σ is the tree. These submodules of elements of value zero are 0, the seam words and W_F being families of positive letters (Proposition 47.15(iii)), so $\mathfrak{H}_S$ is the module of the seam word of S and $\mathfrak{H}_\mathcal{E}$ is $\mathfrak{M}_{W_F}$.

(iv) *Spanning.* By (ii) the class of the left side of a certificate is $e_{\lambda+\mu} - \sum_{\lambda'} r_{\lambda'}^{\mu,\lambda} e_{\lambda'}$, and the right side lies in $\mathfrak{F}$, so $\mathrm{Sh}_\mu e_\lambda = e_{\lambda+\mu} = \sum_{\lambda'} r_{\lambda'}^{\mu,\lambda} e_{\lambda'}$. The span of the e_λ, $\lambda \in \Lambda$, contains $e_{\mathbf{0}}$, the class of $[1]^\otimes$, and is mapped into itself by the shifts by $\mathcal{G}$, which are σ_μ-semilinear, and so by every shift, every point of $\mathbb{D}_W(\mathbb{Z})$ being a sum of elements of $\mathcal{G}$; it contains every $e_\lambda = \mathrm{Sh}_\lambda e_{\mathbf{0}}$, so it is $\mathfrak{H}$. The fibre integral of $\mathrm{Sh}_\mu e_\lambda = \sum_{\lambda'} r_{\lambda'}^{\mu,\lambda} e_{\lambda'}$ is the relation among the values (ii).

The module presented. On $\mathbb{K}_W^\Lambda$ the maps Sh_μ are σ_μ-semilinear, and $\mathfrak{N}$ is the union of the increasing chain $\mathfrak{N}_0 \subseteq \mathfrak{N}_1 \subseteq \cdots$, $\mathfrak{N}_0$ spanned by the listed elements and $\mathfrak{N}_{i+1} = \mathfrak{N}_i + \sum_{\mu\in\mathcal{G}} \mathrm{Sh}_\mu \mathfrak{N}_i$, each a $\mathbb{K}_W$-subspace of a space of the dimension $|\Lambda|$, so the chain stops after at most $|\Lambda|$ steps, each step an elimination. On $\widehat{\mathfrak{H}} = \mathbb{K}_W^\Lambda/\mathfrak{N}$ the maps induced by Sh_μ are well defined; for $q \in \mathbb{K}_W$, $\mathrm{Sh}_\mu \mathrm{Sh}_\nu(q\varepsilon_\lambda) - \mathrm{Sh}_\nu \mathrm{Sh}_\mu(q\varepsilon_\lambda) = \sigma_{\mu+\nu}(q)\big(\mathrm{Sh}_\mu \mathrm{Sh}_\nu \varepsilon_\lambda - \mathrm{Sh}_\nu \mathrm{Sh}_\mu \varepsilon_\lambda\big)$, and likewise for $\mathrm{Sh}_{-\mu}\mathrm{Sh}_\mu$, so the induced maps commute and $\mathrm{Sh}_{-\mu}$ inverts Sh_μ. $\mathcal{G}$ being a basis of $\mathbb{D}_W(\mathbb{Z})$ and its negatives, the free commutative group on the basis is $\mathbb{D}_W(\mathbb{Z})$, which so acts on $\widehat{\mathfrak{H}}$ by semilinear maps, and $\rho(\lambda)$ modulo $\mathfrak{N}$ is $\mathrm{Sh}_\lambda \varepsilon_{\mathbf{0}}$. The subspace $\mathfrak{N}$ does not depend on the paths: the smallest subspace $\mathfrak{N}''$ carried into itself by the maps and containing the commutators and the inverses at the ε_λ contains them at every vector, by semilinearity, so on $\mathbb{K}_W^\Lambda/\mathfrak{N}''$ the induced maps commute and invert one another, and two paths from $\mathbf{0}$ to λ carry $\varepsilon_{\mathbf{0}}$ to vectors whose difference lies in $\mathfrak{N}'' \subseteq \mathfrak{N}$; so the listed elements of one choice of paths lie in the $\mathfrak{N}$ of another. $\widehat{\mathfrak{H}}$ is spanned by the classes of the $\varepsilon_\lambda = \rho(\lambda)$, so a basis of it among them gives masters, with the shift matrices of the induced maps. The map $\Phi_W \to \widehat{\mathfrak{H}}$, $\langle\lambda\rangle \mapsto \mathrm{Sh}_\lambda \varepsilon_{\mathbf{0}}$, commutes with the shifts and carries LI_ℓ and MR_e to the classes of their images under ρ, which lie in $\mathfrak{N}$, so it carries their shifts into $\mathfrak{N}$; by the presentation of (ii) it induces a map of $\mathfrak{M}_W$ onto $\widehat{\mathfrak{H}}$ that commutes with the shifts. The map $\mathbb{K}_W^\Lambda \to \mathfrak{H}$, $\varepsilon_\lambda \mapsto e_\lambda$, carries Sh_μ to the shift of $\mathfrak{H}$, by the certificates; its kernel is mapped into itself by the Sh_μ and contains

the listed elements, the shifts of $\mathfrak{H}$ commuting and composing, $\rho(\lambda)$ going to $\mathrm{Sh}_\lambda e_{\mathbf{0}} = e_\lambda$, and the images of the letter identities and the mark relations going to $\tilde{O}(\mathrm{LI}_\ell) = 0$ and $\tilde{O}(\mathrm{MR}_e) = 0$ (proof of (ii)); so it contains $\mathfrak{N}$, and $\widehat{\mathfrak{H}}$ maps onto $\mathfrak{H}$. The composite $\mathfrak{M}_W \to \widehat{\mathfrak{H}} \to \mathfrak{H}$ is O, so the kernel of $\mathfrak{M}_W \to \widehat{\mathfrak{H}}$ lies in that of O, of elements of value zero, which is 0 by (ii); so $\widehat{\mathfrak{H}}$ is $\mathfrak{M}_W$, its masters among the ε_λ being masters of $\mathfrak{M}_W$, and by the first statement of (iii) it may stand for $\mathfrak{H}$ there.

Existence and the search. $\mathfrak{H}$ is finite-dimensional and spanned by the e_λ (ii), so some finite $\Lambda \ni \mathbf{0}$ spans it; then for $\mu \in \mathcal{G}$ and $\lambda \in \Lambda$ there are $r_{\lambda'}^{\mu,\lambda}$ with $e_{\lambda+\mu} = \sum_{\lambda'} r_{\lambda'}^{\mu,\lambda} e_{\lambda'}$, so the left side of the certificate lies in $\mathfrak{F}$, a finite sum $\sum_k (\mathrm{Sh}_{(\mathbf{0},\sigma_k)} - 1) t_k$ (proof of Definition 48.17): a certificate. Write every t_k as a combination, with unknown coefficients in $\mathbb{K}_W$, of shifts of $[1]^\otimes$; a candidate is Λ with its lifts and, for every (μ, λ), finite sets of these shifts and of fibre translations. Every shift of $[1]^\otimes$ is a vector of $\mathfrak{J}$ over $\mathbb{K}_\mathbb{S}$ on the products of the masters of the modules of the nodes, $R_{\lambda,\tau}$ times the Kronecker product of the reductions of the $\mathrm{Sh}_{\iota_k(\lambda,\tau)}[1]$, which the shift matrices of the nodes at the generators of their lattices give along any path (Theorem 48.3(iii), the cocycle). In linear coordinates $(\mathbf{d}, \mathbf{u})$ on $\mathbb{S}$, $\mathbf{u}$ along the fibres, $\mathbb{K}_\mathbb{S} = \mathbb{K}_W(\mathbf{u})$; multiplied by a common denominator, the certificate is an identity of vectors of polynomials in $\mathbf{u}$ with coefficients in $\mathbb{K}_W$, linear in the unknowns, and comparing the coefficients of the monomials in $\mathbf{u}$ makes it a linear system over $\mathbb{K}_W$, decided by one elimination, over $\Bbbk(\mathbb{D}_W)$ when the masters of the nodes have their coefficients in $\Bbbk$ (Theorem 48.3(iii), the base change). The search reaches a certificate of an accepted set, which exists, and stops there.

(v) *The recursion.* $V_{LD}^S = \sum_{\mathbf{D}} \mathbf{N}_{S,L}(D; \mathbf{D}) \prod_i V_{LD_i}^{(S_i)}$ (Definition 48.11(i)), and by the multinomial theorem

$$\left(V_{LD}^S\right)^{A_{LD}} = \sum \frac{A_{LD}!}{\prod_{\mathbf{D}} \varepsilon_{LD\mathbf{D}}!} \prod_{\mathbf{D}} \mathbf{N}_{S,L}(D; \mathbf{D})^{\varepsilon_{LD\mathbf{D}}} \prod_i \left(V_{LD_i}^{(S_i)}\right)^{\varepsilon_{LD\mathbf{D}}},$$

the sum over the $\varepsilon_{LD\mathbf{D}} \in \mathbb{N}$ with the sum A_{LD}; the product over (L, D) collects the powers of the seam letters of each child at each of its stations into the loads $\mathbf{A}_i(\boldsymbol{\varepsilon})$. With $\alpha^{\mathbf{m}_S} = \alpha^{\mathbf{m}_{Z_S}} \prod_i \alpha^{\mathbf{m}_{S_i}}$ every term is the product of the Laurent polynomial $\alpha^{\mathbf{m}_{Z_S}} \prod \mathbf{N}^{\boldsymbol{\varepsilon}}$ in α_{Z_S} and of the $\alpha^{\mathbf{m}_{S_i}} \prod_{L,D'} (V_{LD'}^{(S_i)})^{A_{i,LD'}}$ in the α_{S_i}, in disjoint sets of variables, and its coefficient of $\alpha^{\mathbf{0}}$ is the product of theirs. At the root the letters of F are $L = \sum_{\mathbf{D}} \mathbf{N}_{\mathcal{E},L}(\mathbf{D}) \prod_i V_{LD_i}^{(S_i)}$, and on the balance hyperplane $\mathbb{D}_{W_F}$ the Laurent polynomial $\alpha^{\mathbf{m}} \prod_L L^{N_L}$, which is $\omega_{\mathbf{d}}/dy$, is homogeneous of the degree 0, a combination of the α^u with $u \in M_{W_F} = \mathbf{1}^\perp \cap \mathbb{Z}^{\mathcal{E}}$; so its coefficient of $\alpha^{\mathbf{0}}$ is its mean over the compact torus of X_{W_F}, the closing $\mathsf{C}(1)(\mathbf{d})$ of W_F (Theorem 48.23(ii)), which is its constant term on the chart $\alpha_{e_0} = 1$ (Definition 47.9).

The elements of value zero. The seam letters of a full node S are the letters $K_{j,(D)}$, for a letter K_j of F, and $\Psi_{j,(D)}$, for a letter Ψ_j, of the room children of its stations, tables on S (Definition 28.1), times the constants of the normalization, which multiply the weights; so its seam word at its shares is a family of letters of tables at the exponents a_{LD}, with the data space of Definition 48.1 and the closings C_S, and, being full, its marks form one molecule of the family of these tables (Theorem 48.23(i)). By Theorem 48.23(ii), Proposition 47.10 and Theorem 47.11 hold for it and for W_F, and for their quotients by submodules of elements of value zero, the closings being the constant terms on the compact tori of their letter complements; a full node of one mark has monomial letters, a point as its space V_W, the period $\prod c^{-w}$ of the coefficients and a module of dimension one with no nonzero element of value zero. For $x = \sum_\lambda r_\lambda f_\lambda$, $\mathsf{C}(x)(\mathbf{d}) = \sum_\lambda r_\lambda(\mathbf{d})\, \mathsf{C}(1)(\mathbf{d} + \lambda)$, $\mathsf{C}(1)$ being C_S. An element of $\mathfrak{H}_S$ is the image of an element of the module of the seam word with the same value ((iii)), so it has the value zero exactly when that element has; and by Proposition 47.15(iii) an element of value zero of these modules is 0. Bijections of subtrees as in (iii) carry the seam letters, the entries and the leaves, and so the closings. □

Definition 48.19 (The module of a transform; the twisted direct image of a block). As stated.

Proof. (i) Read at the seam points of the children, the seam letters of the node are $V^S_{LD} = \prod_l h_{lL} \prod_z \alpha_z^{u_{z,L}} \big(n_L(D) + \sum_P \widehat{\beta}_{P,LD}\big)$, the first product over the children of S, which is H_L for the one block (Definitions 48.11(i) and 48.13(i),(iii)), each $\widehat{\beta}_{P,LD}$ homogeneous of the degree δ_{LD} in the marks of its parts (proof of Theorem 48.14(ii)), so that $n_L(D) = 0$ when $\delta_{LD} \neq 0$. The transform reads the masses of the marks of the children, $m_z - \sum_L s_L u_{z,L}$ at the own marks and the exponents s_L of the H_L (Definition 48.13(iii)). When some mark of F lies outside B_P, as it does below the root and at a root read through at least two blocks, its mass takes the balance of F, and these data are all of $\mathbb{D}_P$. When S is the root and P its one block, B_P is every mark and V^S_L is the letter L of F, so the balance of F is $\sum_{e \in B_P} m_e = \sum_L w_L(\deg H_L + \delta_L)$ on the data of the block: the balance hyperplane of $\mathbb{D}_P$ when S is not seen by its scales, every δ_L being 0, and a hyperplane of $\mathbb{D}_P$ when it is seen and P has children; without children there are no w_L, and the exponents s_L take that balance when some $\delta_L \neq 0$.

(ii) The integrand of the transform at the data $\mathbf{d}_P$ is $\Omega\, dy$ with

$$\Omega = \alpha^{\mathbf{m}} \prod_L H_L^{-w_L} \exp\Big(- \sum \xi_{LD} \widehat{\beta}_{P,LD} \Big),$$

and $\omega_e = \partial_{y_e} \log \Omega$. Each $\widehat{\beta}_{P,LD}$ is H_L^{-1} times a Laurent monomial in the own marks times a polynomial with nonnegative coefficients in the marks of B_P, so this is the integrand of Lemma 48.8 with the h_k the H_L at the exponents w_L and the R_i the $\widehat{\beta}_{P,LD}$, and $\mathfrak{M}_P$ is the top cohomology H of the proof of that lemma, of finite dimension over $\mathbb{K}_P(\boldsymbol{\xi})$, the data and the scales taken as indeterminates. The maps D_i of that proof are the connections ∇_{LD}; they act on H and commute. The strides span $\mathbb{C}[Y_P] = \mathbb{C}[\alpha^{\pm 1}][(\prod_L H_L)^{-1}]$. The shift by λ multiplies Ω by f_λ and moves the data by λ, so it carries $(\partial_{y_e} + \omega_e)g \otimes r$ to $(\partial_{y_e} + \sigma_\lambda \omega_e)(f_\lambda g) \otimes \sigma_\lambda r$, $\sigma_\lambda \omega_e = \omega_e + \partial_{y_e} \log f_\lambda$, a relation; so the shifts are well defined, and they commute with the connections, σ_λ fixing the scales. A relation has the value 0 where its terms converge, by the integration by parts of that proof, and the value of f_λ at $\mathbf{d}_P$ is that of [1] at $\mathbf{d}_P + \lambda$ (part (i) there). On the quotient by the common scaling, part (iii) of the lemma reads the integral on a section, a torus of one dimension fewer, with an integrand of the same kind, invariant on the balance hyperplane, and the same holds there.

(iii), (iv) The share reading is that of Theorem 48.14(ii), whose proof does not use that the exponents of the absent letters are the s_L: at fixed seam points of the children the inner integral is the Gramma of the block, opened on its share side, and the powers of the seam coordinates are $\mathbf{x}_l^{-\mathbf{a}_l}$ at the loads of the definition, with w_L in the place of s_L. The maps ι_l carry $\mathbb{S}_P$ onto the data spaces of the seam words of the children: the present loads of a child at the stations of its seam word other than its absent ones are sums of disjoint nonempty sets of shares, each such station being that of some basis and so of some monomial of a seam letter of the node, its absent loads are the w_L less such sums, its masses are data of the block, and its scale pin is the balance of its data space (Definition 48.1(ii)). The kernel moves by Pochhammer quotients in the shares and by powers of the constants c_τ under the shifts, and the shifts of $\mathfrak{J}_P$ are those of Theorem 48.5(ii) for it. That the shifts, the connections and the scale integral are well defined on $\mathfrak{H}_P$ is part of Theorem 48.20(ii). □

Theorem 48.20 (The module of a transform from its block). *As stated.*

Proof. (i) *The lifts.* Let τ be a monomial of $\beta_{P,LD}$ and P_τ the set of the children present in it. A term of $c_\tau r_\tau$ is $c_\tau \prod_l c_{\mathbf{t}_l}\, \alpha^{\sum_l \mathbf{t}_l + \mathbf{q}_\tau - \mathbf{u}_L}/H_L$, the $c_{\mathbf{t}_l} \alpha^{\mathbf{t}_l}$ running over the monomials of $V^{(l)}_{LD_l(\tau)}$ for

$l \in P_\tau$ and of h_{lL} for the other children l of P, and $\mathbf{q}_\tau - \mathbf{u}_L$ the exponents of τ on the own marks; its stride is $\lambda = (\sum_l \mathbf{t}_l + \mathbf{q}_\tau - \mathbf{u}_L; \mathbf{e}_L)$. Move the share of τ by one. The pin of an own mark z moves by $q_{z,\tau} - u_{z,L}$ on both sides. A child S_l, $l \in P_\tau$, has its masses moved by $\mathbf{t}_l$ and its load at $D_l(\tau)$ raised by one, the share of τ entering it, and its absent load at L, w_L less the shares of the monomials of L in which it is present, unchanged; so its data move by $(\mathbf{t}_l; \mathbf{e}_{D_l(\tau)})$, the data of the stride $\alpha^{\mathbf{t}_l}/V^{(l)}_{LD_l(\tau)}$ of its seam word, which keeps its balance, $|\mathbf{t}_l|$ being the degree of that letter, and so its scale pin. A child of P absent from τ has its masses moved by $\mathbf{t}_l$, its absent load at L raised by one and its other loads unchanged: its data move by the stride $\alpha^{\mathbf{t}_l}/h_{lL}$ of its seam word. So $(\lambda, \mathbf{e}_\tau) \in \mathbb{S}_P(\mathbb{Z})$, the kernel moves by $\Gamma(z_\tau+1)c_\tau^{-z_\tau-1}/\big(\Gamma(z_\tau)c_\tau^{-z_\tau}\big) = z_\tau/c_\tau$, and

$$\mathrm{Sh}_{(\lambda,\mathbf{e}_\tau)}[1]^{\otimes} = \frac{z_\tau}{c_\tau} \bigotimes_{l\in P_\tau} \big[\alpha^{\mathbf{t}_l}/V^{(l)}_{LD_l(\tau)}\big] \otimes \bigotimes_{l\notin P_\tau} \big[\alpha^{\mathbf{t}_l}/h_{lL}\big].$$

Summing over the terms with their coefficients, each factor becomes $\big[V^{(l)}_{LD_l(\tau)}/V^{(l)}_{LD_l(\tau)}\big]$ or $[h_{lL}/h_{lL}]$, that is [1], by the letter identities of the children, and with $\boldsymbol{\xi}^{-Z(\mathbf{e}_\tau)} = \xi_{LD}^{-1}$ the sum is $\xi_{LD}^{-1} z_\tau [1]^{\otimes}$. A monomial $c_{\mathbf{t}}\alpha^{\mathbf{t}}$ of H_L, $\alpha^{\mathbf{t}} = \prod_l \alpha^{\mathbf{t}_l}$ with $\alpha^{\mathbf{t}_l}$ a monomial of h_{lL}, gives the stride $\alpha^{\mathbf{t}}/H_L$: with no share moved, the absent load of every child of P at L rises by one and its masses by $\mathbf{t}_l$, so its data move by the stride $\alpha^{\mathbf{t}_l}/h_{lL}$ of its seam word, the pins hold, the kernel does not move, and $\sum_{\mathbf{t}} c_{\mathbf{t}} \,\mathrm{Sh}_{((\mathbf{t};\mathbf{e}_L),\mathbf{0})}[1]^{\otimes} = \bigotimes_l [h_{lL}/h_{lL}] = [1]^{\otimes}$.

The mark relations. At an own mark z no H_L involves α_z, and $\alpha_z\partial_{\alpha_z} r_\tau = (q_{z,\tau} - u_{z,L})r_\tau$, so $(\partial_{y_z} + \omega_z)1 = m'_z - \sum_{L,D} \xi_{LD} \sum_\tau c_\tau (q_{z,\tau} - u_{z,L}) r_\tau$, whose lift is $\big(m'_z - \sum_\tau (q_{z,\tau} - u_{z,L}) z_\tau\big)[1]^{\otimes}$, the function in the bracket vanishing on $\mathbb{S}_P$ by the pin of z. At a mark e of a child S_l write $R^{(l)}_{LD',e} = \alpha_e\partial_{\alpha_e} V^{(l)}_{LD'}/V^{(l)}_{LD'}$ for the occupations of the letters of its seam word. Then $\alpha_e\partial_{\alpha_e} \log H_L = R^{(l)}_{LD^\circ_{l,L},e}$, and $\alpha_e\partial_{\alpha_e} r_\tau = r_\tau\big(R^{(l)}_{LD_l(\tau),e} - R^{(l)}_{LD^\circ_{l,L},e}\big)$ when $l \in P_\tau$ and 0 otherwise. Written over H_L, $w_L R^{(l)}_{LD^\circ,e} = w_L(\alpha_e\partial_{\alpha_e} h_{lL}) \prod_{l'\neq l} h_{l'L}/H_L$; lifted with $\mathbf{0}$ as the letter identity of H_L, the factor of S_l becomes $\big[R^{(l)}_{LD^\circ,e}\big]$ and the others [1]. Written over H_L, $c_\tau r_\tau R^{(l)}_{LD_l(\tau),e}$ is $c_\tau r_\tau$ with $V^{(l)}_{LD_l(\tau)}$ replaced by $\alpha_e\partial_{\alpha_e} V^{(l)}_{LD_l(\tau)}$ in the numerator; lifted with $\mathbf{e}_\tau$ as above, it gives $\xi_{LD}^{-1} z_\tau \big[R^{(l)}_{LD_l(\tau),e}\big]$ in the factor of S_l and [1] in the others. Written over H_L^2, $c_\tau r_\tau R^{(l)}_{LD^\circ,e}$ is c_τ times the numerator of r_τ times $(\alpha_e\partial_{\alpha_e} h_{lL}) \prod_{l'\neq l} h_{l'L}$, over H_L^2; lifted with $\mathbf{e}_\tau$, the share of τ rises by one and w_L by two, so every child present in τ has its load at its station and its absent load raised by one and every child of P absent from τ its absent load raised by two, and the lift is $\xi_{LD}^{-1} z_\tau \big[R^{(l)}_{LD^\circ,e}\big]$ in the factor of S_l and [1] in the others, by the letter identities. Summing, the lift of $(\partial_{y_e} + \omega_e)1$ is, in the factor of S_l,

$$\Big[m_e - \sum_L \Big(w_L - \sum_{\tau\ni l} z_\tau\Big) R^{(l)}_{LD^\circ_{l,L},e} - \sum_{L,D'} \Big(\sum_{\tau:\ D_l(\tau)=D'} z_\tau\Big) R^{(l)}_{LD',e}\Big] = \Big[m_e - \sum_{L,D} a_{l,LD}\, R^{(l)}_{LD,e}\Big],$$

the sums over the monomials τ of the readings of L in which S_l is present, a_l its loads: the defect $c_e^{(l)}$ of e in the seam word of S_l at its masses and loads (Definition 48.1(iv)), whose class is the mark relation of the child at e (Theorem 48.3(ii),(iii)), 0 in its module and in every quotient of it.

From a point of the lattice. Multiplying an insertion by f_λ moves the data of its strides by λ; lifting them with their share vectors plus τ_λ moves the data of every child by $\iota_l(\lambda, \tau_\lambda)$ more, where its letter identities and its mark relations hold, being identities among its insertions, and the kernel by the Pochhammer quotient R_{λ,τ_λ} more, the shares being moved by τ_λ. So the identities above, with the data moved by λ and the shares by τ_λ in their coefficients, hold for the shifts by (λ, τ_λ) of their terms, which is $\mathrm{Sh}_{(\lambda,\tau_\lambda)}$ applied to both sides; their coefficients are polynomials in the data, the shares and the scales.

(ii) *The lattice and* $\mathfrak{M}'_P$. By (i) the data of the terms of every $c_\tau r_\tau$, of every stride $\alpha^{\mathbf{t}}/H_L$ and of every term of a mark relation, written as there, lie in $\mathbb{D}'_P(\mathbb{Z})$. A connection carries $[f_\lambda \otimes r]$ to $[f_\lambda \otimes \partial r] - \sum_\tau c_\tau [r_\tau f_\lambda \otimes r]$, whose strides lie in $\lambda + \mathbb{D}'_P(\mathbb{Z})$; so $\mathfrak{M}'_P$ is carried into itself, and it contains the $\nabla^{\mathbf{a}}[1]$, the derivatives of [1].

A presentation of $\mathfrak{M}'_P$. As in the proof of Theorem 48.18(ii), the kernel of the map from the free module on $\mathbb{D}_P(\mathbb{Z})$ to $\mathbb{C}[Y_P]\otimes\mathbb{K}_P(\boldsymbol{\xi})$ is spanned by the letter identities $f_\lambda - \sum_{\mathbf{t}} c_{\mathbf{t}} f_{\lambda+(\mathbf{t};\mathbf{e}_L)}$ of the H_L, which raise the levels to a common one, at which the strides of distinct masses are independent; and $(\partial_{y_e} + \omega_e)f_\lambda$ is f_λ times ω_e at the data moved by λ, $\omega_e + \partial_{y_e}\log f_\lambda$, a combination of the strides at λ plus the data of the terms of (i). So the free module, the letter identities and the mark relations split along the cosets of $\mathbb{D}'_P(\mathbb{Z})$, the strides of distinct cosets being independent at a common level, and $\mathfrak{M}'_P$ is the free module on $\mathbb{D}'_P(\mathbb{Z})$ modulo the letter identities and the mark relations at its points, $\langle\lambda\rangle \mapsto \mathrm{Sh}_\lambda[1]$.

The twisted direct image. By (i), $z_\tau[1]^\otimes = \xi_{LD}\sum(\text{coefficient})\,\boldsymbol{\xi}^{-Z(\mathbf{e}_\tau)}\,\mathrm{Sh}_{(\lambda,\mathbf{e}_\tau)}[1]^\otimes$, and $z_\tau\,\mathrm{Sh}_{(\mu,\sigma)}[1]^\otimes = \mathrm{Sh}_{(\mu,\sigma)}\big((z_\tau - \sigma_\tau)[1]^\otimes\big)$, the shifts being semilinear; so $\mathfrak{J}^{\boldsymbol{\xi}}_P$ is carried into itself by the multiplications by the shares, by the derivatives of the coefficients and so by the connections, and by the shifts. For $t \in \mathfrak{J}^{\boldsymbol{\xi}}_P$ and a fibre translation $(\mathbf{0},\delta)$, the shift fixes $\boldsymbol{\xi}$ and moves the function Z_{LD} by $Z_{LD}(\delta)$, so

$$\nabla_{LD}\big(\boldsymbol{\xi}^{-Z(\delta)}\,\mathrm{Sh}_{(\mathbf{0},\delta)}\,t - t\big) = \boldsymbol{\xi}^{-Z(\delta)}\,\mathrm{Sh}_{(\mathbf{0},\delta)}(\nabla_{LD}t) - \nabla_{LD}t,$$

the derivative of $\boldsymbol{\xi}^{-Z(\delta)}$ cancelling the moved total; the connections and, the lattice being commutative, the shifts carry $\mathfrak{F}^{\boldsymbol{\xi}}_P$ into itself, and the same cancellation makes the connections commute with the shifts. The class of $\boldsymbol{\xi}^{-Z(\tau)}\,\mathrm{Sh}_{(\lambda,\tau)}\,t$ does not depend on the lift: two lifts differ by a fibre translation δ, and the difference is a twisted translation of the one. So the shifts, the classes and the connections of $\mathfrak{H}_P$ are well defined, the classes e_λ span it, the connections commute with one another and with the shifts, and on the classes, $\boldsymbol{\xi}^{-Z(\tau)}$ being differentiated,

$$\nabla_{LD}e_\lambda = -\Big[\boldsymbol{\xi}^{-Z(\tau)}\,\mathrm{Sh}_{(\lambda,\tau)}\,\big(\xi_{LD}^{-1}Z_{LD}[1]^\otimes\big)\Big].$$

The map O_P. On the free module on $\mathbb{D}'_P(\mathbb{Z})$, $\langle\lambda\rangle \mapsto e_\lambda$. By (i) from a lift of each point and the independence of the lifts, it carries the letter identities and the mark relations at every point of $\mathbb{D}'_P(\mathbb{Z})$ to 0, and by the presentation it induces O_P on $\mathfrak{M}'_P$, onto $\mathfrak{H}_P$; it commutes with the shifts, both sides being moved by σ_μ and the points by μ. $O_P(\widehat{\beta}_{P,LD}) = \sum_\tau c_\tau O_P(r_\tau) = \big[\xi_{LD}^{-1}Z_{LD}[1]^\otimes\big]$ by (i), so $O_P\big(\nabla_{LD}\,\mathrm{Sh}_\lambda[1]\big) = -\,\mathrm{Sh}_\lambda\,O_P(\widehat{\beta}_{P,LD}) = \nabla_{LD}e_\lambda$ by the display; with the derivatives of the coefficients, O_P commutes with the connections.

The scale integral. At real data $\mathbf{d}_P + \lambda$ with a contour of Theorem 48.14(ii), $\langle f_\lambda\rangle$ is the fibre integral of $\boldsymbol{\xi}^{-Z(\mathbf{z})}$ times the value of $[1]^\otimes$ at the shifted data, and moving the contour by the lift τ, it is the fibre integral at $\mathbf{d}_P$ of the value of $\boldsymbol{\xi}^{-Z(\mathbf{z})}\boldsymbol{\xi}^{-Z(\tau)}\,\mathrm{Sh}_{(\lambda,\tau)}[1]^\otimes$. The points $(\mathbf{d}_P,\mathbf{c})$ admissible for finitely many lifts are cut out of $\mathbb{S}_P(\mathbb{R})$ by strict linear inequalities, the shares and the loads having positive real parts and the masses and loads of the children lying in their tubes, and they exist along an admissible direction, as in Theorem 48.5(iii), the native split at a realization of Definition 48.17 being admissible (Theorem 48.14(ii)). So an element of $\mathfrak{J}^{\boldsymbol{\xi}}_P$ whose value vanishes has a vanishing scale integral on an open set of real data, and so on the connected part of the domain of Lemma 48.8(i) where its terms converge; a twisted translation integrates to 0, its two terms being one element of $\mathbb{D}'_P(\mathbb{Z})$ written with two lifts. So the scale integral is well defined on $\mathfrak{H}_P$, $\int O_P(m) = \langle m\rangle$, $\int \nabla_{LD}h = \partial_{\xi_{LD}}\int h$ by differentiation under the integral, dominated by the decay of the Gammas along the fibre, and $\int \mathrm{Sh}_\lambda\,h = \sigma_\lambda\int h$.

The rest. $O_P(m) = 0$ gives $\langle m\rangle = 0$, and $\dim\mathfrak{M}'_P \le \dim\mathfrak{M}_P$, finite (Lemma 48.8(ii)).

The values separate $\mathfrak{M}_P$. The relation at a mark e, written out, is $g \otimes m_e r - \sum_L \alpha_e \partial_{\alpha_e} (\log H_L)\, g \otimes w_L r - \sum_{(L,D)} \alpha_e \partial_{\alpha_e} \widehat{\beta}_{P,LD}\, g \otimes \xi_{LD} r + \partial_{y_e} g \otimes r$, m_e being m'_z at an own mark; so, as in Proposition 47.15(i), an element x of $\mathfrak{M}_P$ times a nonzero polynomial D in the data and the scales is the class of $\sum_k G_k \otimes p_k$, the $G_k \in \mathbb{C}[Y_P]$ linearly independent and the p_k polynomials in the exponents w_L and the scales. Let $\langle x \rangle = 0$. The domain of Lemma 48.8(i) is the set of the data whose real parts lie in an open convex cone, the same at all scales, and it is not empty, the value of [1] being $\mathcal{T}_P$ there; as in the proof of Proposition 47.15, the points of that cone far out along a ray of it lie in the domain of every stride of the G_k, so for $(\mathbf{w}, \boldsymbol{\xi})$ in a nonempty open set of real exponents and positive scales the masses at which every term converges have their real parts in a nonempty open set. Moving the masses there by imaginary vectors makes the value of $\sum_k G_k \otimes p_k$ the Fourier transform, on the space of the $y = \log \alpha$, its quotient by the common scaling when S is not seen by its scales, of $\sum_k p_k(\mathbf{w}, \boldsymbol{\xi})\, G_k$ times the integrand, an integrable function. So $\sum_k p_k(\mathbf{w}, \boldsymbol{\xi}) G_k$ vanishes on the orthant, and so on Y_P, a regular function on Y_P being a Laurent polynomial over a product of powers of the H_L, which are positive on the orthant; every p_k vanishes on an open set, $Dx = 0$, and $x = 0$. So O_P is injective, an isomorphism of $\mathfrak{M}'_P$ onto $\mathfrak{H}_P$. Over $\mathbb{E}_P$, when it is the hyperplane of the balance of F, the masses at fixed exponents lie on a hyperplane, which the argument does not reach, and (vii) tells the elements of value zero among the combinations of the derivatives of the input there.

(iii) The display of (ii) and $O_P(\widehat{\beta}_{P,LD}) = \sum_\tau c_\tau O_P(r_\tau)$, with $O_P(r_\tau)$ the combination of the classes of the terms of $c_\tau r_\tau$ divided by c_τ, give $\nabla_{LD} e_\lambda = -\operatorname{Sh}_\lambda O_P(\widehat{\beta}_{P,LD})$, a combination of classes of shifted points; on classes e_λ written on an accepted set the connection matrices are therefore read off the shift matrices along paths to these points, plus the derivatives of the coefficients. The proof of Theorem 48.18(iv) then holds verbatim over $\mathbb{K}_P(\boldsymbol{\xi})$: the spanning, the existence of accepted sets ($\mathfrak{H}_P$ being finite-dimensional and spanned by the classes), the certificates, identities in $\mathfrak{J}_P \otimes \mathbb{C}(\boldsymbol{\xi})$ over $\mathbb{K}_{\mathbb{S}_P}(\boldsymbol{\xi})$, made linear over $\mathbb{K}_P(\boldsymbol{\xi})$ by clearing denominators in the coordinates of the fibre and comparing coefficients, and the module presented, now by a subspace $\mathfrak{N}$ carried into itself by the shifts and by the connections read as $\partial_{\xi_{LD}} - \sum_\tau \operatorname{Sh}(\text{terms of } c_\tau r_\tau)$ and containing, besides the elements listed there, the images of the commutators of the connections with one another and with the shifts; the letter identities and the mark relations in its list are those of the H_L and of the transform, whose images are 0 by (i). The maps $\mathfrak{M}'_P \to \widehat{\mathfrak{H}} \to \mathfrak{H}_P$ commute with the shifts and the connections, by the same argument, and their composite is O_P; so the kernel of $\mathfrak{M}'_P \to \widehat{\mathfrak{H}}$ lies in that of O_P, which is 0 by (ii), and $\widehat{\mathfrak{H}}$ is $\mathfrak{M}'_P$.

(iv) *The objects over* $\mathbb{E}_P$. An element $\boldsymbol{\xi}^{-Z(\tau)} \operatorname{Sh}_{(\lambda,\tau)}[1]^\otimes$ is $\boldsymbol{\xi}^{-Z(\tau)}$ times $R_{\lambda,\tau}$, a rational function of the shares alone, the kernel depending on them alone, times the tensor product of the classes of the strides $\iota_l(\lambda, \tau)$ of the seam words of the children, with no coefficient to move; so it is defined over the share space over $\mathbb{E}_P$ once the ι_l carry that space onto the data spaces of the children, whose rational functions are then read there. They do. When $\mathbb{E}_P = \mathbb{D}_P$ this is the proof of Definition 48.19(iii). Otherwise, summing the pins of the block with the loads written in the shares, each monomial of a reading at L having the degree δ_L, gives $\sum_{e \in B_P} m_e = \sum_L w_L \deg H_L + \sum_L \delta_L Z_L$, so on $\mathbb{E}_P$ (proof of Definition 48.19(i)) the pins leave the one further condition $\sum_L \delta_L (w_L - Z_L) = 0$ on the shares and the w_L. The data of a child are free on the share space over $\mathbb{D}_P$, by the proof cited; and with its loads held, the condition is met by the share of a monomial of a reading of a letter with $\delta_L \neq 0$ in which the child is absent. Such a monomial exists: the absent station of the child is the station of a basis, whose monomial in $V_L^S = H_L \prod_z \alpha_z^{u_{z,L}} \big(n_L + \widehat{\beta}_{P,L}\big)$ is not in the constant part, n_L being 0 when $\delta_L \neq 0$, and some $\delta_L \neq 0$, S being seen by its scales.

The fibre translations fix the data, so they act on the rational functions of the share space over $\mathbb{E}_P$, and the twisted translations, the classes, their independence of the lifts and the connections

are defined as in (ii), with the same proofs; the identities of (i) from every point of $\mathbb{S}_P(\mathbb{Z})$ have coefficients polynomial in the data, the shares and the scales, so they hold there, and so does the presentation of $\mathfrak{M}'_P$, the mark relations at a point having coefficients polynomial in the data. The module of the transform over the rational functions of $\mathbb{E}_P$ and the scales is the top cohomology of the twisted de Rham complex with the data of $\mathbb{E}_P$ as indeterminates, finite-dimensional by the proof of Lemma 48.8(ii) over that field. So O_P is defined, onto $\mathfrak{H}_P$ and commutes with the connections, and the scale integral is defined, as in (ii), the native split at a realization of Definition 48.17, whose data lie in $\mathbb{E}_P$, being admissible and the admissible directions being taken in $\mathbb{E}_P$; the commutation with the shifts holds for the shifts by points of $\mathbb{E}_P$.

The derivatives. $\int \nabla^{\mathbf{a}} e_{\mathbf{0}} = \partial^{\mathbf{a}} \mathcal{T}_P$ on $\mathbb{E}_P$ by (ii), and $\mathfrak{H}^{\partial}_P$ is the span of the $\nabla^{\mathbf{a}} e_{\mathbf{0}}$, so its scale integral is the span of the derivatives of $\mathcal{T}_P$. Take a basis of $\mathfrak{H}^{\partial}_P$ among the $\nabla^{\mathbf{a}} e_{\mathbf{0}}$ containing $e_{\mathbf{0}}$, which is not 0, its scale integral $\mathcal{T}_P$ not being 0. The matrices of the connections on it have entries rational in the data and the scales, and off the common zeros of the coefficients of their denominators as polynomials in the scales, a proper algebraic subset of the data of F, they specialize. At such data the relations $\partial_{\xi_{LD}} \partial^{\mathbf{a}_i} \mathcal{T}_P = \sum_j A^{LD}_{ij} \partial^{\mathbf{a}_j} \mathcal{T}_P$ hold, holding on an open set of the data and the scales, both sides being holomorphic there; so the derivatives of $\mathcal{T}_P$ at these data lie in the span of the $\partial^{\mathbf{a}_i} \mathcal{T}_P$, and the module with the specialized matrices maps onto the module that $\mathcal{T}_P$ generates, the basis going to the $\partial^{\mathbf{a}_i} \mathcal{T}_P$. On a section of the scale quotient by a monomial map the restrictions of the derivatives span the derivatives of the restriction (proof of Theorem 48.14(ii)), and the same holds for the module read on the section: the sum of the mark relations of the transform, its Euler relation, is $\sum_{(L,D)\in\Sigma_S} \delta_{LD}\, \xi_{LD} \nabla_{LD} e_{\mathbf{0}} = -\big(\sum_{e\in B_P} m_e - \sum_L w_L \deg H_L\big) e_{\mathbf{0}}$, so the connection matrices on the basis are homogeneous for the scaling, their polar locus is a union of its orbits, and a section meets it in a proper subset.

The presentation by Λ. By the display of (ii) and (i) from the point (λ, τ_λ), $\nabla_{LD} e_\lambda = -\sum(\text{coefficient})\, e_{\lambda+\mu}$ over the terms of $\widehat{\beta}_{P,LD}$. Put $\nabla_{LD} \varepsilon_\lambda = -\sum(\text{coefficient})\, \rho(\lambda+\mu)$, $\rho(\lambda+\mu)$ the combination of the $\varepsilon_{\lambda'}$ that the certificate gives, and extend with the derivations of the coefficients. The map $\varepsilon_\lambda \mapsto e_\lambda$ commutes with these and the connections of $\mathfrak{H}_P$, by that formula and the certificates. The connections of $\mathfrak{H}_P$ commute; so the commutators of the connections on the vectors, which are linear over the rational functions, have values on the basis that map to 0, and the smallest subspace that the connections carry into itself and that contains these values maps to 0. On the quotient by it the connections commute, so it is a differential module, and it maps onto the span of the e_λ, $\lambda \in \Lambda$, which contains $\mathfrak{H}^{\partial}_P$, $\varepsilon_{\mathbf{0}}$ going to $e_{\mathbf{0}}$; so the submodule generated by $\varepsilon_{\mathbf{0}}$ maps onto $\mathfrak{H}^{\partial}_P$, and an element of the kernel has the scale integral 0. When $\mathbb{E}_P = \mathbb{D}_P$ the module presented is that of (iii), which is $\mathfrak{M}'_P$, and the map is the restriction of O_P, injective by (ii). $\mathfrak{H}_P$ has finite dimension and is spanned by the classes, so a finite $\Lambda \ni \mathbf{0}$ whose classes span it has certificates for all the $e_{\lambda+\mu}$, each class lying in the span and the difference of the two sides lying in $\mathfrak{F}^{\boldsymbol{\xi}}_P$, a finite sum of twisted translations; a search through the finite sets of points with lifts and of supports of certificates, in any order that reaches each, testing each by one elimination over the rational functions of the share space over $\mathbb{E}_P$ and the scales, stops. When $\mathbb{E}_P = \mathbb{D}_P$ every object here is that of (ii) and (iii).

(v) Without children, $\mathfrak{J}_P = \mathbb{K}_{\mathbb{S}_P}$, the pins are those of the own marks, $t\mathbf{z} = \mathbf{m}'_P$, and the transform is the Gramma of the block (Definition 48.13(iii)), read on its share side (Proposition 4.2) with the coefficients $\xi_{LD} c_\tau$. By (i), $c_\tau e_{t_\tau} = \xi^{-1}_{LD}[z_\tau]$, t_τ being the data of the insertion $r_\tau = \alpha^{t_\tau}$. The exchange relation of Theorem 2.4(ii) at the own mark z, $m'_z\, \mathsf{G} = \sum_\tau t_{\tau,z}\, \xi_{LD} c_\tau\, \mathsf{G}_{\mathbf{m}'+t_\tau}$, is in $\mathfrak{H}_P$ the identity $m'_z[1] = \sum_\tau t_{\tau,z}[z_\tau]$, the pin of z. The ladder, $\partial_{\xi_{LD}} \mathsf{G} = -\sum_\tau c_\tau \mathsf{G}_{\mathbf{m}'+t_\tau}$, is $\nabla_{LD} e_{\mathbf{0}} = -\big[\xi^{-1}_{LD} Z_{LD}\big] = -\sum_\tau c_\tau e_{t_\tau}$. For $\mathbf{v} \in \mathbb{Z}^N$ with $t\mathbf{v} = 0$, $\partial^{\mathbf{v}^\pm} \mathsf{G} = (-1)^{|\mathbf{v}^\pm|} \mathsf{G}_{\mathbf{m}'+t\mathbf{v}^\pm}$ by the ladder, the derivatives taken in the coefficients, so the toric relation is $\mathsf{G}_{\mathbf{m}'+t\mathbf{v}^+} = \mathsf{G}_{\mathbf{m}'+t\mathbf{v}^-}$,

one point of the lattice of the data written with the lifts $\mathbf{v}^+$ and $\mathbf{v}^-$, which differ by the fibre translation $\mathbf{v}$; in $\mathfrak{H}_P$ it is the independence of $e_{t\mathbf{v}^+}$ from the lift.

(vi) A bijection as stated carries the readings, the absent letters and their products, the shares, the pins, the kernel and the seam words of the children of one block to the other's, and by Theorem 48.18(iii) the modules of the children; so it carries $\mathfrak{M}_P$, $\mathfrak{J}_P$, $\mathfrak{J}_P^{\boldsymbol{\xi}}$, $\mathfrak{F}_P^{\boldsymbol{\xi}}$ and $\mathfrak{H}_P$, and the data read. By Proposition 48.10(ii) the input $e^{-\langle \boldsymbol{\xi},\mathbf{n}\rangle}\prod_P \mathcal{T}_P^{q_P}$ of a node of Σ generates a submodule of the image of $\bigotimes_P \operatorname{Sym}^{q_P}$ of the modules of its transforms, tensored with that of the exponential, of rank one; by (iv) each of these is the image of $\mathfrak{H}_P^{\partial}$, read at the data of F and restricted to the section, and so of the module presented by (iv). A sum of the images of modules is the image of their sum, so N_r is the image under the values of the sum of the modules presented by (iv) for the distinct blocks and of those of the exponentials, presented by their connection matrices, and its group is the image of the group of that module (Proposition 48.10).

(vii) *The display.* The proof of Theorem 48.14(i) holds with any exponents $\mathbf{a}$ of the scales. Integrating the exponentials of the readings and of the constant parts against $\boldsymbol{\xi}^{\mathbf{a}}\,d\boldsymbol{\xi}/\boldsymbol{\xi}$ gives $\prod_{\Sigma_S}\Gamma(a_{LD})(V_{LD}^S/A_L)^{-a_{LD}}$, read at the seam points. With the factors $A_L^{-s_L}$ of the transforms, the integrand becomes that of $W_S^\sharp$: A_L is the product of $H_L^S=\prod_l h_{lL}$ and the $\alpha_z^{u_{z,L}}$, at the exponent $s_L-\sum_{(L,D)\in\Sigma_S}a_{LD}=w_L$, the powers of the α_z going to the masses of the own marks. The common scaling multiplies it by e^{tc}, with c the imbalance of $W_S^\sharp$, which vanishes on its balance; so the integral over the scale quotient and the directions of S is its period there. On the pins of the seam the totals at the stations off Σ_S make up w_L, and the letters there are A_L times the constant parts, which is the left side of Theorem 48.14(i).

The section. Let the coordinates $\mathbf{y}$ be a basis of the monomials that the scaling keeps, so that $\mathbf{y}^{\mathbf{k}}=\boldsymbol{\xi}^{\mu_{\mathbf{k}}}$ with $\mu_{\mathbf{k}}$ integral and orthogonal to the degrees δ_{LD}. Then $\boldsymbol{\xi}^{\mathbf{a}}\,d\boldsymbol{\xi}/\boldsymbol{\xi}$ on the quotient is a nonzero constant times $\mathbf{y}^{\boldsymbol{\nu}(\mathbf{a})}\,d\mathbf{y}/\mathbf{y}$, the constant being 1 for a monomial section with the coefficients 1 and $C^{\mathbf{a}}$, fixed on the balance, for constant coefficients C; the index $\boldsymbol{\nu}(\mathbf{a})$ is linear in $\mathbf{a}$, and $\mathbf{y}^{\mathbf{k}}$ moves it by $\mathbf{k}$. The imbalance of $W_S^\sharp$ is its total mass less $\sum_{\Sigma_S}a_{LD}\deg V_{LD}^S+\sum_L w_L\deg H_L^S$, with $\deg V_{LD}^S=\deg H_L^S+\sum_z u_{z,L}+\delta_{LD}$; moving $\mathbf{a}$ by $\mu_{\mathbf{k}}$, $\mathbf{w}$ by minus its totals and every $m_z^\sharp$ by $\sum_L u_{z,L}T_L(\mu_{\mathbf{k}})$ changes it by $-\sum\mu_{\mathbf{k},LD}\delta_{LD}=0$; so this move is a point $\lambda_{\mathbf{k}}$ of its lattice.

The elements. The data of ϕ and $\mathbf{a}$ on the balance of $W_S^\sharp$ give its data through $w_L=s_L-\sum_D a_{LD}$ and $m_z^\sharp=m_z-\sum_L u_{z,L}w_L$, and every point of its data space comes so, with $s_L=w_L+\sum_D a_{LD}$ and $m_z=m_z^\sharp+\sum_L u_{z,L}w_L$; at a root not seen by its scales $\boldsymbol{\delta}=0$, and the balance of $W_S^\sharp$ is that of F, on which the data of ϕ lie. Move the data along a positive direction of $W_S^\sharp$ (Theorem 48.3(i)): for all large multiples every moved point of $E^\sharp$ lies in the tube of $W_S^\sharp$, as in Theorem 48.5(iii), and there, by the display, the Mellin transform of every $\mathbf{y}^{\mathbf{k}}\vartheta^{\mathbf{b}'}\phi$, $\mathbf{b}'\le\mathbf{b}$, converges absolutely on a common open set of indices: a ϑ brings down, under the transforms, a polynomial in the $\xi_{LD}\widehat{\beta}_{P,LD}$, whose moments in the scales are Gamma integrals of the same kind, converging where those of ϕ at the moved exponents do. In each coordinate $\int_0^\infty y^{\nu-1}y^k\vartheta^b G\,dy=(-\nu-k)^b\int_0^\infty y^{\nu+k-1}G\,dy$, by integration by parts, the boundary terms vanishing, an integrable function with an integrable derivative tending to 0 at both ends (proof of Lemma 48.8(ii)). So, by Fubini's theorem, the Mellin transform of E at $\boldsymbol{\nu}(\mathbf{a})$ is the constant of the section times $\prod\Gamma(a_{LD})\,\langle E^\sharp\rangle$, on an open set of the data of $W_S^\sharp$. With $\mathbf{y}=e^{\mathbf{v}}$ it is the Fourier transform, on a vertical plane, of the integrable function $E(e^{\mathbf{v}})e^{\langle \operatorname{Re}\boldsymbol{\nu},\mathbf{v}\rangle}$ of $\mathbf{v}\in\mathbb{R}^r$, which it determines. So E vanishes on an open set of its data, and so identically, exactly when $\langle E^\sharp\rangle$ vanishes on an open set of the data of $W_S^\sharp$, and so on all of them (Theorem 48.3(ii)).

The closings. The seam letters V_{LD}^S are the letters of the room children of the stations of S, tables on its marks, times the constants of the normalization (Definition 48.11). The absent

letter h_{lL} is the letter of the room child of the absent station of S_l, a table on S_l, and H_L^S is the letter, of the kind of L, of the direct sum of these tables over the children; on the marks of S the own marks are loops in it when L is a letter K_j, the bases avoiding them, and coloops when L is a letter Ψ_j, the bases containing them, so that its cobasis letter $\sum_T \theta_T \alpha^{S\setminus T}$ is the product of those of the children. So $W_S^\sharp$ is a family of letters of tables, and Theorem 48.23 applies to it, Proposition 47.12 with it; and an element of its module has the value zero exactly when it is 0 (Proposition 47.15(iii)). Below the root the masses of the marks of S and the exponents s_L are free in the data of F, the marks outside S taking up its balance; at a root not seen by its scales the data of ϕ are those of F; and at a root without children $W_S^\sharp$ has no letter H_L^S, and the data of F give the masses $m_z - \sum_L s_L u_{z,L}$ and $\mathbf{a}$ freely, as in the proof of Definition 48.19(i). In these cases the data of F and $\mathbf{a}$ reach all the data of $W_S^\sharp$. At a root seen by its scales with children the balance of F, $\sum_e m_e = \sum_L s_L(\deg A_L + \delta_L)$ with $\delta_L = 0$ off Σ_S, and that of $W_S^\sharp$ give $\sum_L \delta_L w_L = 0$ on the data reached.

The hyperplane. There the data of F and $\mathbf{a}$ reach every point of the hyperplane $\mathbb{E}_S^\sharp$ that this cuts out in the data of $W_S^\sharp$: a point of it gives $s_L = w_L + \sum_D a_{LD}$ and $m_z = m_z^\sharp + \sum_L u_{z,L} w_L$, which satisfy the balance of F exactly when $\sum_L \delta_L w_L = 0$. The letters of $W_S^\sharp$ other than the H_L^S with $\delta_L \neq 0$ include the letters $V_L^S = L$ of F at the L of Σ_S, and, at the other letters, at which no block is present and $V_L^S = n_L A_L$, the $H_L^S = n_L^{-1} \prod_z \alpha_z^{-u_{z,L}} L$; their differences of exponents are those of the letters of F, which generate those of one molecule, so these letters form a family of letters of tables with the one active molecule of $W_S^\sharp$ (Theorem 48.23(i)). The equation of $\mathbb{E}_S^\sharp$ involves the exponents of the H_L^S with $\delta_L \neq 0$ alone, so the points of Proposition 47.14(i) with these exponents 0, the others positive and the native gauge $(1, \dots, 1)$ lie in $\mathbb{E}_S^\sharp$. The real points of $\mathbb{D}_{W_S^\sharp}$ with these exponents 0, the others positive and every wall positive form an open cone in the real points of the rational subspace on which these exponents vanish, not empty since it contains those points; an integral point of it is a native direction $\mathbf{d}_1$ of $\mathbb{E}_S^\sharp$, and its native gauge, an isolated nondegenerate common zero on the orthant of the defects of $\mathbf{d}_1$, which are rational functions over the field of the weights, has coordinates algebraic over that field (Proposition 47.14(i)). When the weights are rational an integral multiple of the point with the native gauge $(1, \dots, 1)$ is such a $\mathbf{d}_1$, with that rational native gauge. The argument of *The elements*, with the data moved along $\mathbf{d}_1$, whose walls and whose exponents a_{LD}, $(L, D) \in \Sigma_S$, of the seam letters are positive, so that the Gamma integrals in the scales converge at the moved exponents, in the place of a positive direction, holds at each point of the data of F: E, read at the data of F, vanishes exactly when $\langle E^\sharp \rangle$ vanishes on an open subset of $\mathbb{E}_S^\sharp$, and so on $\mathbb{E}_S^\sharp$, which Proposition 47.14(iii), (iv) decides. The equation of $\mathbb{E}_S^\sharp$ involves the exponents alone, so $\mathbb{E}_S^\sharp$ consists of the data of $W_S^\sharp$ whose exponents lie on a hyperplane, with every mass that its data space allows at them, and it meets the tube of $W_S^\sharp$ at $\mathbf{d}_1$, whose walls are positive; so $\langle E^\sharp \rangle$ vanishes on $\mathbb{E}_S^\sharp$ exactly when $E^\sharp$ is 0 in the module of $W_S^\sharp$ on $\mathbb{E}_S^\sharp$ (Proposition 47.15(ii)). □

Proposition 48.21 (The question at every data). *As stated.*

Proof. (i) A letter with the exponent 0 does not enter the form, so the form is the master form $\alpha^{\mathbf{m}} \prod_\ell L_\ell^{-w_\ell}\, dy$ of the family W of positive letters formed by the letters L_ℓ of F at their exponents w_ℓ (Definition 48.1). Its space of directions is that of Theorem 48.23(i), the vectors of zero sum on every active molecule. So $\mathbf{m} - \sum_\ell w_\ell \mathbf{t}_\ell$ lies in it exactly when $m_M = \sum_\ell w_\ell |\mathbf{t}_\ell \cap M|$ for every active molecule M; an exponent of K_j meets M in $r_j(M)$ marks and one of Ψ_j in $|M| - r_j(M)$ (7.10), so this is $\kappa_M = 0$, the balance of M, the walls of M being $d_j(M) = r_j(M)$ and $d_j^*(M) = |M| - r_j(M)$.

With one active molecule this is the balance $\kappa_{\mathcal{E}} = 0$, so that $\mathbb{D}_W$ is the balance hyperplane in the masses and the exponents of the letters, and W is the family W_F of Definition 48.17.

(ii) The sum $|\alpha_{M_i}|$ is K of the table of rank one on $\mathcal{E}$ whose bases are the marks of M_i, with the weights 1, every other mark a loop; it links the marks of M_i and no others, so W^+ has the active molecules of F. The balance of M_i in W^+ is $\kappa_{M_i} - \kappa_{M_i} \cdot 1 = 0$, the new letter having the degree 1 on M_i and 0 elsewhere, so $(\mathbf{m}; \mathbf{s}, \mathbf{t}) \mapsto (\mathbf{m}; \mathbf{s}, \mathbf{t}, (\kappa_{M_i})_i)$ maps the data of F onto $\mathbb{D}_{W^+}$. On the orthant put $\alpha_{M_i} = \rho_i u_i$, $\rho_i = |\alpha_{M_i}|$, $u_i \in \Delta_{M_i}$, so that $\alpha_{M_i}^{\mathbf{m}_{M_i}-\mathbf{1}} d\alpha_{M_i} = \rho_i^{m_{M_i}-1} u_i^{\mathbf{m}_{M_i}-\mathbf{1}} d\rho_i \, d\omega_{M_i}(u_i)$ (2.7). Every basis of an active table meets M_i in $r_j(M_i)$ marks (7.10), so $K_j(\rho_1 u_1, \dots, \rho_q u_q) = \prod_i \rho_i^{r_j(M_i)} K_j(u)$ and $\Psi_j(\rho_1 u_1, \dots, \rho_q u_q) = \prod_i \rho_i^{|M_i| - r_j(M_i)} \Psi_j(u)$, whatever the weights; and $e^{-|\alpha|} = \prod_i e^{-\rho_i}$. The powers of ρ_i collect to $\rho_i^{\kappa_{M_i}-1}$, the walls of M_i being $d_j(M_i) = r_j(M_i)$ and $d_j^*(M_i) = |M_i| - r_j(M_i)$. At real data Tonelli gives $J_F = \prod_i \int_0^\infty \rho_i^{\kappa_{M_i}-1} e^{-\rho_i} d\rho_i$ times the integral over $\prod_i \Delta_{M_i}$, in $[0, \infty]$; the first factors are $\Gamma(\kappa_{M_i})$, finite for $\kappa_{M_i} > 0$, and the integral over the shapes is finite when the walls κ_U, U a nonempty proper subset of an active molecule, are positive, by the sector decomposition of the proof of 8.7 taken on every factor Δ_{M_i}, the sectors being the products of the sectors of the orders of the active molecules (Theorem 48.23(i)). At complex data the same holds with the moduli, and both sides continue meromorphically. The integrand of W^+, the form times $\prod_i |\alpha_{M_i}|^{-\kappa_{M_i}}$, is homogeneous of the degree 0 in the marks of every active molecule, so its integral on the charts $y_{e_i} = 0$ is its integral over $\prod_i \Delta_{M_i}$, where every $|\alpha_{M_i}|$ is 1 (8.7, one molecule at a time): that integral is P_{W^+}. For $q = 1$, P_{W^+} is the integral of the form over $\Delta_{\mathcal{E}}$, which is P_F at every data, and $J_F = \Gamma(\kappa_{\mathcal{E}}) P_F$ is 8.7.

(iii) The form is homogeneous of the degree $\kappa_{\mathcal{E}}$ under the common scaling, and a completion $\alpha^{-\kappa_{\mathcal{E}} w} \omega$ is projective (16.4); for $\kappa_{\mathcal{E}} \neq 0$ the form is not. By 16.8(ii) the data $(\lambda \mathbf{m}; \mathbf{s}, \mathbf{t})$ lie on the balance wall exactly when $\lambda \mathbf{m} = \boldsymbol{\tau}$, that is when $\lambda m_{\mathcal{E}} = \sum_j (s_j r_j + t_j r_j^*)$, the degree of the word; so λ is the displayed rational function. The pseudointegral is $\mathrm{CT}_{\eta=0} P_F(\boldsymbol{\tau} + \eta \mathbf{m}; \mathbf{s}, \mathbf{t})$ by 16.10, P_F being meromorphic in the masses with its poles on the hyperplanes $\kappa_S \in \{0, -1, \dots\}$, S proper; off them it is $P_F(\boldsymbol{\tau}; \mathbf{s}, \mathbf{t})$, which with a native gauge is a convergent integral (16.15) and otherwise its continuation (16.16). Off the balance wall P_F is the period of W^+ by (ii), so the constant term is that of the period of W^+ along the line $\boldsymbol{\tau} + \mathbb{C}\mathbf{m}$ of $\mathbb{D}_{W^+}$, the image of the ray of the masses. For $q \geq 2$, a union of active molecules has $c_j = 0$ in every active table (7.10), so every basis of table j meets M_i in the same number $r_{j,i}$ of marks; K_j is homogeneous of the degree $r_{j,i}$ and Ψ_j of the degree $r_{j,i}^*$ in the marks of M_i, whatever the weights, and the balance of M_i (Theorem 48.23(i)) is $m_{M_i} = \sum_j (s_j r_{j,i} + t_j r_{j,i}^*)$, which $\boldsymbol{\tau}$ satisfies. The data $\boldsymbol{\tau} + \sum_i \eta_i \mathbf{m}_{M_i}$ are data of F, so they give an affine subspace of $\mathbb{D}_{W^+}$ of the dimension q by (ii), on which the period of W^+ is meromorphic with its poles on the hyperplanes $\kappa_U \in \{0, -1, \dots\}$, U a nonempty proper subset of an active molecule (Theorem 48.3(ii) with Theorem 48.23(i)): the letter $|\alpha_{M_{i'}}|$ adds $\kappa_{M_{i'}} \min_{e \in M_{i'}} [e \in U] = 0$ to such a wall, so these walls are those of F. A wall κ_U with $U \subseteq M_i$ is linear and moves along that subspace by $\eta_i m_U$ alone, so near $\boldsymbol{\eta} = 0$ the period is a holomorphic function divided by a product of powers of the η_i, and its constant term, the coefficient of $\boldsymbol{\eta}^{\mathbf{0}}$ of its Laurent expansion, is the iterated constant term in any order. At $\boldsymbol{\eta} = 0$ every κ_{M_i} is 0, the letters $|\alpha_{M_i}|$ have the exponent 0, and the period of W^+ is that of W, the reduced period of (iv), when $\boldsymbol{\tau}$ lies on no pole hyperplane. With factoring weights the period of W^+ is the product of those of the molecules, the integrand and the product of simplices factoring (Proposition 7.9), each a function of its own η_i, so the constant term is the product of the constant terms, the pseudointegrals of the molecules at their targets (16.10).

(iv) A union S of active molecules has $c_j(S) = 0$ in every active table (7.10), so 8.16 gives $\kappa_S + \kappa_{\mathcal{E} \setminus S} = \kappa_{\mathcal{E}}$, which is 0 on the balance wall: one of the two walls has real part at most 0,

and the period, which converges only when every proper wall has positive real part (8.7), diverges, as does the integral of the form over the orthant along every ray of the common scaling. 16.17 gives the vanishing of P_F on the balance wall. The proof of 16.12 uses of the letters only that $K_j(\rho_1 u_1, \dots, \rho_q u_q) = \prod_i \rho_i^{r_j(M_i)} K_j(u)$ and $\Psi_j(\rho_1 u_1, \dots, \rho_q u_q) = \prod_i \rho_i^{|M_i| - r_j(M_i)} \Psi_j(u)$, which hold for every active table whatever its weights, every basis meeting M_i in $r_j(M_i)$ marks (7.10), and that the integral over the shapes is a smooth function of the imaginary imbalances: here $f(\boldsymbol{\eta}')$ is the integral over $\prod_i \Delta_{M_i}$ at the masses $\mathbf{m}_i^0 + i\eta_i w_i$ on the parts. That integral is holomorphic in the masses where every wall κ_U, U a nonempty proper subset of an active molecule, has positive real part, by the sector decomposition of the proof of 8.7 taken on every factor Δ_{M_i}, the sectors being the products of the sectors of the orders of the active molecules (Theorem 48.23(i)); and at $\mathbf{m}^0 + i\boldsymbol{\eta} w$ these walls have the real parts of those at $\mathbf{m}^0$, positive. So f is smooth. So its proof gives (i)–(iii) there, with $f(0) = P_{V_F}(\mathbf{m}^0; \mathbf{s}, \mathbf{t})$. On the data space of W the integrand is homogeneous of the degree 0 in the marks of every active molecule, so its integral over $\prod_i \Delta_{M_i}$ is its integral on the charts $y_{e_i} = 0$, one mark e_i in each active molecule (8.7, one molecule at a time), whose measure gives the lattice of V_W the covolume one: the value $\langle 1 \rangle$ of Definition 48.1(v). With factoring weights $K_j = \prod_i K_{j,i}$ and $\Psi_j = \prod_i \Psi_{j,i}$ (7.9), and the integral is the product.

(v) With every letter of every active table a letter this is 8.7 and 47.2; in general it is Lemma 48.2(iii) and Theorem 48.3(i), (ii), with the fan and the walls of Theorem 48.23(i). □

Definition 48.22 (A factorization of the weights; the molecule families). As stated.

Proof. A circuit of a direct sum is a circuit of one summand, a minimal dependent set being dependent in the summand that contains its intersection with some dependent part; so two marks are linked in an active table exactly when they are linked in its restriction to the active molecule that contains them, and the marks of M_i, one class of the equivalence generated by linking in the active tables, are one class of the equivalence generated by linking in the tables $\mathcal{B}_j|M_i$: one molecule of $F^{(i)}$. Expanding the products, $\sum_r \prod_i K_{j,r}^{(i)} = \sum_{T_1,\dots,T_q} \left(\sum_r \prod_i \theta_{j,r}^{(i)}(T_i) \right) \prod_i \alpha^{T_i} = \sum_T \theta_{j,T} \alpha^T = K_j$, the bases of table j being the unions $T_1 \sqcup \cdots \sqcup T_q$ (7.9), and likewise Ψ_j, with $\alpha^{\mathcal{E} \setminus T} = \prod_i \alpha^{M_i \setminus T_i}$. A factorization with one element in every R_j is a factoring $\theta_{j,T} = \prod_i \theta_j^{(i)}(T \cap M_i)$, and conversely. An active molecule $\{e\}$ of one mark is linked to no mark, so e is a loop or a coloop in every active table, the restrictions $\mathcal{B}_j|\{e\}$ have the one basis $\varnothing$ or $\{e\}$, and the letters of its molecule family are monomials; its space of directions is a point, and its module has the dimension one, as in the proof of Theorem 48.18(v). □

Theorem 48.23 (The closings for every family of letters of tables). *As stated.*

Proof. (i) Let e, e' be marks linked in an active table j. Some basis T has $e \in T$, $e' \notin T$ and $T' = (T \setminus \{e\}) \cup \{e'\}$ a basis (7.7), so $\mathbf{1}_T - \mathbf{1}_{T'} = \mathbf{e}_e - \mathbf{e}_{e'}$ is a difference of two exponents of K_j, and $\mathbf{1}_{\mathcal{E} \setminus T} - \mathbf{1}_{\mathcal{E} \setminus T'} = \mathbf{e}_{e'} - \mathbf{e}_e$ one of Ψ_j; whichever of them is in W puts $\mathbf{e}_e - \mathbf{e}_{e'}$ in the lattice generated by the differences. These vectors generate the integral vectors of zero sum on every active molecule, the active molecules being the classes of the equivalence generated by linking in the active tables. Conversely every difference of two exponents of a letter has zero sum on every active molecule, every basis of an active table meeting it in $r_j(M)$ marks (7.10). So the differences generate the integral vectors of zero sum on every active molecule, a saturated lattice, which is therefore $M_W = \vec{\mathcal{N}}_W \cap \mathbb{Z}^{\mathcal{E}}$, with $\vec{\mathcal{N}}_W$ the real vectors of zero sum on every active molecule. Its orthogonal is spanned by the indicators of the active molecules, and $\alpha^u = 1$ for every $u \in M_W$ exactly when $\alpha_e = \alpha_{e'}$ for marks e, e' of one active molecule.

For a tuple $\pi = (\pi_M)_M$ of orders of the active molecules let $C_\pi \subseteq V_W$ be the cone of the v whose coordinates do not increase along π_M on every M, a cone of the dimension r_W with the generators $\mathbf{1}_U$, U a head of some π_M, nonempty and proper in M, and $|\det| = 1$; these cones cover V_W with disjoint interiors. The bases of an active table are the unions of bases of its restrictions to its own molecules, each inside one active molecule (7.9), so on C_π the least value of $\langle \mathbf{1}_T, v\rangle$ over its bases, which moves by a constant when v moves by an indicator of an active molecule, is taken at the basis that the greedy rule builds from the marks of least coordinates, the same at every point of C_π, and the least value of $\langle \mathbf{1}_{\mathcal{E}\setminus T}, v\rangle$ at the basis that it builds from the marks of largest coordinates. So the cones form a fan of W (Lemma 48.2(i)), and the wall of $\mathbf{1}_U$ (Lemma 48.2(ii)) is m_U less the sum, over the letters, of the exponent times the least value of $\langle \mathbf{t}, \mathbf{1}_U\rangle$ over the exponents $\mathbf{t}$ of the letter, which is $d_j(U)$ for K_j and $d_j^*(U)$ for Ψ_j: the wall κ_U.

(ii) A line $\mathbf{d}_0 + \mathbb{C}\mathbf{d}_1$ of $\mathbb{D}_W$, $\mathbf{d}_0$ integral and $\mathbf{d}_1$ a positive direction, carries the ray with the stride $f = f_{\mathbf{d}_1}$ and the origin form $\omega_{\mathbf{d}_0}$, its insertions, its relation space and its module the restrictions of those of W (Definition 47.3, Proposition 47.5, read with Theorem 48.3(iii)); the unit $\omega_{\mathbf{d}_0}/dy$ carries it to the ray with the origin 0, as in the first paragraph of the proof of Theorem 39.57. The proof of Theorem 47.11 reduces it, ray by ray, to Theorem 39.57, and adds the density of the positive directions in the open cone of the real data with positive exponents and positive walls, which for W is Theorem 48.3(i). Theorem 39.57 rests on Proposition 39.34, Theorem 38.14(i) and Theorem 38.6(i), and its proof uses one molecule at two places; Theorem 44.16 rests on Theorem 39.57 and on the closings being a solution of the shift. Each holds for W:

The closings. For integral $\mathbf{d} \in \mathbb{D}_W$ and an insertion g such that $g\,\omega_{\mathbf{d}}/dy$ is a Laurent polynomial, a combination of the α^u, $u \in M_W$, the closing $\mathsf{C}(g)(\mathbf{d})$ is its coefficient of $\alpha^{\mathbf{0}}$, its mean over the compact torus of X_W. The constant term of ∂_{y_e} of a Laurent polynomial is 0, so $\mathsf{C}\big((c_e(\mathbf{d}) + \partial_{y_e})g\big)(\mathbf{d}) = 0$, and $\mathsf{C}(f_\lambda g)(\mathbf{d}) = \mathsf{C}(g)(\mathbf{d}+\lambda)$: the proof of Proposition 47.10 holds as it stands, its use of Proposition 39.35(ii) at $j = 0$ being covered by the next paragraph.

The pencil. For a positive direction $\mathbf{d}_1$ the stride $f = f_{\mathbf{d}_1}$ is positive on the orthant, $\log f(e^y) = \langle \mathbf{m}_1, y\rangle - \sum_\ell w_{1,\ell} \log L_\ell(e^y)$, and the Hessian of $\log L_\ell(e^y)$ is the covariance of the exponent under the law proportional to $c_{\ell,\mathbf{t}} e^{\langle \mathbf{t}, y\rangle}$ on the support of L_ℓ (7.16), every exponent having positive weight at a real point. A direction u' in the kernel of the Hessian of $\log f$ has $\langle u', \mathbf{t} - \mathbf{t}'\rangle = 0$ for any two exponents of every letter, $w_{1,\ell} \geq 1$, so $u' \in \vec{\mathcal{N}}_W^\perp$ by (i), which is 0 in V_W: $\log f$ is strictly concave on V_W. On every cone of the fan of (i), $f = \prod_k q_k^{\kappa_{v_k}(\mathbf{d}_1)} \prod_\ell k_{\ell,\pi}(q)^{-w_{1,\ell}}$ with $k_{\ell,\pi}$ at least its constant term, which is positive (Lemma 48.2(iii)), and every $\kappa_{v_k}(\mathbf{d}_1) > 0$; so $f \leq C' e^{-c'\|y\|}$ on V_W, f has one largest point, the native gauge $\alpha^\star$ of the direction, and it is nondegenerate. This is Theorem 38.14(i) for W, and Theorem 38.6(i), the expansion at a nondegenerate largest point with the rest of V_W contributing $O((f^\star - \delta)^k)$, holds for W with r_W in the place of $n-1$.

The top principal parts. In the proof of Proposition 39.34 the sector formula is replaced by the cone formula of Lemma 48.2(iii) for the fan of (i), whose terms 8.4 continues; for a monomial α^u, $u \in M_W \setminus \{0\}$, a mark e with $u_e \neq 0$ and the relation of Theorem 48.3(ii) at the data $\epsilon \mathbf{d}_1$ give $u_e \langle \alpha^u\rangle_\epsilon = -\epsilon \langle c_e^{(1)} \alpha^u\rangle_\epsilon$; and $\epsilon^{r_W} \langle 1\rangle_\epsilon \to V_1$ as $\epsilon \downarrow 0$ by the cone formula at $\epsilon\mathbf{d}_1$, every $k_{\ell,\pi}(q)^{-\epsilon w_{1,\ell}}$ tending to 1 boundedly and $\int_0^1 q^{\epsilon\kappa - 1} dq = 1/(\epsilon\kappa)$, with $V_1 = \sum_\pi \prod_k \kappa_{1,U_{\pi,k}}^{-1}$ over the tuples of orders, the product over the active molecules of their sums. The proof of Proposition 39.35(ii) uses the same cone formula and the same relations, and holds for W with these replacements.

The torus. On the torus of X_W through $\alpha^\star$, $|L_\ell(\alpha^\star e^{i\theta})| \leq L_\ell(\alpha^\star)$, the coefficients being positive, with equality only when $\langle \theta, \mathbf{t} - \mathbf{t}'\rangle \in 2\pi\mathbb{Z}$ for any two exponents of L_ℓ; for all the letters this says, by (i), that θ is constant modulo 2π on every active molecule, which is the identity of the torus of X_W. So $|f^{-1}(\alpha^\star e^{i\theta})| < 1/f^\star$ off a neighbourhood of the identity, and the expansion of the closings in the proof of Theorem 39.57 holds, its Gaussian moments taken on V_W.

With these, the proofs of Theorems 39.57, 44.16 and 47.11 hold for W as written, with r_W in the place of $n-1$. The generators of Theorem 48.3(iv) and their negatives are a basis of $\mathbb{D}_W(\mathbb{Z})$ and its negatives, $(u;\mathbf{a}) - \sum_\ell a_\ell(\mathbf{t}_\ell;\mathbf{e}_\ell)$ being $(u - \sum_\ell a_\ell\mathbf{t}_\ell;\mathbf{0})$ with $u - \sum_\ell a_\ell\mathbf{t}_\ell \in M_W$, and the proof of Proposition 47.12 holds as written, for the module and for its quotients by submodules of elements of value zero, the values factoring through them. When every active molecule has one mark, V_W is a point, the letters are monomials, the module is spanned by [1] (Theorem 48.3(iii)), and its one element [1] has the value $P_W \neq 0$. □

Theorem 48.24 (Several active molecules through their molecule families). *As stated.*

Proof. (i) With $\mathbf{J}^2 = b\mathbf{J}$ for the matrix of ones of size b, $(\mathbf{I}+\delta\mathbf{J})^{-1} = \mathbf{I} - \frac{\delta}{1+\delta b}\mathbf{J}$, and $\mathbf{e}_{T_i} + \delta\mathbf{1} = (\mathbf{I}+\delta\mathbf{J})\mathbf{e}_{T_i}$. So $\theta_j = \bigotimes_i(\mathbf{I}+\delta\mathbf{J}_{j,i})\, c_j^{(\delta)} = \sum_{T'} c_{j,T'}^{(\delta)} \bigotimes_i(\mathbf{e}_{T_i'} + \delta\mathbf{1})$, the vectors on the bases of table j being the tensors of vectors on the bases of its restrictions (7.9). The entries of $c_j^{(\delta)}$ are those of θ_j plus $O(\delta)$, and $\theta_j > 0$, so they are positive for small δ; then every $\theta_{j,T'}^{(i)}$ is positive, its entries being δ or $1+\delta$ times a positive number, and $\theta_{j,T} = \sum_{T'} \prod_i \theta_{j,T'}^{(i)}(T_i)$.

(ii) For a letter K_j with $|R_j| \geq 2$ and a point of the orthant, Corollary 4.4 with $X_r = \prod_i K_{j,r}^{(i)}(\alpha) > 0$ gives

$$K_j^{-s_j} = \int_{\sum_r z_{j,r}=s_j} \Gamma_{|R_j|}\begin{bmatrix}\mathbf{z}_j\\ s_j\end{bmatrix} \prod_{r\in R_j}\prod_i K_{j,r}^{(i)}(\alpha)^{-z_{j,r}}$$

through $\mathbf{c}_j$, converging absolutely, and likewise for Ψ_j; with $|R_j| = 1$, $K_j^{-s_j} = \prod_i K_{j,r}^{(i)}(\alpha)^{-s_j}$. Multiplying, the master form of W is the fibre integral of the kernel times

$$\prod_{i=1}^{q}\Big(\alpha_{M_i}^{\mathbf{m}_{M_i}} \prod_{j,r} K_{j,r}^{(i)}(\alpha_{M_i})^{-z_{j,r}}\Psi_{j,r}^{(i)}(\alpha_{M_i})^{-z_{j,r}^*}\Big)\,dy,$$

the factor i depending only on the marks of M_i. On the pins its degree in those marks is $m_{M_i} - \sum_{j,r}\big(z_{j,r}r_j(M_i) + z_{j,r}^*(|M_i| - r_j(M_i))\big) = \kappa_{M_i} = 0$ on $\mathbb{D}_W$: the data of $F^{(i)}$ lie on its balance wall. Its wall at $U \subseteq M_i$, nonempty and proper, is $m_U - \sum_{j,r}\big(z_{j,r}d_j(U) + z_{j,r}^* d_j^*(U)\big)$, the least numbers of marks of U in a basis of $\mathcal{B}_j|M_i$ and in its complement in M_i being those in a basis of $\mathcal{B}_j$ and in its complement, every basis being a union; on the pins it is κ_U. V_W is the product of the spaces $\mathbb{R}^{M_i}/\mathbb{R}\mathbf{1}$, its measure that of the charts $y_{e_i} = 0$, and the integral of factor i over its space is $P_{F^{(i)}}(\mathbf{m}_{M_i};\mathbf{z},\mathbf{z}^*)$ (Definition 48.1(v)). On the orthant $|X_r^{-z_r}| = X_r^{-c_r}$ and $|\alpha^{\mathbf{m}}| = \alpha^{\operatorname{Re}\mathbf{m}}$, so by Tonelli the double integral of the modulus, over V_W and the fibre, is the product of the integrals over the fibre of the moduli of the stacked Gammas, finite by the decay of the Gamma function along vertical lines (Corollary 4.4), and of the periods $P_{F^{(i)}}(\operatorname{Re}\mathbf{m}_{M_i};\mathbf{c},\mathbf{c}^*)$, finite since their walls are the positive $\kappa_U(\operatorname{Re}\mathbf{d})$. So Fubini gives the identity at every such data.

The pins $\sum_r z_{j,r} = s_j$, $\sum_r z_{j,r}^* = t_j$ have independent rows and rational coefficients; the kernel is a quotient of Gamma functions of linear forms with integral values on the lattice; the maps $\iota_i(\mathbf{d},\mathbf{z}) = (\mathbf{m}_{M_i};\mathbf{z},\mathbf{z}^*)$ are linear, integral on the lattice, and onto the balance wall of $F^{(i)}$, a point of which is reached with the exponents of F the sums of its exponents over r and the masses of the other molecules balanced. A point admissible at $\mathbf{d}$ has every node in its tube, so every $\kappa_U(\operatorname{Re}\mathbf{d}) > 0$ and $\mathbf{d}$ is in the tube of W; a positive direction of W (Theorem 48.3(i)), with the exponent of every letter split equally over R_j, is admissible, its walls κ_U being positive whatever the shares. So this is a positive share reading (Definition 48.4). An integral point of $\mathbb{D}_W$ is the

image of the integral shares that put the whole exponent of each letter on one element of R_j; so the lattice maps onto $\mathbb{D}_W(\mathbb{Z})$, and Theorem 48.5 holds for the reading, its nodes the molecule families, isomorphic ones having one module (48.5(v)). With one element in every R_j the pins fix the shares, the fibre is a point, the stacked Gammas are 1, and $P_{V_F} = \prod_i P_{F^{(i)}}$. The letters $|\alpha_{M_i}|$ of W^+ are letters of tables whose bases lie in M_i, which factor with one term, so they go unchanged to the molecule family of M_i, and the same proof holds for P_{W^+}. □

Definition 48.25 (The procedure in all the data). As stated.

Proof. Every step is a definition or a theorem cited in it, applied to data that its hypotheses allow. The letters, the active tables and the active molecules are read off the tables and the names of the exponents fixed at 0, and W and W^+ are not empty, some exponent not being fixed at 0. The target, the Gamma factors and the certificates are those of Proposition 48.21; a factorization exists (Theorem 48.24(i)), and a molecule family is a family of letters of tables on one molecule, so the steps for one active molecule apply to it. The tree, the seam letters, the transfer tensors, the node words and the full nodes are those of Definitions 16.14, 29.9 and 48.11 for one molecule, and the blocks those of Definition 48.13. The sets Σ with their partitions are finitely many, the root being full, and the work of each is known once the dimensions of (9) are. □

Theorem 48.26 (The procedure in all the data reads every family). *As stated.*

Proof. (i) The question is finite: the balance is one linear form, the target and the walls κ_{M_i} are rational functions of the data (Proposition 48.21), the active molecules are the classes of the linking in the active tables, and the factorization of (5) is found at the first k at which the coordinates of Theorem 48.24(i) are positive, which comes. The classification is finite: steps (1)–(5) of Definition 16.14 are, the seam letters and the transfer tensors are polynomials read off the tables (Definition 48.11), the absent stations, the absent exponents and the finest separated partitions are read off the seam letters (Definition 48.13), and the classes are found by finitely many bijections. The searches stop:

- for masters from a box, Proposition 47.13(iii), with Theorem 48.3(iv) for families of positive letters;
- for an accepted set on the shares, Theorem 48.18(iv), its certificates being identities on products of masters, which (9) gives with their shift matrices at the generators and their negatives;
- for an accepted set of shifts of a block, Theorem 48.20(iii), (iv);
- for the law of an element along a native direction of a subspace of the data, in the module on that subspace, Proposition 47.14(iv).

The work of every Σ is a number once the dimensions of the kept classes are known (Theorem 48.15(iii)). Value zero takes finitely many closings, each the constant term of a Laurent polynomial, computed through the tree by finite sums (Theorem 48.18(v), Proposition 47.12, Theorem 48.23), along a direction found by finitely many evaluations of polynomials (Proposition 47.12(ii)); on the hyperplane $\mathbb{E}_S^\sharp$ of a root seen by its scales with children it takes finitely many coefficients of the expansion at the native gauge of a native direction (proof of Theorem 48.20(vii), *The hyperplane*), its coordinates algebraic over $\Bbbk$ and rational when the weights are rational, each a rational function formed from finitely many Taylor coefficients and Gaussian moments, up to the bound read off the law (Proposition 47.14(ii), (iv)). The word is assembled from these

(Theorem 48.15). Every operation is over $\Bbbk$ or over a field of rational functions over $\Bbbk$ (Theorems 47.4(iv) and 48.3(iii)), but for the expansions, which are over the finite extension $\Bbbk(\alpha^\star)$ of $\Bbbk$ generated by the native gauge, $\Bbbk$ itself when the weights are rational and the gauge is taken rational (Proposition 47.14(ii)).

(ii) Proposition 48.21.

(iii) For one active molecule, Theorem 48.18(iii), (iv), V being the family W_F of the letters of its tables, with Σ the full nodes and the node modules of (9): the module presented at the root by an accepted set is the quotient of the module of V by a submodule of elements of value zero, the module itself (Proposition 47.15), with masters among the ε_λ and their shift matrices at the generators and their negatives. For several active molecules, Proposition 47.13: masters of the module itself. In both cases the values are well defined on the module presented and are carried by its matrices (Theorem 47.4(i), (v), with Theorem 48.3(iii)), and every insertion f_λ is reduced by a path in the generators and their negatives. The certificates are those of Theorem 47.8(ii), of Proposition 47.13(ii) and of Theorem 48.18(iv).

(iv) Proposition 47.15: the module presented is the module of V, in which an element of value zero is 0, so its reduction on the masters decides; and Proposition 47.12 for it, with its closings computed through the tree (Theorem 48.18(v)) or as those of V (Theorem 48.23(ii)); Theorem 48.20(vii), with Propositions 47.13 and 47.15 and Theorem 48.23, for the inputs over their data, and with Proposition 47.14 on the hyperplane $\mathbb{E}_S^\sharp$ for the input of a root seen by its scales with children over the data of F; the coefficients of the expansion are rational functions over the field generated by the weights, the coefficients of the element and the native gauge, over $\mathbb{Q}$ when the weights and the element are rational and the native gauge is the rational one of Proposition 47.14(i) (Proposition 47.14(ii)).

(v) Theorem 48.15 at such data, at complex data by (v) there, the modules N_r presented from the modules of the transforms of the blocks (Theorem 48.20(vi), the children of the blocks of Σ being full); Theorem 47.4(v), with Theorem 48.3(iii), carries the values of the masters to the lattice translates, and Theorems 47.2(ii) and 48.3(ii) give the continuation. For several active molecules, Theorem 48.24(ii), each molecule family read by (iii) and (iv) in all its data. Along the contour of the shares the shares have the positive real parts $c_{j,r}$, $c^*_{j,r}$, the data of a molecule family lie on its balance wall, and its walls are walls of F, positive at the real parts of the data of F (Theorem 48.24(ii)); so the real parts of its data are real data on its balance wall with its exponents and its proper walls positive, at which it has a native gauge (the argument of Proposition 47.14(i)), and Theorem 48.15(v) reads it in words at the complex data of the contour.

(vi) Theorems 48.5(v), 48.18(iii) and 48.20(vi). □

50.48 Chapter 49: the family as inference

50.48.1 Samples of bases

Every statement of this section rests on one factorization: the chance of a sample of a family is the product over its draws of the chances of single bases, each of which factors over the patterns of a bunch, and the product over all the draws is $\theta_{\text{draws}}\alpha^{\mathbf{m}}/\prod_j K_j(\alpha)^{s_j}\Psi_j(\alpha)^{t_j}$.

Proposition 49.3 (What the data see of the bases). *As stated.*

Proof. (i) is a property of one table. For $e \in C$, $C \setminus e$ is independent by the minimality of C and lies in a basis T, which does not contain C; so $T \cap C = C \setminus e$. Hence $r(C) = k - 1$, every $C \setminus e$ is

a pattern of C, and C, not independent, is not. For $k \geq 3$ two marks e, f of C lie in $C \setminus g$ for a third $g \in C$, hence in a common basis.

(ii) The level of a basis draw of table j lies in the window $[d_j(S), r_j(S)]$ of S (Theorem 7.13), and the colevel of a cobasis draw is $|S| - |T' \cap S| \in [|S| - r_j(S), |S| - d_j(S)] = [d_j^*(S), |S| - d_j(S)]$. Some basis reaches $r_j(S)$ and every basis has positive chance, so $p_j > 0$; the s_j basis draws of table j are independent, and none reaches $r_j(S)$ with the chance $(1 - p_j)^{s_j}$. The same holds at $d_j(S)$, and for the cobasis draws with $\mathbb{P}^*_{j,\alpha}$ and t_j. □

Proposition 49.4 (The exact laws of a sample of bases). *As stated.*

Proof. (i) With $p = T \cap B$ and the weights $\theta_{j,(p),T\setminus p} = \theta_{j,T}$ of the child (Definition 12.1),

$$\mathbb{P}_{j,\alpha}(T) = \frac{\theta_{j,T}\alpha^T}{K_j(\alpha)} = \frac{\alpha_B^p K_{j,(p)}(\alpha_R)}{K_j(\alpha)} \cdot \frac{\theta_{j,(p),T\setminus p}\, \alpha_R^{T\setminus p}}{K_{j,(p)}(\alpha_R)},$$

and, since $\alpha^{\mathcal{E}\setminus T} = \alpha_B^{B\setminus p}\alpha_R^{R\setminus(T\setminus p)}$,

$$\mathbb{P}^*_{j,\alpha}(T) = \frac{\alpha_B^{B\setminus p}\Psi_{j,(p)}(\alpha_R)}{\Psi_j(\alpha)} \cdot \frac{\theta_{j,(p),T\setminus p}\, \alpha_R^{R\setminus(T\setminus p)}}{\Psi_{j,(p)}(\alpha_R)},$$

the first factors the pattern probabilities (Theorem 12.8) and the second the basis and cobasis laws of the child at α_R. The draws are independent, so the patterns of the basis draws of table j are independent with the chances $\pi_{j,p}(\alpha)$ and their numbers $a_{j,p}$ form a multinomial vector of size s_j, likewise the $b_{j,p}$ of size t_j; and given all the patterns the room parts are independent with the laws of the children. A basis draw with pattern p uses $e \in B$ exactly when $e \in p$, and a cobasis draw with pattern p uses e, by missing it, exactly when $e \notin p$; so $m_e = \sum_j \left(\sum_{p \ni e} a_{j,p} + \sum_{p \not\ni e} b_{j,p} \right) = \mathrm{load}_e$ (Definition 12.24). In the room a basis draw uses the marks of $T \setminus p$, and a cobasis draw the marks of $R \setminus (T' \setminus p)$, which it misses: what the draws of the children use. The mean of a multinomial vector is its size times its chances, which at a native gauge is the native split of Definition 12.25.

(ii) The chance of a sample is

$$\prod_{j,i} \frac{\theta_{j,T_{j,i}}\alpha^{T_{j,i}}}{K_j(\alpha)} \prod_{j,i} \frac{\theta_{j,T'_{j,i}}\alpha^{\mathcal{E}\setminus T'_{j,i}}}{\Psi_j(\alpha)} = \frac{\theta_{\mathrm{draws}}\, \alpha^{\mathbf{m}}}{\prod_j K_j(\alpha)^{s_j}\Psi_j(\alpha)^{t_j}}.$$

Expanding $\prod_j K_j^{s_j}\Psi_j^{t_j}$ draw by draw, every sample contributes the monomial $\theta_{\mathrm{draws}}\alpha^{\mathbf{m}}$ of its counts, so the samples with the counts $\mathbf{m}$ have the total chance $\Theta_F(\mathbf{m})\alpha^{\mathbf{m}}/\prod_j K_j^{s_j}\Psi_j^{t_j}$, $\Theta_F(\mathbf{m})$ the coefficient of $\alpha^{\mathbf{m}}$; the ratio is $\theta_{\mathrm{draws}}/\Theta_F(\mathbf{m})$.

(iii) κ_S is the sum over the draws of $|T_{j,i} \cap S| - d_j(S)$ and $|S \setminus T'_{j,i}| - d_j^*(S)$ (Proposition 49.1(iii)), independent, with the generating functions $\mathsf{Q}^K_{j,S}(x;\alpha) = \mathbb{E}_{T\sim\mathbb{P}_{j,\alpha}}[x^{N_S - d_j(S)}]$ and $\mathsf{Q}^\Psi_{j,S}(x;\alpha)$ (Definition 12.10); so the generating function of κ_S is the product. Each factor has degree $c_j(S)$ and every coefficient from degree 0 to $c_j(S)$ positive, every level of the window being reached by some basis (Theorem 7.13); so the values of κ_S fill the stated range and the product at $x = 0$ is positive. The mean of a level excess is $\sum_{e\in S} R_{j,e}(\alpha) - d_j(S)$ and that of a colevel excess $\sum_{e\in S} \mathbb{P}^*_{j,\alpha}(e \notin T) - d_j^*(S) = \sum_{e\in S} R^*_{j,e}(\alpha) - d_j^*(S)$; the cumulants of order $k \geq 2$ of an excess are those of its level, $\sum_i \varkappa_k$ of the coins (Proposition 12.11(iv)), and summed with the sizes they are $\partial_S^k \Phi(\log \alpha)$ (Proposition 12.12). With a positive spectrum each excess is a sum of independent coins (Proposition 12.11(iv)), and κ_S is the sum of all of them. □

Proposition 49.5 (Tests that do not see the gauge). *As stated.*

Proof. (i) is Proposition 49.4(ii); for lists $\theta_{\text{draws}} = 1$. (ii) $\mathbb{P}(A) = \sum_{\mathbf{m}} \mathbb{P}(\mathbf{m})\, \mathbb{P}(A \mid \mathbf{m}) \le \sum_{\mathbf{m}} \mathbb{P}(\mathbf{m})\, \varepsilon = \varepsilon$, the conditional chances being free of the gauge by (i). (iii) The samples of F' with the counts $\mathbf{m}$ are those of F whose every draw is a basis of its table in F', with the same θ_{draws}; by (i) their conditional chance under F is $\Theta_{F'}(\mathbf{m})/\Theta_F(\mathbf{m})$. The rejection region, the union over the $\mathbf{m}$ with $p_{F'|F}(\mathbf{m}) \le \varepsilon$ of these samples, carries at most $\varepsilon \Theta_F(\mathbf{m})$ of the weight at every $\mathbf{m}$, and (ii) applies. A draw that is not a basis of its table in F' has chance zero under F' at every gauge. (iv) The true family is rejected with chance at most ε. □

Corollary 49.6 (The evidence of a family). *As stated.*

Proof. The centre of strengths $\boldsymbol{\sigma}_0$ is a question with every proper wall positive on a connected family. If every draw is a basis of its table of F, Proposition 49.2(ii) with the prior question $(\sigma_0 \mathbf{1}; \boldsymbol{\sigma}_0, \boldsymbol{\sigma}_0)$ gives the chance of the sample with the tilt integrated out, which on the balance wall is the gauge integrated out up to its scale, on which the chance of the sample does not depend (Proposition 49.1(i)). Otherwise the sample has chance zero under F at every gauge. The posterior over the collection is the prior times this chance, normalized. □

Remark. At one table, (i) and (ii) of Proposition 49.4 are the reference's statement, with $s = q$ and $t = 0$, and Proposition 49.5 and Corollary 49.6 at one list are the reference's. Part (iii) of Proposition 49.4 is the family reading of Proposition 49.3(ii): the floors of the windows of every table are seen together through the one wall κ_S of the sample, whose chance of vanishing is $\prod_j \mathsf{Q}^K_{j,S}(0;\alpha)^{s_j} \mathsf{Q}^{\Psi}_{j,S}(0;\alpha)^{t_j}$.

50.48.2 Statistics from a centre

Proposition 49.16 (The even and odd statistics from a centre). *As stated.*

Proof. (i) The law of Z is that of the question $(0; \boldsymbol{\sigma}, \mathbf{0})$, whose exponent is $-\sum_j \sigma_j E_j$ (Definition 17.1). The centre is inside its walls, so the family is connected, and by Proposition 17.4(iii) $\sum_j \sigma_j E_j$ is strictly convex and even, least only at 0, with $\sum_j \sigma_j E_j(0) = 2 \sum_j \sigma_j \log K_j(\mathbf{1})$. Its Hessian at 0 is $\sum_j \sigma_j \cdot 2 \operatorname{Cov}_{\mathbb{P}_{j,\mathbf{1}}}(\chi_T) = 8 \sum_j \sigma_j \kappa_{j,\mathbf{1}}(X_e, X_f)$, which is rung two of the still of the realization $\big((\sigma_j, \sigma_j)_j; \mathbf{1}\big)$ by Proposition 9.7. For one table, E_j is convex and even with its least value $2 \log K_j(\mathbf{1})$ at 0. If v is constant on the molecules of table j, $\langle \chi_T, v \rangle = c$ for every basis (Proposition 7.9), so $\Lambda_j(z+v) = e^c \Lambda_j(z)$, $\Lambda_j(-z-v) = e^{-c} \Lambda_j(-z)$, and $E_j(z+v) = E_j(z)$; in particular $E_j(v) = E_j(0)$. Conversely if $E_j(z) = E_j(0)$, the convex function $t \mapsto E_j(tz)$ has its least value at $t = 0$ and at $t = 1$ and so is constant on $[0,1]$; its second derivative at 0, $2 \operatorname{Var}_{\mathbb{P}_{j,\mathbf{1}}} \langle \chi_T, z \rangle$, vanishes, and z is constant on the molecules of table j (Lemma 7.8). The Laplace transform is Proposition 17.7(i) at $c = 0$, $\mathbf{a} = \mathbf{k}$, $\mathbf{b} = 0$: the question $(0; \boldsymbol{\sigma} + \mathbf{k}, \mathbf{0})$ is the centre of strengths $\boldsymbol{\sigma} + \mathbf{k}$, with the data $\big((\sigma + |\mathbf{k}|)\mathbf{1}; \boldsymbol{\sigma} + \mathbf{k}, \boldsymbol{\sigma} + \mathbf{k}\big)$, and its walls are $\kappa^{\mathbf{E}}_S(\boldsymbol{\sigma} + \mathbf{k}) = \kappa^{\mathbf{E}}_S(\boldsymbol{\sigma}) + \kappa^{\mathbf{E}}_S(\mathbf{k})$. Along $\mathbf{k} = \lambda \boldsymbol{\sigma}$ they are $(1+\lambda)\kappa^{\mathbf{E}}_S(\boldsymbol{\sigma})$, all zero at $\lambda = -1$; along $\lambda \mathbf{k}$ the first to vanish is at the least ratio stated.

(ii) The density $e^{-\sum_j \sigma_j E_j(z)}$ is even, and $z \mapsto -z$ keeps every E_j and negates every O_j; so the two triples have one law, and a joint moment of odd total degree in Z and the $O_j(Z)$, finite as the density decays exponentially (Proposition 17.4) while the statistics grow linearly, equals its own negative. The Laplace transform and its domain are Proposition 17.7(i) at $\mathbf{a} = 0$. When $|b_j| \le \sigma_j$ and $\ell^*_{\boldsymbol{\sigma}}(c, \mathbf{b}) > 1$, the question $(c; \boldsymbol{\sigma}, \mathbf{b})$ has nonnegative exponents and every proper wall positive, so it has a native gauge (Theorem 8.19(iii)), its target is its masses, and its period over

P_{c} is its pseudoexpectation (Definition 16.10(iii)). The tails are Proposition 17.8 at the centre; when $\ell^*_{\boldsymbol{\sigma}}(c,\mathbf{b})=\infty$ both Y and $-Y$ are bounded above, and Y is bounded.

(iii) By Theorem 7.15(i), $K_j(\alpha)=e^{\langle\mathbf{1},z\rangle}\Lambda_j(z)$ and $\Psi_j(\alpha)=e^{\langle\mathbf{1},z\rangle}\Lambda_j(-z)$, and $\log\Lambda_j(\pm z)=\frac12\big(E_j(z)\pm O_j(z)\big)$. So $K_j^{-s_j}=e^{-s_j\langle\mathbf{1},z\rangle}e^{-\frac{s_j}{2}(E_j+O_j)}$ is the factor of table j at $(\sigma_j,\delta_j)=(\frac{s_j}{2},\frac{s_j}{2})$, its factor $e^{-s_j\langle\mathbf{1},z\rangle}=\alpha^{-\frac{s_j}{2}\mathbf{1}}$ the shift of the masses, and likewise $\Psi_j^{-t_j}$. Splitting each table into its two letters, at $(s_j,0)$ and $(0,t_j)$, keeps the family word, and the pair coordinates add: $(\frac{s_j}{2}+\frac{t_j}{2},\frac{s_j}{2}-\frac{t_j}{2})=(\sigma_j,\delta_j)$. □

Proposition 49.17 (What the two statistics are). *As stated.*

Proof. For scores a_T with weights $\theta_T>0$, $\max_T(a_T+\log\theta_T)\le\log\sum_T\theta_Te^{a_T}\le\max_T a_T+\log\sum_T\theta_T$: a soft maximum; and $-\log\sum_T\theta_Te^{-a_T}$ is a soft minimum. (i) $E_j=\log\Lambda_j(z)+\log\Lambda_j(-z)$ and $O_j=\log\Lambda_j(z)-\log\Lambda_j(-z)$ are the soft maximum less, and plus, the soft minimum, and $\Phi^\circ=\sum_j\big(s_j\log\Lambda_j(z)+t_j\log\Lambda_j(-z)\big)$ (Theorem 8.19). (ii) By Theorem 7.16 at $\alpha=\mathbf{1}$, $\Lambda_j(z)/\Lambda_j(0)=\mathbb{E}_{T\sim\mathbb{P}_{j,\mathbf{1}}}[e^{Y_j}]$, so near 0, $\log\Lambda_j(z)=\log K_j(\mathbf{1})+\sum_{k\ge1}\frac{1}{k!}\kappa_{j,\mathbf{1}}(Y_j^{\times k})$ and $\log\Lambda_j(-z)$ is the same with $(-1)^k$; their sum and difference are the two expansions. $\kappa_{j,\mathbf{1}}(Y_j)=\sum_e z_e\mathbb{E}[\chi_{T,e}]=\sum_e(2R_{j,e}(\mathbf{1})-1)z_e$, and for $k\ge2$ multilinearity and $\chi_T=2X-\mathbf{1}$ give $\kappa_{j,\mathbf{1}}(Y_j^{\times k})=\sum_w z^w\kappa_{j,\mathbf{1}}(\chi_{T,w_1},\dots,\chi_{T,w_k})=2^k\sum_w z^w\kappa_{j,\mathbf{1}}(w)$, a constant shift not entering a cumulant of order $k\ge2$. The terms of order $k\ge2$ of Φ° are then $\frac{1}{k!}\sum_w 2^k\sum_j\big(s_j+(-1)^kt_j\big)\kappa_{j,\mathbf{1}}(w)z^w$, which at the exponents of a realization is $\frac{1}{k!}\sum_w\kappa_\Upsilon(w)z^w$ (Proposition 9.7). (iii) $|\log\Lambda_j(z)-h_j(z)|\le\max(|\log\theta_{j,\min}|,|\log K_j(\mathbf{1})|)$, so $E_j(\lambda z)-\lambda\,\mathrm{wd}_j(z)$ and $O_j(\lambda z)-\lambda(h_j(z)-h_j(-z))$ are bounded; divide by λ. On the sector of π the largest score is at $T^+_{j,\pi}$ and the least at $T^-_{j,\pi}$ (Lemma 8.3), and $\sum_j\big(s_jh_j(z)+t_jh_j(-z)\big)=\langle\sum_j(s_j\chi_{T^+_{j,\pi}}+t_j\chi_{\mathcal{E}\setminus T^-_{j,\pi}}),z\rangle=\langle2v_\pi-2\sigma\mathbf{1},z\rangle$; for $s_j,t_j\ge0$, in the interior of the sector $\mathbf{1}_{T^+_{j,\pi}}$ and $\mathbf{1}_{\mathcal{E}\setminus T^-_{j,\pi}}$ are the only points of P_j and P_j^* at which $\langle\cdot,z\rangle$ is largest, so v_π is the vertex of $\mathcal{N}_F$ at which it is largest. By Proposition 17.4(i), $|X+2\kappa|$ is bounded, so $X(\lambda z)/\lambda\to-2\kappa(z)$, and on $\mathbf{1}^\perp$, where $\langle\mathbf{1},z\rangle=0$ and $\langle\boldsymbol{\mu}_\perp,z\rangle=\langle\mathbf{m},z\rangle$, $2\kappa(z)=\langle2v_\pi-2\sigma\mathbf{1},z\rangle-2\langle\boldsymbol{\mu}_\perp,z\rangle=2\langle v_\pi-\mathbf{m},z\rangle$. At the tilt $-\mathbf{1}_{U_k}+\frac{|U_k|}{n}\mathbf{1}\in H_\pi\cap\mathbf{1}^\perp$ this reads $\kappa_{U_k}=m_{U_k}-(v_\pi)_{U_k}$, the term in $\mathbf{1}$ dropping because $(v_\pi)_\mathcal{E}=\sum_j(s_jr_j+t_jr_j^*)=m_\mathcal{E}$ on the balance wall. □

Remark. At one table and the centre of strength σ_0, Proposition 49.16 is the reference's, with $\ell^*_{\sigma_0}(0,b)=\sigma_0\,\ell^*_1(0,1)/|b|$; Proposition 49.17(i)–(ii) for one table is the reference's statement, and the family adds the still and, in (iii), the greedy vertex of the Newton sum, whose tail sums against the masses are the walls along the order: the reading of the walls of Theorem 8.19(iii) at the vertex that the order selects.

50.48.3 The Grey law, the dial and the sorted draw

Proposition 49.12(iii) (The tails of the Grey law). *As stated, for every real direction of the exponents.*

Proof. Let F_0 be the family of the list $\binom{\mathcal{E}}{1}$, whose bases are the singletons and whose letter is $K_0=|\alpha|$, and let F' be the family of the tables of F at the exponents $(0,0)$ and the list $\binom{\mathcal{E}}{1}$ at $(m_\mathcal{E},0)$. These data are on the balance wall of F', the list $\binom{\mathcal{E}}{1}$ having rank one; that table has least level 0 on every proper set, so the walls are $\kappa_S=m_S>0$; and the law of the question is $\mathrm{Dir}_{\mathbf{m}}$ (Proposition 16.3). Let v be the balanced direction of the data that keeps the masses, moves the exponents of table j of F by (a_j,b_j) and those of the list $\binom{\mathcal{E}}{1}$ by $(-d,0)$, $d=\sum_j(a_jr_j+b_jr_j^*)$.

Along $q+\lambda v$ the walls are $m_S-\lambda g(S)$, so the λ^* of Proposition 17.8 is k^*. The statistic Y of that proposition is $X_v(Z)$, the logarithm of the ratio of the integrands of the periods at $q+v$ and at q (Definition 17.1, and the proof of Proposition 17.4(i)), which at the tilt Z of U is $\log\big(\prod_j K_j(U)^{-a_j}\Psi_j(U)^{-b_j}K_0(U)^d\big)=\sum_j(a_jG_j+b_jG_j^*)$, as $K_0(U)=|U|=1$ on the simplex. Proposition 17.8 gives the tail when $k^*<\infty$, and the bound above when $k^*=\infty$. □

Remark. The reference reads (iii), for $a_j,b_j\ge 0$, off the abscissa of convergence of the Laplace transform of (i), which gives the limit superior; the argument above gives the limit, at every real direction. In the direction $(\mathbf{s},\mathbf{t})$ of a word it is the tail of Proposition 49.15(iv), which the reference proves from the collapse of a set attaining k^*.

Proposition 49.15 (The exponent is a dial between the mean and the maximum). *As stated, for real exponents of any signs, not all zero.*

Proof. (i) is a property of power means and does not involve the exponents. (ii) By Proposition 49.10(ii), $\mathbb{E}[e^{kA_k}]=\frac{1}{q}\sum_i\mathbb{E}[W(U_i)^k]=P_F(\mathbf{m};k\mathbf{s},k\mathbf{t})/\Gamma^n_1\begin{bmatrix}\mathbf{m}\\ m_{\mathcal{E}}\end{bmatrix}$ wherever every proper wall at $(\mathbf{m};k\mathbf{s},k\mathbf{t})$, which is $m_S-kg(S)$, is positive, that is for $0<k<k^*$; and $e^{kA_k}=\frac{1}{q}\sum_i W(U_i)^k$ has a finite variance exactly when $\mathbb{E}[W(U)^{2k}]<\infty$, that is $2k<k^*$ (Proposition 49.10(i) at the exponents $(2k\mathbf{s},2k\mathbf{t})$). (iii) For $k\ge k^*$ some proper wall at $(\mathbf{m};k\mathbf{s},k\mathbf{t})$ is not positive, and $\mathbb{E}[W(U)^k]=\infty$ by Proposition 49.10(i); the law of the maximum of independent draws is the power of the law of one. (iv) $Y=\sum_j(s_jG_j+t_jG_j^*)$ with $(G_j,G_j^*)_j\sim\mathrm{Grey}(F;\mathbf{m})$, and Proposition 49.12(iii) in the direction $(\mathbf{s},\mathbf{t})$ gives the tail and the bound. For $s_j,t_j\ge 0$: $(|U_S|,|U_{\mathcal{E}\setminus S}|)\sim\mathrm{Dir}_{(m_S,m_{\mathcal{E}\setminus S})}$ by the aggregation of the coordinates of a Dirichlet draw; on the simplex every coordinate in S is at most ρ and every coordinate at most 1, so $K_j(U)\le K_j(\mathbf{1})\rho^{d_j(S)}$ and $\Psi_j(U)\le\Psi_j(\mathbf{1})\rho^{d_j^*(S)}=K_j(\mathbf{1})\rho^{d_j^*(S)}$, and raising these to the powers $-s_j\le 0$, $-t_j\le 0$ gives the bound on $W(U)$. □

Proposition 49.19 (A sorted draw lives on the sector of its order). *As stated, for real exponents of any signs.*

Proof. The family is connected: on the balance wall $\kappa_S+\kappa_{\mathcal{E}\setminus S}=2\sum_j\sigma_jc_j(S)$ (Lemma S5), so positive walls put on every nonempty proper S a table with $\sigma_j>0$, hence active, and $c_j(S)>0$. The tilt Z of U has the density $2^{n-1}e^{X(z)}/P_F(\mathbf{m};\mathbf{s},\mathbf{t})$ with respect to dz (Definition 17.1), and on the sector H_π, where dz is the Lebesgue measure in the differences v_k, Proposition 17.4(i) gives $e^{X(z)}=e^{-2\sum_k\kappa_kv_k}\prod_j k_{j,\pi}(q)^{-s_j}\psi_{j,\pi}(q)^{-t_j}$ with $q_k=e^{-2v_k}$, at any signs of the exponents. In the gaps $u_k=2v_k=\log(U_{\pi(k-1)}/U_{\pi(k)})$, $du=2^{n-1}dv$, so on H_π the gaps have the density $P_F(\mathbf{m};\mathbf{s},\mathbf{t})^{-1}e^{-\sum_k\kappa_ku_k}\prod_j k_{j,\pi}(e^{-u})^{-s_j}\psi_{j,\pi}(e^{-u})^{-t_j}$ on $[0,\infty)^{n-1}$, whose total is $I_\pi/P_F(\mathbf{m};\mathbf{s},\mathbf{t})$ (Corollary 8.6); the boundaries of the sectors are null, and summing over π gives $P_F(\mathbf{m};\mathbf{s},\mathbf{t})=\sum_\pi I_\pi$. This is (i) and (ii). (iii) The bounds on the sector letters are those of Proposition 17.4(i); raised to the powers $-s_j$ and $-t_j$, of any signs, they bound $\prod_j k_{j,\pi}^{-s_j}\psi_{j,\pi}^{-t_j}$ on the cube between two positive constants, and for $s_j,t_j\ge 0$ between $\prod_j K_j(\mathbf{1})^{-s_j-t_j}$ and $\prod_j\theta_{j,T^+_{j,\pi}}^{-s_j}\theta_{j,T^-_{j,\pi}}^{-t_j}$; and $\int_{[0,\infty)^{n-1}}e^{-\sum_k\kappa_ku_k}du=\prod_k\kappa_k^{-1}$. (iv) is Lemma 8.3, which does not involve the exponents. □

Remark. Proposition 49.14 is the ratio of two limits of Theorem 17.5(i): by Proposition 49.10(i), $\mathbb{E}_{V\sim\mathrm{Dir}_{\lambda\boldsymbol{\tau}}}\big[\prod_j K_j(V)^{-\lambda s_j}\Psi_j(V)^{-\lambda t_j}\big]=P_F(\lambda\boldsymbol{\tau};\lambda\mathbf{s},\lambda\mathbf{t})/\Gamma^n_1\begin{bmatrix}\lambda\boldsymbol{\tau}\\ \lambda\tau_{\mathcal{E}}\end{bmatrix}$, the numerator is the period of λ times the question of data $(\boldsymbol{\tau};\mathbf{s},\mathbf{t})$, with the walls $\tau_S-g(S)$, and the denominator is the period of the list $\binom{\mathcal{E}}{1}$ at a full basis lean at the masses $\lambda\boldsymbol{\tau}$, with the walls $\lambda\tau_S$ (Proposition 16.3); multiplied by λ^{n-1} they tend to $\sum_\pi\prod_k(\tau_{U_k}-g(U_k))^{-1}$ and $\sum_\pi\prod_k\tau_{U_k}^{-1}$.

50.48.4 The interaction of a bunch

The one-table proofs integrate the joint cumulant of the indicators of a bunch, one logarithm of a Taylor cube; a family integrates a sum of such logarithms with its exponents, one for each letter, so one lemma on one logarithm serves both.

Lemma S31 (An alternating sum over the subsets of a bunch)**.** *Let B be a finite set with $k = |B| \geq 2$, let $(c_p)_{p\subseteq B}$ be positive, and $f(y) = \log \sum_{p\subseteq B} c_p\, e^{\langle \mathbf{1}_p, y\rangle}$ on $\mathbb{R}^B$, and write $\partial^B = \prod_{e\in B} \partial_{y_e}$. Then $|\partial^B f(y)| \leq C\, e^{-\max_{e\in B}|y_e|}$, so $\partial^B f$ is integrable on $\mathbb{R}^B$, and*

$$\int_{\mathbb{R}^B} \partial^B f(y)\, dy = \sum_{p\subseteq B} (-1)^{|B\setminus p|} \log c_p.$$

Proof. The bound. $f(y+w) - f(y)$ is the logarithm of the moment generating function at w of the indicators $(X_e)_{e\in B}$ of a random set $P \subseteq B$ with the law $\pi_y(p) \propto c_p e^{\langle \mathbf{1}_p, y\rangle}$, so $\partial^B f(y)$ is their joint cumulant. Fix $e \in B$. A joint cumulant of $k \geq 2$ variables does not change when one of them is shifted by a constant, and it is a sum, with coefficients depending on k alone, of products of joint moments, one for each block of a partition of the k places, exactly one block holding the place of e. With $X_e - \mathbb{E}X_e$ in that place and $|X_f| \leq 1$, $|\partial^B f(y)| \leq C_k\, \mathbb{E}|X_e - \mathbb{E}X_e| = 2C_k p_e(1-p_e)$, $p_e = \pi_y(e \in P)$. Pairing each $p \not\ni e$ with $p+e$, the odds $p_e/(1-p_e) = \sum_{p\not\ni e} c_{p+e} e^{y_e} w_p \big/ \sum_{p\not\ni e} c_p w_p$, $w_p = e^{\langle \mathbf{1}_p, y\rangle} > 0$, lie between $\rho_- e^{y_e}$ and $\rho_+ e^{y_e}$, $\rho_\pm$ the largest and the least of the ratios c_{p+e}/c_p; so $p_e(1-p_e) \leq \min(\text{odds}, \text{odds}^{-1}) \leq \max(\rho_+, \rho_-^{-1})\, e^{-|y_e|}$. The best e gives the bound.

The value, by induction on k. Fix $e \in B$, put $B' = B - e$, $y' = y_{B'}$, and let $f^{/e}$ and $f^{\setminus e}$ be the functions of the same form on B' with the coefficients c_{p+e} and c_p, $p \subseteq B'$: the contraction and the deletion of e in the cube. With $\ell(x) = \log(1 + e^x)$,

$$f(y) = f^{/e}(y') + y_e + \ell\big(f^{\setminus e}(y') - f^{/e}(y') - y_e\big) = f^{\setminus e}(y') + \ell\big(y_e + f^{/e}(y') - f^{\setminus e}(y')\big).$$

Every derivative of ℓ is $O(e^x)$ as $x \to -\infty$, and every derivative of order at least one of $f^{/e}$ and $f^{\setminus e}$ is bounded; since $B' \neq \varnothing$, $\partial^{B'} y_e = 0$, so $\partial^{B'} f(y) \to \partial^{B'} f^{/e}(y')$ as $y_e \to +\infty$ and $\partial^{B'} f(y) \to \partial^{B'} f^{\setminus e}(y')$ as $y_e \to -\infty$. Hence $\int_{\mathbb{R}} \partial^B f\, dy_e = \partial^{B'} f^{/e}(y') - \partial^{B'} f^{\setminus e}(y')$ for every y', and by the bound and Fubini

$$\int_{\mathbb{R}^B} \partial^B f\, dy = \int_{\mathbb{R}^{B'}} \big(\partial^{B'} f^{/e} - \partial^{B'} f^{\setminus e}\big)\, dy'.$$

If $k \geq 3$, each term is integrable by the bound, and the induction gives $\sum_{p\subseteq B'} (-1)^{|B'\setminus p|} (\log c_{p+e} - \log c_p) = \sum_{p\subseteq B} (-1)^{|B\setminus p|} \log c_p$. If $k = 2$, $B' = \{e'\}$, the integrand is the derivative of $f^{/e} - f^{\setminus e} = \log\big((c_e + c_{ee'} e^{y'})/(c_\varnothing + c_{e'} e^{y'})\big)$, whose limits at $\pm\infty$ are $\log(c_{ee'}/c_{e'})$ and $\log(c_e/c_\varnothing)$; their difference is the alternating sum. □

Theorem 49.25 (The interaction totals the still over the bunch's scales). *As stated.*

Proof. Fix α_R. By the Taylor cube (Theorem 12.7)

$$\log K_j(e^{y_B}, \alpha_R) = \log \sum_{p\subseteq B} K_{j,(p)}(\alpha_R)\, e^{\langle \mathbf{1}_p, y_B\rangle},$$

with every $K_{j,(p)}(\alpha_R) > 0$ as $\mathrm{pat}_j(B) = 2^B$; Lemma S31 gives $\int \partial^B \log K_j\, dy_B = \iota_{j,B}(\alpha_R)$, absolutely. Likewise $\log \Psi_j(e^{y_B}, \alpha_R) = \log \sum_{P\subseteq B} \Psi_{j,(B\setminus P)}(\alpha_R)\, e^{\langle \mathbf{1}_P, y_B\rangle}$, and the lemma gives

$\sum_P (-1)^{|B\setminus P|}\log\Psi_{j,(B\setminus P)} = \sum_p (-1)^{|p|}\log\Psi_{j,(p)} = \iota^*_{j,B}(\alpha_R)$. The parts of the potential are these logarithms with the coefficients $\sigma_j(1,1)$ and $\delta_j(1,-1)$, and a table with both exponents zero does not enter; integrating term by term gives $\iota^{\mathbf{E}}_B$ and $\iota^{\mathbf{O}}_B$. At a realization $\kappa_\Upsilon(e_1,\dots,e_k) = 2^k\partial_{y_{e_1}}\cdots\partial_{y_{e_k}}\Phi$ (Definition 9.4), and Proposition 9.6 writes it through the cumulants at α and at α^{-1}. For one table at $(1,0)$, $\partial^B \log K(e^y) = \kappa_\alpha(e_1,\dots,e_k)$, the joint cumulant of the indicators under $\mathbb{P}_\alpha$ (Definition 7.17). □

Proposition 49.24 (The interaction belongs to the room). *As stated.*

Proof. (i) The child at p has rank $r_j - |p|$ on R (Lemma 12.2), so $K_{j,(p)}$ is homogeneous of degree $r_j - |p|$ and $\Psi_{j,(p)}$ of degree $|R| - r_j + |p|$. Under $\alpha_R \mapsto c\alpha_R$, $\iota_{j,B}$ moves by $\log c\sum_p (-1)^{|B\setminus p|}(r_j - |p|)$ and $\iota^*_{j,B}$ by $\log c\sum_p (-1)^{|p|}(|R| - r_j + |p|)$; both vanish, as $\sum_{p\subseteq B}(-1)^{|p|} = 0$ for $|B| \geq 1$ and $\sum_{p\subseteq B}(-1)^{|p|}|p| = 0$ for $|B| \geq 2$.

(ii) A basis draw of table j meets B in P with the chance $\pi_{j,P}(\alpha)$, and a cobasis draw misses exactly P on B when it meets B in $B\setminus P$, with the chance $\pi^*_{j,B\setminus P}(\alpha) = \alpha^P_B\Psi_{j,(B\setminus P)}(\alpha_R)/\Psi_j(\alpha)$ (Theorem 12.8); independence gives $w(P)$. So

$$\log w(P) = \sum_j (s_j + t_j)\langle y_B, \mathbf{1}_P\rangle + \sum_j \big(s_j \log K_{j,(P)}(\alpha_R) + t_j \log\Psi_{j,(B\setminus P)}(\alpha_R)\big) - \Phi(\log\alpha).$$

The coefficients of the expansion are $\lambda_A = \sum_{P\subseteq A}(-1)^{|A\setminus P|}\log w(P)$, and for $|A| \geq 2$ the terms constant in P and linear in $\mathbf{1}_P$ drop out:

$$\lambda_A = \sum_j \Big(s_j \sum_{P\subseteq A}(-1)^{|A\setminus P|}\log K_{j,(P)} + t_j \sum_{P\subseteq A}(-1)^{|A\setminus P|}\log\Psi_{j,(B\setminus P)}\Big),$$

free of α_B. At $A = B$ the second inner sum is $\iota^*_{j,B}$, and $\lambda_B = \iota^{\mathbf{E}}_B + \iota^{\mathbf{O}}_B$. For $A \subsetneq B$: the bases of table j that avoid $B\setminus A$ form its deletion of $B\setminus A$, a table as some basis avoids B, in which every subset of A is a pattern, with the children $K_{j,(P)}$, $P \subseteq A$; the bases that contain $B\setminus A$, less $B\setminus A$, form its contraction, a table as B is independent, in which every subset of A is a pattern and the pattern $P' \subseteq A$ has the child of the pattern $P'\cup(B\setminus A)$ of B. With $P' = A\setminus P$, $B\setminus P = P'\cup(B\setminus A)$, so the second inner sum is $\sum_{P'\subseteq A}(-1)^{|P'|}\log\Psi_{j,(P'\cup(B\setminus A))}$, the dual interaction of A in the contraction. The deletion is the restriction to $\mathcal{E}\setminus(B\setminus A)$, some basis avoiding $B\setminus A$, and these are the tables of the face of the wall at $B\setminus A$ on its room (Theorem 16.25), at the exponents $(s_j, 0)$ and $(0, t_j)$: every basis of the restriction and of the contraction comes from one basis of the table, whose weight it keeps, so the weights factor on the bottom levels as that theorem asks. So λ_A is $\iota^{\mathbf{E}}_A + \iota^{\mathbf{O}}_A$ computed in that face. At one table and $(1,0)$, $w(P) = \pi_P(\alpha)$. □

Proposition 49.26 (Both sides, and parity). *As stated.*

Proof. The child at p is a table on R, so $\Psi_{(p)}(\alpha_R) = \alpha^R_R K_{(p)}(\alpha_R^{-1})$ (Proposition 7.2); in z_R, $\log\Psi_{(p)} = 2\langle\mathbf{1}, z_R\rangle + \log K_{(p)}(e^{-2z_R})$, and as $\sum_p (-1)^{|p|} = 0$, $\iota^*_B(z_R) = \sum_p (-1)^{|p|}\log K_{(p)}(e^{-2z_R}) = (-1)^{|B|}\iota_B(-z_R)$. Substituting in Definition 12.18 gives $\iota^{\mathbf{E}}_B$ and $\iota^{\mathbf{O}}_B$; the parities in z_R and the values at $z_R = 0$ are read off. The total for $-\Phi$ is $-(\iota^{\mathbf{E}}_B + \iota^{\mathbf{O}}_B) = -\sum_j (s_j\iota_{j,B} + t_j\iota^*_{j,B})$. □

Remark. At one table and $(1,0)$ these are the reference's statements: the interaction, its homogeneity and log-linear reading, its total as the integral of the joint cumulant, and the reading of the dual table. In a family every subset of the bunch must be a pattern in every active table, and the family reads the alternating sum over the patterns of its whole potential: the term of the pattern P is the family of the children $K_{j,(P)}$ at s_j and $\Psi_{j,(B\setminus P)}$ at t_j, which is where the potential goes as the scales of P grow and those of $B\setminus P$ fall. Proposition 49.27 is one table and is unchanged.

50.49 Receipts

The identities below were checked on small families before or after they were written; the checks are receipts, not part of any proof.

50.49.1 Chapters 35 to 46

In exact rational arithmetic at $(a,b)=(\frac{7}{3},\frac{5}{4})$, with two linear letters of rational coefficients and the exponents $\frac{9}{7}$ and $-\frac{2}{3}$, and at $r=3$: the expansion of $L\,x(1-x)\,\partial_x g + A_n g$ at $g=(-1)^r\Pi_r^{a,b}$ in the Beta ports had no component below the order $r-h-1$, and its coefficient of the order $r+h+1$ matched Theorem 35.15. At $(n,k,r)\in\{(2,3,1),(2,3,2),(1,4,3),(2,5,1)\}$ the column sums $C_{n,k}(P_r)$, read off the Laurent expansions of the share functions, matched the sums of the proof of Theorem 37.19, the signs $(-1)^{jk}$ included, and $C_{n,k-1}(P_r)+2\,(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,n+r])\,C_{n,k}(P_r)$ was rational. For two letters at $\kappa=0.7$, $\mathbf{w}=(0.4,0.5)$, $\boldsymbol{\xi}=(1,1+i)$, $G=e^{-\rho}$, $C_1=1+\rho$ and $C_2=2+\rho^2$, the quantity $\big(\int_0^\infty\cdots d\rho - A(0)\big)\lambda^{-\kappa^\flat}$ of Proposition 38.23 was $4.10646-0.33755i$, $4.10314-0.33828i$ and $4.10276-0.33837i$ at $\lambda=10^{-3},10^{-4},10^{-5}$, against $B(0)=4.10272-0.33838i$.

50.49.2 Chapters 17 and 49

On four marks, with the tables $\binom{\mathcal{E}}{2}$, the rank-two table with one parallel pair, the direct sum of two rank-one tables and a rank-three table with a coloop, all with random weights: the identity of Proposition 17.4(i) held to 10^{-13} at random tilts and random questions with exponents of both signs, and the two forms of the wall at a tilt agreed to 10^{-13}; the period computed on the sectors agreed with a direct cubature of the tilt integral to 10^{-8}; $\lambda^3 P_F(\lambda q)$ approached $\sum_\pi \prod_k \kappa_{U_k}^{-1} = 1.87097$, and $(\sum_\pi \prod_k \kappa_{U_k}^{-1} - \lambda^3 P_F(\lambda q))/\lambda$ approached $\sum_\pi \prod_k \kappa_{U_k}^{-1} \sum_j (s_j \log\theta_{j,T^+_{j,\pi}} + t_j \log\theta_{j,T^-_{j,\pi}}) = 2.75547$ (2.7548 at $\lambda = 3\cdot 10^{-4}$). On three marks with three tables: the relative error of Theorem 17.5(ii) times $|\lambda|$ was 0.172–0.184 along $\lambda\in\{2,\dots,40\}$ and along $\lambda=2+i\eta$, $\eta\in\{5,10\}$, the same constant in both directions; the usage at the computed native gauge equalled the masses; and the local slopes of $\log\mathbb{P}(\pm Y>x)$ for an odd statistic at the centre were between -1.4985 and -1.5014 against $-\ell^*_{\boldsymbol{\sigma}}(c,\mathbf{b})=-1.5$. In exact rational arithmetic, on four marks with sample sizes $\mathbf{s}=(1,0,1,0)$, $\mathbf{t}=(0,1,1,1)$: the conditional law of a sample given its counts was $\theta_{\text{draws}}/\Theta_F(\mathbf{m})$, and the law of the wall κ_S was $\prod_j \mathsf{Q}^{K}_{j,S}{}^{s_j}\mathsf{Q}^{\Psi}_{j,S}{}^{t_j}$ for every S. The total of Theorem 49.25 matched $\iota_B^{\mathbf{E}}+\iota_B^{\mathbf{O}}$ to 10^{-12} for $|B|=2$ in three tables, and to 10^{-10} for $|B|=3$, a Hamiltonian path of K_4 in the graphic table of K_4 together with $\binom{\mathcal{E}}{3}$ on six marks; the relation $\iota_B^*(z_R)=(-1)^{|B|}\iota_B(-z_R)$ held to 10^{-12} in each table. All of these were rerun on 20 October 2026 and reproduced (the cubature for $|B|=2$ on a grid of 1601 points a side, matching to $6\cdot 10^{-13}$).

In exact rational arithmetic, on six marks with two weighted graphic tables of K_4 and a weighted $\binom{\mathcal{E}}{3}$, at the exponents $(2,1)$, $(1,3)$, $(0,2)$, a rational gauge and the bunch B of a Hamiltonian path: for every $A\subseteq B$ with $|A|\geq 2$ the coefficient λ_A of Proposition 49.24(ii) satisfied $e^{\lambda_A}=e^{\iota_A^{\mathbf{E}}+\iota_A^{\mathbf{O}}}$ exactly, the right side computed from the deletions and contractions of $B\setminus A$ themselves.

Part XI

Exercises

Each exercise is a computation on a particular list, table or ray, set as a guided example. Its solution follows the procedures and theorems of the chapters step by step: every step names the statement it uses, and every quantity that the next step needs is displayed, in exact arithmetic. A step that is a machine computation too large to display is given by its exact input, its method, the output that the next step uses, the check that was run on it, and the receipt that reproduces it. Decimal values appear only as renderings of exact ones.

Lists are named by an upright capital with the number of marks as a subscript, and each is defined by its marks and bases where it first appears.

Chapter 51

Exercises on tables, families and classification

The exercises of this chapter work the statements of Parts II and III, and the first statements of the reading of rays, on particular lists. The list on two marks is opened on its share side and read along its centre ray, where its values, its closings and the matrix of its branch fit together exactly. The pins of the atom formula of six uniform lists have the elementary divisors 1, and two of them still pin some shares at fractions. Four Foreman trees are drawn: one that is an atom at every lean, one that peels at a bunch of width one into a cell whose contraction is the dual of its deletion, and one whose Foreman bunch at a lean has width two and whose sets do not split off at the centre. Along a set of width two the Skeleton values are shown not to be rational functions of the point, and a family with exponents of both signs is peeled with and without its record. Every number displayed is exact; the receipts that recompute them are the scripts named in each solution.

51.1 The list on two marks

Exercise 51.1 (The list $\binom{[2]}{1}$ on its share side)**.** Let $\mathcal{E} = \{1, 2\}$ and $F = \big(\binom{\mathcal{E}}{1}; s, t\big)$, the list whose bases are the two singletons, with $\operatorname{Re} s, \operatorname{Re} t > 0$ and masses $\mathbf{m} = (m_1, m_2)$ on the balance wall with $\operatorname{Re} m_1, \operatorname{Re} m_2 > 0$.

(i) Write the atom formula of $P_F(\mathbf{m}; s, t)$ (Corollary 18.16): its shares, its pins, its fibre and its measure, and close it.

(ii) At $(\mathbf{1}; 1, 1)$ find the integrand on the line $\operatorname{Re} a = \frac{1}{2}$ and the period.

Solution. Receipt: `ex01_share_side.py`.

(i) *The letters.* The bases are $T_1 = \{1\}$ and $T_2 = \{2\}$, so (Definition 7.1)

$$K(\alpha) = \alpha^{T_1} + \alpha^{T_2} = \alpha_1 + \alpha_2, \qquad \Psi(\alpha) = \alpha^{\mathcal{E}\setminus T_1} + \alpha^{\mathcal{E}\setminus T_2} = \alpha_2 + \alpha_1,$$

the rank and the corank are 1, and the balance wall is $\kappa_{\mathcal{E}} = m_1 + m_2 - (s + t) = 0$ (Definition 8.1), with the strength $\sigma = \frac{s+t}{2}$ and the offset $\mu_1 = m_1 - \sigma$.

The shares and the pins. Corollary 18.16, with $g = 2$, opens each letter with one share per basis: a_1, a_2 for K, a_i the share of α^{T_i}, and b_1, b_2 for Ψ, b_i the share of $\alpha^{\mathcal{E}\setminus T_i}$. Its pins are the two letter totals and the odd load at the mark 1 (Definition 12.24), with $\chi_{T_1}(1) = 1$ and $\chi_{T_2}(1) = -1$:

$$a_1 + a_2 = s, \qquad b_1 + b_2 = t, \qquad \tfrac{1}{2}(a_1 - b_1) - \tfrac{1}{2}(a_2 - b_2) = m_1 - \tfrac{s+t}{2}.$$

With $a = a_1$ they give

$$a_2 = s - a, \qquad b_1 = a + t - m_1, \qquad b_2 = m_1 - a,$$

and the load at the mark 1, $a_1 + b_2$, is m_1, as $\mathrm{load}_1 = \sigma + \langle \boldsymbol{\delta} \rangle_1$ requires (Definition 12.24). The weights are 1, so the factor $\prod_T \theta_T^{-a_T - b_T}$ is 1, and the fibre has the dimension $4 - 3 = 1$.

The measure. The matrix of the pins, the shares in the order (a_1, a_2, b_1, b_2), and its Gram matrix are

$$P = \begin{pmatrix} 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \\ \frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} & \frac{1}{2} \end{pmatrix}, \qquad PP^{\mathsf{T}} = \mathrm{diag}(2, 2, 1), \qquad \sqrt{\det PP^{\mathsf{T}}} = 2,$$

and the fibre runs along $(1, -1, 1, -1)$, of length 2: the imaginary part y of a moves the point by the volume $2\,dy$. So the fibre integral of Definition 4.1 is $(2\pi)^{3-4} \cdot \frac{1}{2} \cdot 2 \int dy = \frac{1}{2\pi i} \int da$:

$$P_F(\mathbf{m}; s, t) = \frac{1}{2\pi i} \int_{(c)} \Gamma_{\substack{2 \\ 1}} \begin{bmatrix} a, & s - a \\ & s \end{bmatrix} \Gamma_{\substack{2 \\ 1}} \begin{bmatrix} a + t - m_1, & m_1 - a \\ & t \end{bmatrix} da,$$

on a line $\mathrm{Re}\, a = c$ on which all four shares have positive real parts, $\max(0, \mathrm{Re}(m_1 - t)) < c < \min(\mathrm{Re}\, s, \mathrm{Re}\, m_1)$; such lines exist, since $\mathrm{Re}\, s, \mathrm{Re}\, t, \mathrm{Re}\, m_1 > 0$ and $\mathrm{Re}(m_1 - t) < \mathrm{Re}\, s$ is $\mathrm{Re}\, m_2 > 0$.

The closing. The integrand is $\Gamma(a)\,\Gamma(t - m_1 + a)\,\Gamma(s - a)\,\Gamma(m_1 - a)$ over $\Gamma(s)\Gamma(t)$: four Gammas on a line that separates the poles of the first two from those of the last two. Corollary 4.7, with its four entries 0, $t - m_1$, s, m_1 and the variable a, adds them in pairs, $0 + s$, $(t - m_1) + m_1$, $0 + m_1$ and $(t - m_1) + s = m_2$:

$$\frac{1}{2\pi i} \int_{(c)} \Gamma(a)\,\Gamma(t - m_1 + a)\,\Gamma(s - a)\,\Gamma(m_1 - a)\,da = \Gamma_{\substack{4 \\ 1}} \begin{bmatrix} s, & t, & m_1, & m_2 \\ & & s + t & \end{bmatrix}.$$

Dividing by $\Gamma(s)\Gamma(t)$ (Proposition 1.3(i),(ii)),

$$P_F(\mathbf{m}; s, t) = \Gamma_{\substack{2 \\ 1}} \begin{bmatrix} m_1, & m_2 \\ m_1 + m_2 & \end{bmatrix}.$$

This agrees with the period read on the simplex (Theorem 8.7): there $K = \Psi = u_1 + u_2 = 1$, and the period is the shape integral $\int_{\Delta_\mathcal{E}} u^{\mathbf{m}-\mathbf{1}} d\omega_\mathcal{E} = \Gamma_{\substack{2 \\ 1}} \begin{bmatrix} m_1, & m_2 \\ m_1 + m_2 & \end{bmatrix}$ (Theorem 3.9).

(ii) At $(\mathbf{1}; 1, 1)$, $m_1 = s = t = 1$, and the shares are $a_1 = b_1 = a$ and $a_2 = b_2 = 1 - a$: the basis share and the cobasis share of each basis are equal. By Proposition 1.3(i),(v) the integrand is

$$\Gamma_{\substack{2 \\ 1}} \begin{bmatrix} a, & 1 - a \\ & 1 \end{bmatrix} \Gamma_{\substack{2 \\ 1}} \begin{bmatrix} a, & 1 - a \\ & 1 \end{bmatrix} = \Gamma_{\substack{4 \\ 0}} \big[a,\ a,\ 1 - a,\ 1 - a\big] = \Big(\frac{\pi}{\sin \pi a}\Big)^2,$$

regular on $0 < \mathrm{Re}\, a < 1$. On $a = \frac{1}{2} + iy$, where $\sin \pi a = \cosh \pi y$,

$$\frac{1}{2\pi i} \Gamma_{\substack{4 \\ 0}} \big[a,\ a,\ 1 - a,\ 1 - a\big]\ da = \frac{\pi}{2 \cosh^2 \pi y}\, dy = \frac{2\pi}{(e^{\pi y} + e^{-\pi y})^2}\, dy = p_{\mathrm{crit}}(y)\, dy,$$

the density of the critical-line law (Definition 36.1). Its primitive is $\frac{1}{2} \tanh \pi y$, which runs from $-\frac{1}{2}$ to $\frac{1}{2}$, so its integral is 1; and (i) gives the same, $P_F(\mathbf{1}; 1, 1) = \Gamma_{\substack{2 \\ 1}} \begin{bmatrix} 1, & 1 \\ & 2 \end{bmatrix} = 1$ (Theorem 36.2).

Answer. The atom formula is the integral over one share

$$P_F(\mathbf{m};s,t)=\frac{1}{2\pi i}\int_{(c)}\Gamma_{\,1}^{2}\!\begin{bmatrix}a,\ s-a\\ s\end{bmatrix}\Gamma_{\,1}^{2}\!\begin{bmatrix}a+t-m_1,\ m_1-a\\ t\end{bmatrix}da=\Gamma_{\,1}^{2}\!\begin{bmatrix}m_1,\ m_2\\ m_1+m_2\end{bmatrix}.$$

At $(\mathbf{1};1,1)$ its integrand on the line $\operatorname{Re}a=\frac12$ is $\Gamma_{\,0}^{4}\big[a,\ a,\ 1-a,\ 1-a\big]=\pi^2/\cosh^2\pi y$, the density of the critical-line law times 2π, and the period is 1. □

Exercise 51.2 (The centre ray of $\binom{[2]}{1}$)**.** For the centre ray of the list $\binom{\mathcal{E}}{1}$, $\mathcal{E}=\{1,2\}$, at the strength 1 (Definition 38.13):

(i) find its stride, its native gauge and native value, its values $\langle1\rangle_k$ and a recurrence of order one that they satisfy, and the integrand of the atom formula at step k against the one at step 1;

(ii) find its closings $\mathsf{C}_j(1)$ (Definition 39.30) and the volume V_1 of its direction, and check Proposition 39.34 and the reflected recurrence at every j;

(iii) find the matrix H of Theorem 38.15 and show that $k\,\langle1\rangle_k\,\mathsf{C}_k(1)=2=(\det H)^{-1}$ for every $k\ge1$; compare with the leading terms of Theorems 38.6 and 39.57.

Solution. Receipt: `ex01_share_side.py`.

(i) *Stride and native gauge.* Definition 38.13 with one table and $\sigma_1=1$ gives the origin 0 and the direction $(\mathbf{1};1,1)$; on the chart $\alpha_2=1$, with $x=\alpha_1$,

$$f=\frac{\alpha^{\mathbf{1}}}{K\Psi}=\frac{\alpha_1\alpha_2}{(\alpha_1+\alpha_2)^2}=\frac{x}{(1+x)^2}.$$

The gauge $\mathbf{1}$ is native (Proposition 8.21(i)), and $f\le f(\mathbf{1})=\frac14$ on the orthant with equality only at $x=1$ (Theorem 38.14(i)): the native value of the direction is $\frac14$.

Values. By Definition 38.13, $\langle1\rangle_k=P_F(k\mathbf{1};k,k)$, which Exercise 51.1(i) at $m_1=m_2=s=t=k$ gives:

$$\langle1\rangle_k=\Gamma_{\,1}^{2}\!\begin{bmatrix}k,\ k\\ 2k\end{bmatrix}=\frac{((k-1)!)^2}{(2k-1)!}:\qquad 1,\ \tfrac16,\ \tfrac{1}{30},\ \tfrac{1}{140},\ \tfrac{1}{630},\ \tfrac{1}{2772}\quad(k=1,\dots,6).$$

By the shift (Proposition 1.3(iii)) $\langle1\rangle_{k+1}/\langle1\rangle_k=k^2/\big(2k(2k+1)\big)=k/\big(2(2k+1)\big)$, the ratios $\frac16,\frac15,\frac{3}{14},\frac29,\frac{5}{22}$, so

$$2(2k+1)\,\langle1\rangle_{k+1}-k\,\langle1\rangle_k=0,$$

a recurrence of order one. Its symbol, read off the coefficients of k, is $4\lambda-1$, which vanishes at the native value $\frac14$, as Proposition 38.9 requires; and the ratios tend to $\frac14$.

The integrand at step k. At $m_1=s=t=k$ the shares of Exercise 51.1(i) are $a_1=b_1=a$ and $a_2=b_2=k-a$, and the integrand is $\Gamma(a)^2\Gamma(k-a)^2/\Gamma(k)^2$. The shift applied $k-1$ times to $\Gamma(k-a)$ and to $\Gamma(k)$ gives

$$\Gamma_{\,2}^{4}\!\begin{bmatrix}a,\ a,\ k-a,\ k-a\\ k,\ k\end{bmatrix}=\Gamma_{\,0}^{4}\big[a,\ a,\ 1-a,\ 1-a\big]\left(\frac{(1-a)(2-a)\cdots(k-1-a)}{(k-1)!}\right)^2:$$

at $k=2,3,4$ the factor is $(a-1)^2$, $\frac14(a-1)^2(a-2)^2$ and $\frac{1}{36}(a-1)^2(a-2)^2(a-3)^2$. The step multiplies the kernel of step 1 by the square of a polynomial in the share, which adds zeros at $a=1,\dots,k-1$ and no poles; the values are rational numbers.

(ii) *Closings.* The origin is integral and both letters have the exponent 1 in the direction, so Definition 39.30 applies, with $\omega_0/dy = 1$ and $\mathsf{C}_j(1) = \mathrm{CT}(f^{-j})$ (Corollary 39.36). On the chart $f^{-j} = x^{-j}(1+x)^{2j}$, whose constant term is the coefficient of x^j in $(1+x)^{2j}$:

$$\mathsf{C}_j(1) = \binom{2j}{j}: \qquad 1,\ 2,\ 6,\ 20,\ 70,\ 252,\ 924,\ 3432 \quad (j = 0, \dots, 7).$$

The volume. The two orders of $\mathcal{E}$ have the tails $U_2 = \{2\}$ and $U_2 = \{1\}$, and the direction walls are $\kappa_{1,\{e\}} = \sigma_1 c(\{e\}) = 1$ (Proposition 8.21(ii); $c(\{e\}) = r(\{e\}) + r(\mathcal{E} \setminus \{e\}) - r = 1$ by Definition 7.12 and Theorem 7.13). So $V_1 = 1 + 1 = 2$ (Proposition 39.34).

The principal parts. $\langle 1 \rangle_k = \Gamma(k)^2/\Gamma(2k)$ continues meromorphically in k. At $k = -j$, $j \in \mathbb{N}$, the residues of Proposition 1.3(iv) give $\Gamma(k) = \frac{(-1)^j}{j!}(k+j)^{-1} + O(1)$ and, the pole of Γ at $2k = -2j$ having the residue $\frac{1}{(2j)!}$, $\Gamma(2k) = \frac{1}{2(2j)!}(k+j)^{-1} + O(1)$. So the pole has order $1 = n - 1$ and

$$\lim_{k \to -j} (k+j)\, \langle 1 \rangle_k = \frac{(j!)^{-2}}{(2(2j)!)^{-1}} = 2\binom{2j}{j} = V_1\, \mathsf{C}_j(1): \qquad 2,\ 4,\ 12,\ 40,\ 140,\ 504 \quad (j = 0, \dots, 5),$$

Proposition 39.34 at every j.

The reflected recurrence. Corollary 39.60 reads the recurrence of (i), $p_0(k) = -k$ and $p_1(k) = 2(2k+1)$, at $k = -j$ on the closings: $j\, \mathsf{C}_j(1) + 2(1-2j)\, \mathsf{C}_{j-1}(1) = 0$, that is $\mathsf{C}_j(1) = \frac{2(2j-1)}{j}\, \mathsf{C}_{j-1}(1)$ for $j \geq 1$, which $\binom{2j}{j}$ satisfies; at $j = 0$ the sum is $p_0(0)\, \mathsf{C}_0(1) = 0$, as in Corollary 39.36.

(iii) *The matrix H.* In Theorem 38.15, $\alpha^\star = \mathbf{1}$, $e_0 = 2$, and $s_{11} = t_{11} = 1$, so H is the 1×1 matrix $\kappa_{\mathbf{1}}(X_1, X_1) + \kappa_{\mathbf{1}}(X_1, X_1)$, the cobasis law at $(\alpha^\star)^{-1} = \mathbf{1}$ being the weight law (Theorem 7.16). Under the weight law, uniform on $\{1\}, \{2\}$ (Definition 7.17), X_1 is 1 with the probability $\frac{1}{2}$ and has the variance $\frac{1}{4}$; so $H = \frac{1}{2}$. Directly: $-\log f = 2\log(1 + e^y) - y$ on the chart $x = e^y$, with the second derivative $2e^y/(1+e^y)^2 = \frac{1}{2}$ at $y = 0$.

The product. For every $k \geq 1$,

$$k\, \langle 1 \rangle_k\, \mathsf{C}_k(1) = k\, \frac{((k-1)!)^2}{(2k-1)!} \cdot \frac{(2k)!}{(k!)^2} = k \cdot \frac{2k}{k^2} = 2 = (\det H)^{-1}.$$

The leading terms. The native gauge $\mathbf{1}$ is nondegenerate (Theorem 39.57), and near it $\log f = \log \frac{1}{4} - \frac{1}{2}v^2$ with $v = H^{1/2}y + O(y^2)$, so $(\omega_0/dv)(\mathbf{1}) = (dy/dv)(0) = H^{-1/2} = \sqrt{2}$. Theorem 38.6(i) gives $\langle 1 \rangle_k \sim 4^{-k} k^{-1/2} a_0(1)$ with $a_0(1) = (2\pi)^{1/2}\sqrt{2} = 2\sqrt{\pi}$, and Theorem 39.57, in which $\hat{A}_\star(1)$ is that expansion divided by $f(\mathbf{1})^k k^{-1/2} = 4^{-k} k^{-1/2}$, with the leading term $a_0(1)$, gives $\mathsf{C}_j(1) \sim 4^j j^{-1/2} (2\pi)^{-1} 2\sqrt{\pi} = 4^j (\pi j)^{-1/2}$. Their product at $j = k$ is $k^{-1}\, a_0(1)^2/(2\pi) = 2k^{-1}$ to the leading order, $(\det H)^{-1} k^{-(n-1)}$; here the product is $2k^{-1}$ exactly, at every k.

Answer. The stride is $\alpha_1\alpha_2/(\alpha_1 + \alpha_2)^2$, with the native gauge $\mathbf{1}$ and the native value $\frac{1}{4}$; the values are $\langle 1 \rangle_k = \Gamma \begin{bmatrix} k,\ k \\ 2k \end{bmatrix}_1^2$, with $2(2k+1)\langle 1 \rangle_{k+1} = k \langle 1 \rangle_k$, and the integrand at step k is the one at step 1 times $\big((1-a)_{k-1}/(k-1)!\big)^2$. The closings are $\mathsf{C}_j(1) = \binom{2j}{j}$, $V_1 = 2$, and $\lim_{k \to -j}(k+j)\langle 1 \rangle_k = 2\binom{2j}{j}$ at every j. $H = \frac{1}{2}$, and $k\, \langle 1 \rangle_k\, \mathsf{C}_k(1) = 2 = (\det H)^{-1}$ at every $k \geq 1$. □

51.2 The pins of the atom formula

Exercise 51.3 (The pins of the atom formula of six lists)**.** For a list $(\mathcal{E}, \mathcal{B})$ on n marks at data on the balance wall, the atom formula (Corollary 18.16) is a fibre integral over the shares a_T, b_T,

$T \in \mathcal{B}$, pinned by $|\mathbf{a}| = s$, $|\mathbf{b}| = t$ and $\langle \boldsymbol{\delta} \rangle_e = \mu_e$ for $e \neq g$. For the six lists $\binom{[2]}{1}$, $\binom{[3]}{1}$, $\binom{[3]}{2}$, $\binom{[4]}{2}$, $\binom{[4]}{3}$ and $\binom{[5]}{2}$, with $g = n$:

(i) write the pins with integer coefficients;

(ii) find the elementary divisors of their matrix;

(iii) decide for which of the six lists, at integer data, every point of the fibre at which the shares outside $n+1$ shares with independent columns are integers has all its shares integers, and for the others give such a point with a share that is not an integer.

Solution. Receipt: `ex02_pins.py`.

(i) By Definition 12.24 the load at a mark is $\text{load}_e = \sum_{T \ni e} a_T + \sum_{T \not\ni e} b_T = \sigma + \langle \boldsymbol{\delta} \rangle_e$, with $\sigma = \frac{1}{2}(|\mathbf{a}| + |\mathbf{b}|)$. So, with the two letter totals, the pins $\langle \boldsymbol{\delta} \rangle_e = \mu_e$ are the pins $\text{load}_e = m_e$, $e \neq g$, which have the coefficients 0 and 1. Passing from the one set of rows to the other adds to the row of e half the sum of the two rows of the totals: a triangular change with determinant 1, which leaves the delta function of Definition 4.1, and so the fibre integral, unchanged. The matrix of the pins, M, has $n+1$ rows, the two totals and the loads at $e \neq g$, and $2|\mathcal{B}|$ columns:

$$\text{column of } a_T: \ \big(1,\ 0,\ (\mathbf{1}_T(e))_{e \neq g}\big), \qquad \text{column of } b_T: \ \big(0,\ 1,\ (\mathbf{1}_{\mathcal{E} \setminus T}(e))_{e \neq g}\big).$$

(ii) An integer matrix of rank ρ has integer matrices U, V of determinant ± 1 with UMV diagonal, with the entries $d_1 \mid d_2 \mid \cdots \mid d_\rho$ and zeros, and $d_1 \cdots d_k$ is the greatest common divisor of the $k \times k$ minors of M (the Smith normal form of an integer matrix, which applies here because the pins have integer coefficients). So the elementary divisors are all 1 as soon as one maximal minor is ± 1, which also gives the rank $n+1$. With the rows in the order (total of K, total of Ψ, loads at $1, \ldots, n-1$), these minors are ± 1:

$\binom{[2]}{1}$, (a_1, a_2, b_1)

$$\begin{pmatrix} 1 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}$$

$\det = 1$

$\binom{[3]}{1}$, (a_1, a_2, a_3, b_1)

$$\begin{pmatrix} 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 \end{pmatrix}$$

$\det = 1$

$\binom{[3]}{2}$, $(a_{12}, a_{13}, a_{23}, b_{12})$

$$\begin{pmatrix} 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \end{pmatrix}$$

$\det = -1$

$\binom{[4]}{3}$, $(a_{123}, a_{124}, a_{134}, a_{234}, b_{123})$

$$\begin{pmatrix} 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 & 0 \\ 1 & 1 & 0 & 1 & 0 \\ 1 & 0 & 1 & 1 & 0 \end{pmatrix}$$

$\det = -1$

$\binom{[4]}{2}$, $(a_{12}, a_{13}, a_{14}, a_{23}, b_{12})$

$$\begin{pmatrix} 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 \end{pmatrix}$$

$\det = 1$

$\binom{[5]}{2}$, $(a_{12}, a_{13}, a_{14}, a_{15}, a_{23}, b_{12})$

$$\begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 \end{pmatrix}$$

$\det = -1$

So every elementary divisor is 1 for the six lists; the receipt computes the Smith normal forms, $\text{diag}(1, \ldots, 1)$ in each case. Then $UMV = (I \mid 0)$: for every integer right side $(s, t, (m_e)_{e \neq g})$ the pins have integer solutions, and the integer points of the fibre form a translate of the integer vectors of the kernel of M, a lattice of rank $2|\mathcal{B}| - n - 1$, the dimension of the fibre.

(iii) Fix a set J of $n+1$ shares whose columns have the minor $\det M_J \neq 0$, and give the other shares integer values. The pins then fix the shares of J by Cramer's rule, with the denominator $\det M_J$. The absolute values of all maximal minors, with their numbers, are

	0	1	2	3
$\binom{[2]}{1}$	0	4	0	0
$\binom{[3]}{1}$, $\binom{[3]}{2}$	3	12	0	0
$\binom{[4]}{3}$	24	32	0	0
$\binom{[4]}{2}$	288	480	24	0
$\binom{[5]}{2}$	17940	19170	1620	30

so for $\binom{[2]}{1}$, $\binom{[3]}{1}$, $\binom{[3]}{2}$ and $\binom{[4]}{3}$ every such point at integer data has integer shares. For $\binom{[4]}{2}$ the minor on $(a_{12}, a_{34}, b_{13}, b_{14}, b_{24})$ is

$$\det \begin{pmatrix} 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 \\ 1 & 0 & 0 & 0 & 1 \\ 1 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 \end{pmatrix} = 2,$$

and at the centre $(\mathbf{1}; 1, 1)$ with the other seven shares 0 the pins $a_{12} + a_{34} = 1$, $b_{13} + b_{14} + b_{24} = 1$, $a_{12} + b_{24} = 1$ (the load at 1), $a_{12} + b_{13} + b_{14} = 1$ (at 2) and $a_{34} + b_{14} + b_{24} = 1$ (at 3) give

$$a_{12} = a_{34} = b_{13} = b_{24} = \tfrac{1}{2}, \qquad b_{14} = 0.$$

For $\binom{[5]}{2}$ the minor on $(a_{12}, a_{13}, a_{45}, b_{14}, b_{15}, b_{23})$ is

$$\det \begin{pmatrix} 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & 1 \end{pmatrix} = -3,$$

and at the centre $(\mathbf{1}; 1, 1)$ with the other fourteen shares 0 the pins give $a_{12} = a_{13} = a_{45} = b_{14} = b_{15} = b_{23} = \frac{1}{3}$: every total and every load is $3 \cdot \frac{1}{3} = 1$.

Answer. The pins are the two letter totals and the loads $\mathrm{load}_e = m_e$, $e \neq g$, a 0/1 matrix with $n+1$ rows and $2|\mathcal{B}|$ columns. For all six lists its elementary divisors are 1: at integer data the integer points of the fibre form a lattice of full rank in it. For $\binom{[2]}{1}$, $\binom{[3]}{1}$, $\binom{[3]}{2}$ and $\binom{[4]}{3}$ every maximal minor is 0 or ± 1, and every point with integer shares outside $n+1$ independent ones has integer shares. For $\binom{[4]}{2}$ and $\binom{[5]}{2}$ some maximal minors are ± 2, and ± 3 for $\binom{[5]}{2}$, and at the integer data $(\mathbf{1}; 1, 1)$ the points displayed have the seven, respectively fourteen, shares outside such a minor at the integer 0 and shares $\frac{1}{2}$, respectively $\frac{1}{3}$, on it. So the pins of these two atom formulas are not unimodular in the sense of the paragraph after Theorem 20.59: a closing (Theorem 4.5) that pins the shares outside such a minor at poles of their Gammas can reach shares that are not integers, even at integer data, although the elementary divisors are 1. □

51.3 Foreman trees

Exercise 51.4 (The Foreman trees of $\binom{[4]}{1}$)**.** Let $F = \big(\binom{[4]}{1}; s, t\big)$, the list on $\mathcal{E} = \{1,2,3,4\}$ whose bases are its singletons, read at its realizations $\Upsilon_{\sigma,\delta;\mathbf{1}}$ at the table's gauge, $s = \sigma + \delta$, $t = \sigma - \delta$ (Definition 9.1). Find its classes at the centre and at every lean, and its three Foreman trees (Theorem 14.6).

Solution. Receipt: `ex03_tree_u14.py`.

The letters and the molecule. $K = \alpha_1+\alpha_2+\alpha_3+\alpha_4$ and $\Psi = \alpha_1\alpha_2\alpha_3+\alpha_1\alpha_2\alpha_4+\alpha_1\alpha_3\alpha_4+\alpha_2\alpha_3\alpha_4$ (Definition 7.1). Every nonempty S has $r(S) = 1$, so every proper nonempty S has $c(S) = r(S)+r(\mathcal{E}\setminus S)-1 = 1 > 0$ (Definition 7.12, Theorem 7.13): the family is connected (Definition 8.1) and one molecule.

The masses. Each mark lies in one of the four bases, so the occupation at the table's gauge is $R_e(\mathbf{1}) = \frac{1}{4}$ (Theorem 7.16), and Proposition 9.3 gives the realization $\Upsilon_{\sigma,\delta;\mathbf{1}}$ the masses

$$\tau_e = \sigma + \delta\big(2 \cdot \tfrac{1}{4} - 1\big) = \sigma - \tfrac{\delta}{2} \qquad \text{at every mark,}$$

with the total $4\sigma - 2\delta = s \cdot 1 + t \cdot 3$, on the balance wall.

The writings. By Proposition 10.2, for a mark e and an order $\mathbf{g} = (g_1, g_2, g_3)$ of its room, the pattern of the basis $\{h\}$ is the position of h, and at the table's gauge each pattern of one position has the weight 1:

$$K_{e,\mathbf{g}}(x) = x_0 + x_1 + x_2 + x_3, \qquad \Psi_{e,\mathbf{g}}(x) = x_1x_2x_3 + x_0x_2x_3 + x_0x_1x_3 + x_0x_1x_2,$$

the same two polynomials for every mark and every order (the receipt finds one pair among the $4 \cdot 6$ writings). So one pair of functions, $\Phi^{\mathbf{E}}_{e,\mathbf{g}} = \sigma \log(K_{e,\mathbf{g}}\Psi_{e,\mathbf{g}})$ and $\Phi^{\mathbf{O}}_{e,\mathbf{g}} = \delta \log(K_{e,\mathbf{g}}/\Psi_{e,\mathbf{g}})$ with $x_i = e^{v_i}$, is written from every mark. With no partner, the reading of e (Definition 10.1 at $k = 0$) is the pair of $K = e^v + 3$ and $\Psi = 3e^v + 1$ at every mark.

The classes. By Proposition 10.4 the reading is constant on $\mathcal{E}$ at every lean δ, the centre included: $\mathrm{Cl}(\Upsilon_{\sigma,\delta;\mathbf{1}}) = \{\mathcal{E}\}$. Corollary 11.16 says the same: all 24 permutations of $\mathcal{E}$ carry the table, mapping singletons to singletons, and they take every mark to every other; none exchanges it, a basis having one mark and a cobasis three.

The trees. Every realization is atomic (Definition 10.1), so by Definition 14.4 the molecule is an atom and its Foreman tree is that one leaf, with no bunch and no peel. Theorem 14.6 gives the list at its one pair the three trees $\mathrm{Tree}(F;\sigma,0)$ and $\mathrm{Tree}(F;\sigma,\pm\delta)$, and each is this atom. The molecule answers yes and the label is $(1,1)$ (Definition 11.7).

Answer. At the centre and at every lean the one class is $\mathcal{E}$; the three Foreman trees of $\binom{[4]}{1}$ are one atom, with no bunch. □

Exercise 51.5 (A tree that peels at a bunch of width one)**.** Let P_5 be the list on $\{1,\dots,5\}$ whose bases are the nine pairs other than $\{1,2\}$, read at its realizations $\Upsilon_{\sigma,\delta;\mathbf{1}}$. Find its classes and its Foreman bunch at the centre and at a lean, the width of the bunch, its patterns with their probabilities and children, its record and its peel, and its three Foreman trees. Write P_5 as a substitution through the two cells of Theorem 19.4, and show that the contraction of the cell of the room is the dual of its deletion.

Solution. Receipt: `ex04_five_marks.py`.

The letters. With e_k the elementary symmetric polynomials of α, the rank is 2, the corank 3, and

$$K = e_2(\alpha) - \alpha_1\alpha_2, \qquad \Psi = e_3(\alpha) - \alpha_3\alpha_4\alpha_5.$$

The classes. A bijection of the marks carries P_5 exactly when it maps the one pair that is not a basis, $\{1,2\}$, to itself: these are the 12 products of a permutation of $\{1,2\}$ and one of $\{3,4,5\}$, with the orbits $\{1,2\}$ and $\{3,4,5\}$. No bijection exchanges P_5, a basis having two marks and a cobasis three. By Corollary 11.16 the classes at the centre and at every lean are

$$\mathrm{Cl} = \big\{\{1,2\},\ \{3,4,5\}\big\}.$$

The occupations confirm the split at the centre: $R_1(\mathbf{1}) = R_2(\mathbf{1}) = \frac{3}{9} = \frac{1}{3}$ and $R_3(\mathbf{1}) = R_4(\mathbf{1}) = R_5(\mathbf{1}) = \frac{4}{9}$, and two marks of one class at the centre have equal or complementary occupations (Proposition 10.9(ii)), while $\frac{4}{9} \notin \{\frac{1}{3}, \frac{2}{3}\}$.

The Foreman bunch. By Definition 13.6 the Foreman bunch at the centre is the class with the fewest marks, $B = \{1,2\}$; at a lean the key $(|C|, |C^\circ|, C^\circ, C)$ is least at $C = \{1,2\}$, of two marks, so $B(\mathrm{P}_5; \sigma, \pm\delta) = \{1,2\}$ as well. Its window is $\{0,1\}$ (a basis meets B in at most one mark, and $\{3,4\}$ avoids it), so $d(B) = 0$, $r(B) = 1$ and

$$c(B) = r(B) + r(R) - r = 1 + 2 - 2 = 1$$

(Definition 7.12, Theorem 7.13), $R = \{3,4,5\}$; no basis contains both of its marks, so B is a parallel bunch (Definition 19.1).

Patterns, probabilities, children. The patterns of B are $\varnothing$, $\{1\}$, $\{2\}$ (Definition 12.1), each the trace of three of the nine bases, so each has the probability $\pi_p(\mathbf{1}) = \frac{1}{3}$ at the table's gauge (Definition 12.25). The children on R are

$$\mathcal{B}_{(\varnothing)} = \{34, 35, 45\} = \binom{R}{2}, \qquad \mathcal{B}_{(\{1\})} = \mathcal{B}_{(\{2\})} = \{3,4,5\} = \binom{R}{1},$$

with $K_{\binom{R}{2}} = e_2(\alpha_R)$, $\Psi_{\binom{R}{2}} = e_1(\alpha_R)$, $K_{\binom{R}{1}} = e_1(\alpha_R)$ and $\Psi_{\binom{R}{1}} = e_2(\alpha_R)$.

Record and peel. The record (Definition 14.2) is the three indexed children $\big(p; \mathcal{B}_{(p)}; \frac{s}{3}, \frac{t}{3}\big)$, $p = \varnothing, \{1\}, \{2\}$. The peel (Definition 14.1) merges the two equal children:

$$\Big(\binom{R}{2}; \tfrac{s}{3}, \tfrac{t}{3}\Big), \quad \Big(\binom{R}{1}; \tfrac{2s}{3}, \tfrac{2t}{3}\Big), \qquad \text{word} \quad e_1(\alpha_R)^{-\frac{2s+t}{3}}\, e_2(\alpha_R)^{-\frac{s+2t}{3}}.$$

At the centre, $s = t = \sigma$, the word is $\big(e_1(\alpha_R)e_2(\alpha_R)\big)^{-\sigma}$, the word of the list $\binom{R}{1}$ at its own centre, and the gauge $\mathbf{1}_R$ is native for the masses $\sigma\mathbf{1}_R$ (Proposition 12.27); the balance is $\frac{\sigma}{3}(2+1) + \frac{2\sigma}{3}(1+2) = 3\sigma$.

The trees. The peel is one molecule, the circuit R of $\binom{R}{2}$ linking its marks (Definition 7.4), and every permutation of R carries both of its tables, so it reads every mark alike (Proposition 11.14) and is an atom at every lean (Definition 10.1). So the three Foreman trees (Theorem 14.6) have one shape: the root bunch $\{1,2\}$ of width one and the room $\{3,4,5\}$, an atom, at the exponents of the peel.

The cells. The weights are 1 and factor across B and R. The minors (Definition 7.5) are

$$\mathrm{P}_5|B = \binom{B}{1}, \qquad \mathrm{P}_5/R = \{\varnothing\}, \qquad \mathrm{P}_5|R = \binom{R}{2}, \qquad \mathrm{P}_5/B = \binom{R}{1},$$

P_5/R taking the bases inside R and P_5/B those meeting B. The cell of the bunch (Theorem 19.4) has the bases of $\mathrm{P}_5|B$ and $\varnothing + g$: it is $\binom{\{1,2,g\}}{1}$. The cell of the room has the bases of $\binom{R}{2}$ and $\{x\} + g$, $x \in R$: it is $\mathcal{A} = \binom{\{3,4,5,g\}}{2}$. The hinge values and their ratio (Definition 19.2) are

$$\gamma_B^K = \frac{K_{\mathrm{P}_5|B}}{K_{\mathrm{P}_5/R}} = \alpha_1 + \alpha_2, \qquad \gamma_B^\Psi = \frac{\Psi_{\mathrm{P}_5/R}}{\Psi_{\mathrm{P}_5|B}} = \frac{\alpha_1\alpha_2}{\alpha_1 + \alpha_2}, \qquad \varrho_B = \frac{\alpha_1\alpha_2}{(\alpha_1+\alpha_2)^2} = u(1-u)$$

on the shape $(u, 1-u)$, as for every parallel pair (Proposition 19.3).

The substitution. By Proposition 21.3(iii) P_5 is the gluing of the two cells along g: in Definition 21.1,

$$\mathrm{P}_5 = \binom{\{1,2,h\}}{1}\langle 1, 2, \mathcal{A}\rangle, \qquad \mathcal{A} = \binom{\{3,4,5,g\}}{2} \text{ at } h,$$

the marks $1, 2$ left in place. Checked on the bases: the core bases $\{1\}$ and $\{2\}$ avoid h and take $X \in \mathcal{A}/g = \binom{R}{1}$, giving the six pairs $\{1, x\}$, $\{2, x\}$; the core basis $\{h\}$ takes $X \in \mathcal{A} \setminus g = \binom{R}{2}$, giving the three pairs inside R. These are the nine bases.

The dual. $\mathcal{A} \setminus g = \binom{R}{2}$ and $\mathcal{A}/g = \binom{R}{1}$, whose bases are the complements in R of the pairs: $\mathcal{A}/g$ is the dual table of $\mathcal{A} \setminus g$, with the weights 1. So $\varrho_{\mathcal{A}} \equiv 1$ (Corollary 23.12(ii)): $\gamma_{\mathcal{A}}^{K} = e_2(\alpha_R)/e_1(\alpha_R) = \gamma_{\mathcal{A}}^{\Psi}$.

Answer. The classes are $\{1, 2\}$ and $\{3, 4, 5\}$ at the centre and at every lean, and the Foreman bunch is $\{1, 2\}$, a parallel bunch of width one. Its patterns $\varnothing, \{1\}, \{2\}$ have the probability $\frac{1}{3}$ each and the children $\binom{R}{2}, \binom{R}{1}, \binom{R}{1}$; the peel is $(\binom{R}{2}; \frac{s}{3}, \frac{t}{3})$ with $(\binom{R}{1}; \frac{2s}{3}, \frac{2t}{3})$, at the centre the word $(e_1e_2)^{-\sigma}$ on R, an atom. The three Foreman trees are the bunch $\{1, 2\}$ over that atom. And $\mathrm{P}_5 = \binom{\{1,2,h\}}{1}\langle 1, 2, \binom{\{3,4,5,g\}}{2}\rangle$, the cell of the room having its contraction $\binom{R}{1}$ dual to its deletion $\binom{R}{2}$, with the ratio 1. □

Exercise 51.6 (A Foreman bunch of width two)**.** Let T_6 be the list of rank three on $\{1, \dots, 6\}$ whose bases are the nineteen sets of three marks other than $\{1, 2, 3\}$. Show that it is prime (Theorem 23.16); find its classes at the centre and at a lean, its Foreman bunches at a basis lean and at a cobasis lean, and their widths; and draw its three Foreman trees.

Solution. Receipt: `ex05_six_marks.py`.

Ranks and widths. Every set of at most three marks other than $\{1, 2, 3\}$ is independent, $r(\{1, 2, 3\}) = 2$, and every set of at least four marks contains a basis and has rank 3. With $c(S) = r(S) + r(\mathcal{E} \setminus S) - 3$ (Definition 7.12, Theorem 7.13):

S	$c(S)$
one mark	$1 + 3 - 3 = 1$
two marks	$2 + 3 - 3 = 2$
three marks, $S \neq \{1, 2, 3\}, \{4, 5, 6\}$	$3 + 3 - 3 = 3$
$\{1, 2, 3\}$ or $\{4, 5, 6\}$	$2 + 3 - 3 = 2$
four marks	$3 + 2 - 3 = 2$

Every proper nonempty set has positive width, so the list is connected (Definition 8.1); the 50 sets with at least two marks on each side have the widths 2 (32 of them) and 3 (18), so none has width one: T_6 is prime (Theorem 23.16).

Classes. A bijection carries T_6 exactly when it maps the one triple that is not a basis, $\{1, 2, 3\}$, to itself: the 36 products of a permutation of $\{1, 2, 3\}$ and one of $\{4, 5, 6\}$, with the orbits $C = \{1, 2, 3\}$ and $D = \{4, 5, 6\}$. The cobases are the triples other than $\{4, 5, 6\}$, so a bijection exchanges T_6 exactly when it maps $\{1, 2, 3\}$ onto $\{4, 5, 6\}$, as $i \mapsto i + 3$ modulo 6 does: 36 more bijections, and the 72 together take every mark to every other. By Corollary 11.16, at the centre the one class is $\mathcal{E}$, an atom, and at every lean the classes are C and D, with the occupations $R_e(\mathbf{1}) = \frac{9}{19}$ on C and $\frac{10}{19}$ on D (Proposition 10.9(ii)).

The Foreman bunch at a lean. Both classes have three marks and lie in the one class $\mathcal{E}$ of the centre, so the key of Definition 13.6 is decided by the order $\prec$ at the lean. C and D make up the molecule, so their levels are mirrored (Proposition 13.10, with $k_j = r_j = 3$). Under the weight law,

uniform on the 19 bases (Definition 7.17), the level $N_C = |T \cap C|$ is 0 at $\{4,5,6\}$, 1 at the 9 bases with one mark of C, and 2 at the 9 with two:

$$\mathbb{P}(N_C = 0,1,2) = \tfrac{1}{19},\ \tfrac{9}{19},\ \tfrac{9}{19}; \qquad \mathbb{E}N_C = \tfrac{27}{19}.$$

The deviations $-\frac{27}{19}, -\frac{8}{19}, \frac{11}{19}$ give the cumulants

$$\kappa_{\mathbf{1}}(N_C, N_C) = \frac{9\cdot 64 + 9\cdot 121 + 729}{19^3} = \frac{126}{361},$$
$$\kappa_{\mathbf{1}}(N_C^{\times 3}) = \frac{-19683 - 9\cdot 512 + 9\cdot 1331}{19^4} = -\frac{648}{6859}.$$

The least odd order $a \geq 3$ with $\delta\,\kappa_{\mathbf{1}}(N_C^{\times a}) \neq 0$ is $a = 3$, so by Proposition 13.10(ii) $C \prec D$ exactly when $\delta\,\kappa_{\mathbf{1}}(N_C^{\times 3}) < 0$, that is at a basis lean, $\delta > 0$, and $D \prec C$ at a cobasis lean. (In Corollary 13.4(i) the coefficient of v_0^3 in the odd part of stage 0 is $\frac{2}{3!}\delta\,\kappa_{\mathbf{1}}(N_C^{\times 3}) = -\frac{216}{6859}\delta$ for C and $+\frac{216}{6859}\delta$ for D, the even parts being equal.) So

$$B(\mathrm{T}_6;\sigma,\delta) = \{1,2,3\} \quad (\delta > 0), \qquad B(\mathrm{T}_6;\sigma,\delta) = \{4,5,6\} \quad (\delta < 0),$$

each of width 2, and the exchange $i \mapsto i+3$ maps the one onto the other (Theorem 13.7(iii)).

The trees. At the centre the molecule is an atom (Definition 14.4): one leaf. At a basis lean the root bunch is C, with the patterns (Definition 12.1) and probabilities (Definition 12.25)

p	$\pi_p(\mathbf{1})$	child on $R = \{4,5,6\}$
$\varnothing$	$\frac{1}{19}$	the one basis R
$\{b\},\ b \in C$	$\frac{3}{19}$ each	$\binom{R}{2}$
$\{b,b'\} \subset C$	$\frac{3}{19}$ each	$\binom{R}{1}$

C itself not being a pattern. The peel (Definition 14.1) is the table with the one basis R at $(\frac{s}{19}, \frac{t}{19})$, $\binom{R}{2}$ at $(\frac{9s}{19}, \frac{9t}{19})$ and $\binom{R}{1}$ at $(\frac{9s}{19}, \frac{9t}{19})$; the circuit R of $\binom{R}{2}$ makes R one molecule, and every permutation of R carries the three tables, so the room is an atom (Proposition 11.14). At a cobasis lean the root bunch is D, with the patterns $\{x\}$ (child $\binom{C}{2}$), $\{x,y\}$ (child $\binom{C}{1}$), each of probability $\frac{3}{19}$, and D (child: the one basis $\varnothing$ on C) of probability $\frac{1}{19}$, $\varnothing$ not being a pattern; the room C is again an atom. The exchange $i \mapsto i+3$ maps the tree at δ onto the tree at $-\delta$ (Theorem 14.8).

Answer. T_6 is connected and prime. At the centre it is an atom. At a lean its classes are $\{1,2,3\}$ and $\{4,5,6\}$, and its Foreman bunch is $\{1,2,3\}$ at a basis lean and $\{4,5,6\}$ at a cobasis lean, both of width two. Its three Foreman trees are one atom and two trees whose root bunch, of width two, stands over a room of three marks that is an atom. □

Exercise 51.7 (What a bunch of width two shows, and what splits off)**.** For the list T_6 of Exercise 51.6 at its centre:

(i) find the levels of K along the scale of $C = \{1,2,3\}$, the Skeleton polynomial of C at the table's gauge, its discriminant and the Skeleton values there, and show that the Skeleton values along C are not rational functions of the point;

(ii) show that no set with at least two marks on each side and no complement of a single mark splits off (Theorem 28.25).

Solution. Receipt: `ex05_six_marks.py`.

(i) *The levels.* $d(C) = 0$, the basis $\{4,5,6\}$ avoiding C, and $r(C) = 2$. By the Taylor cube (Theorem 12.7) and Definition 12.16, the level 0 is the pattern $\varnothing$ with the child of the one basis R,

the level 1 the patterns $\{b\}$ with the child $\binom{R}{2}$, and the level 2 the patterns $\{b, b'\}$ with the child $\binom{R}{1}$:

$$K(x\alpha_C, \alpha_R) = \alpha_4\alpha_5\alpha_6 + x\, e_1(\alpha_C)\, e_2(\alpha_R) + x^2\, e_2(\alpha_C)\, e_1(\alpha_R),$$

each level a product of a bunch letter and a room letter.

At the table's gauge. $K(\mathbf{1}) = 19$, and the Skeleton polynomial (Definition 12.10) is

$$\mathsf{Q}^K_C(x; \mathbf{1}) = \frac{K(x\mathbf{1}_C, \mathbf{1}_R)}{K(\mathbf{1})} = \frac{1 + 9x + 9x^2}{19},$$

of degree $c(C) = 2$. The discriminant of $9x^2 + 9x + 1$ is $81 - 36 = 45$, its roots are $x = \frac{-9 \pm 3\sqrt{5}}{18}$, and the Skeleton values are their negatives,

$$\xi_{1,2} = \frac{3 \mp \sqrt{5}}{6},$$

positive and irrational.

Not rational functions. The Skeleton values at α are the negatives of the roots of $K(x\alpha_C, \alpha_R)$ in x, so

$$(\xi_1 - \xi_2)^2\, e_2(\alpha_C)^2\, e_1(\alpha_R)^2 = \Delta(\alpha) := e_1(\alpha_C)^2 e_2(\alpha_R)^2 - 4\, e_2(\alpha_C)\, e_1(\alpha_R)\, \alpha_4\alpha_5\alpha_6.$$

If ξ_1, ξ_2 were rational functions of α, Δ would be the square of a rational function, hence, the polynomial ring being a unique factorization domain, the square of a polynomial, and so would its restriction to every line. On $\alpha = (1, 1, 1, 1, 1, \lambda)$, $e_1(\alpha_C) = e_2(\alpha_C) = 3$, $e_1(\alpha_R) = 2 + \lambda$, $e_2(\alpha_R) = 1 + 2\lambda$ and $\alpha_4\alpha_5\alpha_6 = \lambda$:

$$\Delta = 9(1 + 2\lambda)^2 - 12\lambda(2 + \lambda) = 3\,(8\lambda^2 + 4\lambda + 3),$$

and $8\lambda^2 + 4\lambda + 3$ has the discriminant $16 - 96 = -80$: two simple roots, so Δ is not a square on this line. The value 45 at the gauge shows only that the Skeleton values are irrational numbers there; the line shows that they are not rational functions of the point.

(ii) *Sets with two marks on each side.* T_6 is prime (Exercise 51.6), and at its centre, masses $\sigma\mathbf{1}$, every proper wall is positive (Proposition 8.21(ii)); so by Corollary 28.26(ii) no set with at least two marks on each side splits off. Each such set has width two or three and enters every period of the list through a law carried by no point (Corollary 28.26(i)).

Complements of single marks. $\mathcal{E} \setminus \{e\}$ has the width $c(\{e\}) = 1$ (Theorem 7.13); with both letters active, Corollary 28.26(iv) says it splits off exactly when the deletion and the contraction at e have one even letter, $\mathbf{E}_{\mathrm{T}_6\setminus e} = \mathbf{E}_{\mathrm{T}_6/e}$ (Definition 7.3). For $e \in C$ the deletion has as its bases all ten triples of $\mathcal{E} \setminus \{e\}$ and the contraction the nine pairs $\{x, y\}$ of $\mathcal{E} \setminus \{e\}$ with $\{e, x, y\} \neq \{1, 2, 3\}$; for $e \in D$ the deletion has nine bases and the contraction ten. At the table's gauge $\mathbf{E} = K\Psi$ is the square of the number of bases, so

$$\mathbf{E}_{\mathrm{T}_6\setminus e}(\mathbf{1}) = 100, \quad \mathbf{E}_{\mathrm{T}_6/e}(\mathbf{1}) = 81 \quad (e \in C); \qquad \mathbf{E}_{\mathrm{T}_6\setminus e}(\mathbf{1}) = 81, \quad \mathbf{E}_{\mathrm{T}_6/e}(\mathbf{1}) = 100 \quad (e \in D):$$

the two even letters differ, and no complement of a mark splits off at the centre.

Answer. Along C the levels are $\alpha_4\alpha_5\alpha_6$, $e_1(\alpha_C)e_2(\alpha_R)$ and $e_2(\alpha_C)e_1(\alpha_R)$; at the table's gauge $K(x\mathbf{1}_C, \mathbf{1}_R) = 1 + 9x + 9x^2$, with the discriminant 45 and the Skeleton values $\frac{3\mp\sqrt{5}}{6}$; on the line $(1, 1, 1, 1, 1, \lambda)$ the discriminant is $3(8\lambda^2 + 4\lambda + 3)$, not a square, so the Skeleton values are not rational functions of the point. At the centre no set with at least two marks on each side and no complement of a mark splits off: T_6 is its own and only factor. (At a full lean each complement of a mark does split off, Corollary 28.26(iii).) □

51.4 Skeleton values at width two

Exercise 51.8 (Skeleton values of $\binom{[4]}{2}$ along a pair)**.** For the list $\binom{[4]}{2}$ and its bunch $B = \{1, 2\}$, find the width of B, the levels of K along the scale of B, the Skeleton polynomial and the Skeleton values at the table's gauge, and show that the Skeleton values are not rational functions of the point. Why does the value of the discriminant at the table's gauge not settle this?

Solution. Receipt: `ex06_skeleton_u24.py`.

The width. The basis $\{3, 4\}$ avoids B and the basis $\{1, 2\}$ is B, so the window of B is $\{0, 1, 2\}$: $d(B) = 0$, $r(B) = 2$ and $c(B) = 2$ (Theorem 7.13).

The levels. The patterns are $\varnothing$ (child: the one basis $\{3, 4\}$), $\{1\}$ and $\{2\}$ (child $\binom{\{3,4\}}{1}$, with $K = \alpha_3 + \alpha_4$) and $\{1, 2\}$ (child: the one basis $\varnothing$). By Theorem 12.7 and Definition 12.16,

$$K(\rho\alpha_1, \rho\alpha_2, \alpha_3, \alpha_4) = \alpha_3\alpha_4 + \rho\,(\alpha_1 + \alpha_2)(\alpha_3 + \alpha_4) + \rho^2\alpha_1\alpha_2.$$

The Skeleton polynomial is $\mathsf{Q}_B^K(x; \alpha) = K(x\alpha_B, \alpha_R)/K(\alpha)$ (Definition 12.10), of degree 2, whose roots $-\xi_1, -\xi_2$ have

$$\xi_1 + \xi_2 = \frac{(\alpha_1 + \alpha_2)(\alpha_3 + \alpha_4)}{\alpha_1\alpha_2}, \qquad \xi_1\xi_2 = \frac{\alpha_3\alpha_4}{\alpha_1\alpha_2}.$$

The list is identically self-dual and $d^*(B) = 0$, so Ψ has the same levels along B and the same Skeleton values.

At the table's gauge. $K(x\mathbf{1}_B, \mathbf{1}_R) = 1 + 4x + x^2$ and $K(\mathbf{1}) = 6$; the discriminant is $16 - 4 = 12$, and the Skeleton values are $\xi = 2 \pm \sqrt{3}$, irrational.

What the value at the gauge decides. $(\xi_1 - \xi_2)^2(\alpha_1\alpha_2)^2 = \Delta(\alpha) := (\alpha_1 + \alpha_2)^2(\alpha_3 + \alpha_4)^2 - 4\alpha_1\alpha_2\alpha_3\alpha_4$, and $\Delta(\mathbf{1}) = 12$ is not the square of a rational number. That shows that the Skeleton values are irrational numbers at the gauge, and no more: if Δ were $3q(\alpha)^2$ for a polynomial q with rational coefficients, $\xi_{1,2} = \frac{(\alpha_1+\alpha_2)(\alpha_3+\alpha_4) \mp \sqrt{3}\,q}{2\alpha_1\alpha_2}$ would be rational functions of the point, with the value 12 at the gauge.

Not rational functions. If ξ_1, ξ_2 are rational functions of α, Δ is the square of a rational function, so of a polynomial (unique factorization in the polynomial ring), and so is its restriction to every line: Δ would be a constant times the square of a polynomial with rational coefficients. On $\alpha = (1, 1, 1, \lambda)$,

$$\Delta = 4(1 + \lambda)^2 - 4\lambda = 4(\lambda^2 + \lambda + 1),$$

whose roots $\frac{-1 \pm \sqrt{-3}}{2}$ are simple. So Δ is not a constant times a square, and the Skeleton values along B are not rational functions of the point.

Answer. B has width two, with the levels $\alpha_3\alpha_4$, $(\alpha_1+\alpha_2)(\alpha_3+\alpha_4)$ and $\alpha_1\alpha_2$; at the table's gauge the Skeleton polynomial is $(1+4x+x^2)/6$ and the Skeleton values are $2 \pm \sqrt{3}$. The discriminant is $4(\lambda^2 + \lambda + 1)$ on the line $(1, 1, 1, \lambda)$, not a constant times a square, so the Skeleton values are not rational functions of the point. The value 12 at the gauge only excludes a rational square, not a constant times a square. At width one, by contrast, the one Skeleton value is the quotient of two hinge values (Corollary 19.5). □

51.5 The record of a peel

Exercise 51.9 (Peeling with and without the record)**.** Let

$$F = \left(\left(\binom{[5]}{2}; 1, 0\right), \left(\binom{[5]}{3}; -1, 0\right), \left(\binom{[5]}{4}; 4, 0\right)\right)$$

on $\mathcal{E} = \{1, \dots, 5\}$, with the masses $3\mathbf{1}$. Show that it is on its balance wall with every proper wall positive and that the table's gauge is native; peel it at $\{1\}$ with the native split of the table's gauge, write its record and its peel, and compare the letters they carry. What changes when every exponent is nonnegative?

Solution. Receipt: `ex07_record.py`.

Walls. The exponents are $s_j = 1, -1, 4$ and $t_j = 0$; the ranks are $2, 3, 4$. The balance is $\sum_j s_j r_j = 2 - 3 + 16 = 15 = m_{\mathcal{E}}$. In $\binom{\mathcal{E}}{r}$ a set S meets every basis in at least $d(S) = \max\big(0, |S| - (5 - r)\big)$ marks (Theorem 7.13), so the walls $\kappa_S = m_S - \sum_j s_j d_j(S)$ (Definition 8.1) depend on $|S|$ alone:

$\lvert S\rvert$	1	2	3	4	5
(d_1, d_2, d_3)	$(0,0,0)$	$(0,0,1)$	$(0,1,2)$	$(1,2,3)$	$(2,3,4)$
κ_S	3	2	2	1	0

every proper wall is positive and $\kappa_{\mathcal{E}} = 0$.

The native gauge. On the balance wall the target is $\mathbf{m}$ (Definition 8.17). At the table's gauge the occupation in $\binom{\mathcal{E}}{r}$ is $\frac{r}{5}$ at every mark, so the usage is $1 \cdot \frac{2}{5} - 1 \cdot \frac{3}{5} + 4 \cdot \frac{4}{5} = 3 = m_e$: the gauge $\mathbf{1}$ is native. An exponent is negative, so F has no realization (Definition 9.1) and no Foreman tree (Definition 14.4); its native split (Definition 12.25), its record and its peel are defined at the native gauge $\mathbf{1}$.

The record. The patterns of $\{1\}$ in $\binom{\mathcal{E}}{r}$ are $\varnothing$, with the child $\binom{R}{r}$ on $R = \{2, 3, 4, 5\}$ and the probability $\binom{4}{r}/\binom{5}{r} = \frac{5-r}{5}$, and $\{1\}$, with the child $\binom{R}{r-1}$ and the probability $\frac{r}{5}$ (Definitions 12.1 and 12.25). The record (Definition 14.2) is the six indexed children, each with the exponents $\pi_{j,p}(\mathbf{1})(s_j, 0)$:

table j	p	child	exponents
1	$\varnothing$	$\binom{R}{2}$	$(\frac{3}{5}, 0)$
1	$\{1\}$	$\binom{R}{1}$	$(\frac{2}{5}, 0)$
2	$\varnothing$	$\binom{R}{3}$	$(-\frac{2}{5}, 0)$
2	$\{1\}$	$\binom{R}{2}$	$(-\frac{3}{5}, 0)$
3	$\varnothing$	$\binom{R}{4}$	$(\frac{4}{5}, 0)$
3	$\{1\}$	$\binom{R}{3}$	$(\frac{16}{5}, 0)$

On R the children lie on their balance wall at the masses $3\mathbf{1}_R$, $\frac{3}{5} \cdot 2 + \frac{2}{5} \cdot 1 - \frac{2}{5} \cdot 3 - \frac{3}{5} \cdot 2 + \frac{4}{5} \cdot 4 + \frac{16}{5} \cdot 3 = 12$, and their usage at $\mathbf{1}_R$ is 3 at every mark (Theorem 12.26). The record determines F (Proposition 14.3): table j is the gluing of its two children, and their exponents add to 1, -1 and 4.

The peel. Definition 14.1 merges the children with the same bases, adding their exponents:

$$\Big(\binom{R}{1}; \tfrac{2}{5}, 0\Big), \qquad \Big(\binom{R}{2}; \tfrac{3}{5} - \tfrac{3}{5}, 0\Big) = \Big(\binom{R}{2}; 0, 0\Big), \qquad \Big(\binom{R}{3}; \tfrac{14}{5}, 0\Big), \qquad \Big(\binom{R}{4}; \tfrac{4}{5}, 0\Big).$$

The table $\binom{R}{2}$ has both exponents zero: it is not active, and the peel carries no letter $e_2(\alpha_R)$ (Definition 8.1). The record carries it twice, in the child $(1, \varnothing)$ at the exponent $\frac{3}{5}$ and in the child $(2, \{1\})$ at $-\frac{3}{5}$. The two words agree,

$$e_1(\alpha_R)^{-2/5}\, e_3(\alpha_R)^{-14/5}\, e_4(\alpha_R)^{-4/5},$$

since $e_2^{-3/5} e_2^{3/5} = 1$; what the peel loses is which pattern of which table each share came from, which the record keeps (the paragraph after Proposition 14.3), and with it the letter $e_2(\alpha_R)$ that the tables 1 and 2 hand to the room.

Nonnegative exponents. When every $s_j, t_j \geq 0$, every child carries $\pi_{j,p}(\mathbf{1})\,(s_j, t_j)$ with $\pi_{j,p}(\mathbf{1}) > 0$ (Proposition 12.27); a merged exponent is a sum of nonnegative terms, zero only when each term is, so merging loses no letter, and a full lean is handed down full, table by table. This is the scope of the realizations, where the Foreman tree is read.

Answer. F is on its balance wall with the walls $3, 2, 2, 1$ at the sets of $1, 2, 3, 4$ marks, and the table's gauge is native. Its record at $\{1\}$ is the six children of the table displayed; its peel is $\binom{R}{1}$, $\binom{R}{3}$, $\binom{R}{4}$ at $\frac{2}{5}$, $\frac{14}{5}$, $\frac{4}{5}$, the child $\binom{R}{2}$ cancelling between the tables 1 and 2: merging loses the letter e_2 on the room, which the record keeps. With nonnegative exponents no letter is lost. $\square$

Chapter 52

Exercises on evaluation and construction

The exercises of this chapter work the statements of Parts IV and V on particular lists. A set of width two whose stations of room sides are single room sides cannot be opened with one share per station, the room's seam function being infinite at every share, and it is opened with the transverse pins instead. The width of the marks left in place by a substitution is read off the core, bounded by the number of the other cells, and every width occurs. The uniform list of rank two on five marks is fused by the procedure of Foreman fusion: its fusion, its one major, its cousins and the symmetry the fusion adds. Every number displayed is exact; the receipts that recompute them are the scripts named in each solution.

52.1 One share per station

Exercise 52.1 (One share per station at a set of width two)**.** Let Q_5 be the list on $\{1,\dots,5\}$ whose bases are the eight sets of three marks other than $\{1,2,5\}$ and $\{3,4,5\}$, at its centre $(\mathbf{1};1,1)$, and let $S=\{1,2,3\}$, with the room $R=\{4,5\}$.

(i) Find the width of S, its patterns and room sides at every excess, its stations, its seam letters and the room station letters (Definition 28.1), and check the room-station factorization.

(ii) Read the period with one share per station (Theorem 28.10(iii)): write the pins of the seam and the room word, and show that the seam function of the room is $+\infty$ at every share.

(iii) Read it with the transverse pins of Theorem 28.12: find the lattice, the pins, the reduced periods and the share side, and check that the native split at the stations lies on the pins, with the masses of S inside the Newton sum of the seam word there.

Solution. Receipt: `ex08_transverse.py`.

(i) *The list.* Its circuits (Definition 7.4) are the two triples $\{1,2,5\}$ and $\{3,4,5\}$ that are not bases and the set $\{1,2,3,4\}$, all of whose triples are bases; the rank is 3 and the corank 2. In S every basis has one to three marks: $r(S)=3$, S being a basis, $r(R)=2$, and by Definition 7.12 and Theorem 7.13

$$d(S)=r-r(R)=1,\qquad d^*(S)=|S|-r(S)=0,\qquad c(S)=r(S)-d(S)=2,$$
$$d(R)=d^*(R)=0,\qquad c(R)=2.$$

Patterns and room sides. An excess i is the level $d(S)+i=1+i$ (Definition 28.1); its patterns have $1+i$ marks and its room sides $2-i$. With the children (Definition 12.1) and the room children:

i	patterns : children on R	room sides : room children on S
0	$\{1\},\{2\}$: $\{45\}$	$\{4,5\}$: $\{1\},\{2\}$
1	$\{1,2\}$: $\{4\}$; $\{1,3\},\{2,3\}$: $\{4\},\{5\}$	$\{4\}$: $\{12\},\{13\},\{23\}$; $\{5\}$: $\{13\},\{23\}$
2	$\{1,2,3\}$: $\{\varnothing\}$	$\varnothing$: $\{123\}$

The two room sides of the excess 1 have room children with three and with two bases, not multiples of one another; so every room side is its own station: $D_0=\{\{4,5\}\}$, $D_1=\{\{4\}\}$, $D_1'=\{\{5\}\}$ and $D_2=\{\varnothing\}$. The stations of patterns are $\{\{1\},\{2\}\}$, $\{\{1,2\}\}$, $\{\{1,3\},\{2,3\}\}$ and $\{\{1,2,3\}\}$. For a list every multiplier and pair constant is 1.

Seam letters and room station letters. The seam letters are the letters of the room children, on S, and the room station letters are $\mathsf{y}_D=\alpha_R^X$ and $\mathsf{y}_D^*=\alpha_R^{R\setminus X}$ for the one room side X of D (Definition 28.1(iii)):

D	$V_D=K_{(D)}$	$V_D^*=\Psi_{(D)}$	y_D	y_D^*
D_0	$\alpha_1+\alpha_2$	$\alpha_3(\alpha_1+\alpha_2)$	$\alpha_4\alpha_5$	1
D_1	$e_2(\alpha_S)$	$e_1(\alpha_S)$	α_4	α_5
D_1'	$\alpha_3(\alpha_1+\alpha_2)$	$\alpha_1+\alpha_2$	α_5	α_4
D_2	$\alpha_1\alpha_2\alpha_3$	1	1	$\alpha_4\alpha_5$

The room-station factorization (Proposition 28.2(iii)):

$$K=(\alpha_1+\alpha_2)\,\alpha_4\alpha_5+e_2(\alpha_S)\,\alpha_4+\alpha_3(\alpha_1+\alpha_2)\,\alpha_5+\alpha_1\alpha_2\alpha_3,$$
$$\Psi=\alpha_3(\alpha_1+\alpha_2)+e_1(\alpha_S)\,\alpha_5+(\alpha_1+\alpha_2)\,\alpha_4+\alpha_4\alpha_5,$$

the eight bases and the eight cobases, each once.

The walls. At $(\mathbf{1};1,1)$, $\kappa_S=m_S-d(S)-d^*(S)=2$, $\kappa_R=m_R-d(R)-d^*(R)=2$, and the top wall of S is $(s+t)\,c(S)-\kappa_S=2=\kappa_R$ (Definition 28.4): the glue is on its balance wall.

(ii) *The pins of the seam.* One share per station and letter: a_D for K and b_D for Ψ, $D\in\{D_0,D_1,D_1',D_2\}$. By Lemma 28.7 the pins are the two letter totals and the scale pin, whose coefficients are the excesses $i(D)$ for K and $c(S)-i(D)$ for Ψ:

$$a_{D_0}+a_{D_1}+a_{D_1'}+a_{D_2}=1,\qquad b_{D_0}+b_{D_1}+b_{D_1'}+b_{D_2}=1,$$
$$a_{D_1}+a_{D_1'}+2a_{D_2}+2b_{D_0}+b_{D_1}+b_{D_1'}=\kappa_S=2.$$

The room word. The room is the partner with the room letters $L_D=\mathsf{y}_D$ and $L_D^*=\mathsf{y}_D^*$ (the paragraph after Definition 28.4), so its word is the monomial

$$W_R(\mathbf{a},\mathbf{b})=\prod_D \mathsf{y}_D^{-a_D}\,{\mathsf{y}_D^*}^{-b_D}=\alpha_4^{-p_4}\alpha_5^{-p_5},$$
$$p_4=a_{D_0}+a_{D_1}+b_{D_1'}+b_{D_2},\qquad p_5=a_{D_0}+a_{D_1'}+b_{D_1}+b_{D_2},$$

and $p_4+p_5=2\big(|\mathbf{a}|+|\mathbf{b}|\big)-\big(a_{D_1}+a_{D_1'}+2a_{D_2}+2b_{D_0}+b_{D_1}+b_{D_1'}\big)=4-2=2=m_4+m_5$ on the pins.

Its seam function. The seam function of the room is the period of its word at $\mathbf{m}_R=(1,1)$ (Lemma 28.7, read on the partner, whose pins on the balance wall are those of the seam; Theorem 28.10(iii)). On the section $\alpha_5=1$ (Definition 25.1) it is

$$\int_0^\infty \alpha_4^{1-p_4}\,\frac{d\alpha_4}{\alpha_4}=+\infty$$

at every real value of p_4: the integrand is a power, which is not integrable at 0 when its exponent is at most -1 and not at ∞ when it is at least -1. Every room letter is a monomial because every room side is its own station, so the Newton sum of the room word is one point, of dimension $0 < |R| - 1$, and Theorem 25.2 excludes convergence at every share. No point of the pins has both seam functions finite: the display of Theorem 28.10(iii), a fibre integral of the dimension $2 \cdot 4 - 2 - 1 = 5$, does not hold here. Its parts (i) and (ii) hold in every case.

(iii) *The Newton sums.* At shares with positive real parts the seam word of S,

$$W_S(\mathbf{a},\mathbf{b}) = \prod_D V_D^{-a_D} V_D^{*-b_D}$$
$$= (\alpha_1+\alpha_2)^{-a_{D_0}-b_{D_1'}} \big(\alpha_3(\alpha_1+\alpha_2)\big)^{-b_{D_0}-a_{D_1'}} e_2(\alpha_S)^{-a_{D_1}} e_1(\alpha_S)^{-b_{D_1}} (\alpha_1\alpha_2\alpha_3)^{-a_{D_2}},$$

has a Newton sum that contains b_{D_1} times the triangle $\operatorname{conv}\{\mathbf{1}_{\{1\}}, \mathbf{1}_{\{2\}}, \mathbf{1}_{\{3\}}\}$ of $e_1(\alpha_S)$ (Definition 25.1): its space of directions is $\vec{\mathcal{N}}_S = \{x \in \mathbb{R}^S : \ x_1 + x_2 + x_3 = 0\}$. The room word is a monomial, $\vec{\mathcal{N}}_R = 0$.

The lattice and the pins. In Theorem 28.12,

$$M = \vec{\mathcal{N}}_S^{\perp} \oplus \vec{\mathcal{N}}_R^{\perp} = \mathbb{R}\mathbf{1}_S \oplus \mathbb{R}^{\{4,5\}},$$

of dimension 3, containing $\mathbf{1}$; $M \cap \mathbb{Z}^5 = \{(a,a,a,b,c)\}$ has the basis $\mathbf{1}, \mathbf{e}_4, \mathbf{e}_5$, since $\mathbf{1}_S = \mathbf{1} - \mathbf{e}_4 - \mathbf{e}_5$. So $q = 2$, $\mathbf{v}_1 = \mathbf{e}_4$ and $\mathbf{v}_2 = \mathbf{e}_5$. The fixed monomials of the seam letters live on S, and those of the room letters are the room letters themselves, so $\langle \mathbf{n}(\mathbf{a},\mathbf{b}), \mathbf{e}_4 \rangle = p_4$ and $\langle \mathbf{n}(\mathbf{a},\mathbf{b}), \mathbf{e}_5 \rangle = p_5$. The pins are the letter totals and

$$a_{D_0} + a_{D_1} + b_{D_1'} + b_{D_2} = m_4 = 1, \qquad a_{D_0} + a_{D_1'} + b_{D_1} + b_{D_2} = m_5 = 1 :$$

four pins on eight shares, a fibre of the dimension 4. With the totals they imply the scale pin, by the identity for $p_4 + p_5$ in (ii).

The reduced periods. $\vec{\mathcal{N}}_S^{\perp} = \mathbb{R}\mathbf{1}_S$, so the reduced period of the seam word is its integral over $\mathbb{R}^S/\mathbb{R}\mathbf{1}_S$, that is over a section: the period $P_{W_S(\mathbf{a},\mathbf{b})}(\mathbf{1}_S)$ (Definition 25.1). $\vec{\mathcal{N}}_R^{\perp} = \mathbb{R}^R$, so the quotient is a point, and the reduced period of the room word is the value of $\alpha_4^{m_4-p_4}\alpha_5^{m_5-p_5}$, which is 1 on the pins, the room letters having the coefficient 1.

The share side. The share kernels are $\Gamma_{\begin{smallmatrix}4\\1\end{smallmatrix}}\begin{bmatrix}\mathbf{a}\\1\end{bmatrix} = \prod_D \Gamma(a_D)$ and $\Gamma_{\begin{smallmatrix}4\\1\end{smallmatrix}}\begin{bmatrix}\mathbf{b}\\1\end{bmatrix} = \prod_D \Gamma(b_D)$, $\Gamma(1) = 1$ (Definition 1.2). So, on every contour of the pins with positive real parts at which P_{W_S} converges,

$$P_{\mathrm{Q}_5}(\mathbf{1}; 1, 1) = \int_{\text{pins}} \prod_D \Gamma(a_D)\,\Gamma(b_D)\; P_{W_S(\mathbf{a},\mathbf{b})}(1,1,1),$$

the pins being $|\mathbf{a}| = |\mathbf{b}| = 1$ and $p_4 = p_5 = 1$.

The native split. At the table's gauge the basis law is uniform on the eight bases and the cobasis law is the same law (Theorem 7.16). $T \cap R$ is $\{4,5\}$ at $145, 245$, $\{4\}$ at $124, 134, 234$, $\{5\}$ at $135, 235$ and $\varnothing$ at 123, so Lemma 28.9 gives

$$a_D^{\star} = b_D^{\star} = \tfrac{1}{4},\ \tfrac{3}{8},\ \tfrac{1}{4},\ \tfrac{1}{8} \qquad (D = D_0, D_1, D_1', D_2),$$

with the totals 1 and 1, $p_4 = \frac{1}{4} + \frac{3}{8} + \frac{1}{4} + \frac{1}{8} = 1$ and $p_5 = \frac{1}{4} + \frac{1}{4} + \frac{3}{8} + \frac{1}{8} = 1$: the native split lies on the transverse pins, with positive coordinates. There $\mathbf{1}_S$ lies in the relative interior of the Newton sum of the seam word (Lemma 28.9); the receipt checks it exactly, the support function

of the Newton sum exceeding $\langle u, \mathbf{1}_S\rangle$ by at least $\frac{9}{8}$ at every edge normal u of its summands. So $P_{W_S(\mathbf{a}^\star,\mathbf{b}^\star)}(\mathbf{1}_S)$ converges (Theorem 25.2), and the contour through the native split carries the display.

Answer. S has width two; its four stations of room sides are the single room sides $\{4,5\}$, $\{4\}$, $\{5\}$, $\varnothing$, the room letters are monomials, and the seam function of the room is $+\infty$ at every share, so the period does not open with one share per station. With the transverse pins $p_4 = p_5 = 1$ in place of the scale pin it opens as the fibre integral of dimension four displayed, the seam word of S against the share kernels, the room contributing 1. □

52.2 The width of the marks left in place

Exercise 52.2 (The width of a bunch of a substitution)**.** Let $\mathrm{M}_8 = \binom{\{b_1,b_2,h_1,h_2\}}{2}\langle b_1, b_2, \mathcal{A}_1, \mathcal{A}_2\rangle$, the marks b_1, b_2 left in place and the cells $\mathcal{A}_i = \binom{\{x_i,y_i,z_i,g_i\}}{2}$ at h_i, with $R_i = \{x_i, y_i, z_i\}$ (Definition 21.1).

(i) Find the rank and the bases of M_8, and the widths of $\{b_1\}$, $\{b_2\}$ and $B = \{b_1, b_2\}$, from the bases and from the core; compare with the bound of Corollary 21.11.

(ii) Write K along the scale of B.

(iii) For $c = 1, 2, 3$ let $B = \{b_1, \dots, b_c\}$ be left in place in the core $\binom{B\sqcup\{h_1,\dots,h_c\}}{c}$, with the cells $\binom{\{x_i,y_i,z_i,g_i\}}{2}$ at the h_i. Find the width of B.

Solution. Receipt: `ex09_width_subst.py`.

(i) *Rank and bases.* The core has the rank 2, each cell $\mathcal{A}_i$ the rank 2, and a mark left in place the cell $\binom{\{b,g\}}{1}$ of rank 1; so M_8 is a table of rank $2 + (2-1) + (2-1) = 4$ on eight marks (Proposition 21.3(i)). Its bases (Definition 21.1) are read off the six bases T of the core: $b \in T \cap B$ gives the mark b, and at h_i the cell gives a basis of $\mathcal{A}_i \setminus g_i = \binom{R_i}{2}$ when $h_i \in T$ and one of $\mathcal{A}_i/g_i = \binom{R_i}{1}$ when $h_i \notin T$, three choices each: $6 \cdot 9 = 54$ bases.

Widths. From the bases, the numbers of marks of $\{b_1\}$, $\{b_2\}$ and B in a basis fill the windows $\{0,1\}$, $\{0,1\}$ and $\{0,1,2\}$ (Theorem 7.13): the widths are 1, 1 and 2. In the core $\binom{\{b_1,b_2,h_1,h_2\}}{2}$ a pair meets one mark in 0 or 1 marks and a pair of marks in 0, 1 or 2: the same widths. That is Corollary 21.11: a set of marks left in place has the width it has in the core. In Theorem 21.10 the cell $\binom{\{b,g\}}{1}$ of a mark b of $S \subseteq \{b_1, b_2\}$ has $d(\{b\}) = d^*(\{b\}) = 0$ and $d(\{b,g\}) = d^*(\{b,g\}) = 1$, the cells $\mathcal{A}_i$ meet S in $\varnothing$ with $d(\{g_i\}) = d^*(\{g_i\}) = 0$, so $D(S) = D^*(S) = S$ and $d(S) = d_{\mathcal{H}}(S) = 0$, $d^*(S) = d^*_{\mathcal{H}}(S) = 0$.

The bound. With $L = \{b_1, b_2\}$ and the two cells, $c(S) \le |L \setminus S| + 2$: $1 \le 3$ for $\{b_1\}$ and $\{b_2\}$, and $2 \le 2$ for B, where it is attained. For the list $\mathrm{P}_5 = \binom{\{1,2,h\}}{1}\langle 1, 2, \binom{\{3,4,5,g\}}{2}\rangle$ of Exercise 51.5 the bound at its Foreman bunch $\{1,2\}$ is $0 + 1 = 1$, attained as well.

(ii) *The letter along B.* The cells have $K_{\mathcal{A}_i/g_i} = e_1(\alpha_{R_i})$ and the hinge values $\gamma_i := \gamma^K_{\mathcal{A}_i} = e_2(\alpha_{R_i})/e_1(\alpha_{R_i})$ (Definition 21.1); their contractions $\binom{R_i}{1}$ are the duals of their deletions $\binom{R_i}{2}$, so also $\gamma^\Psi_{\mathcal{A}_i} = \gamma_i$ (Corollary 23.12(ii)). The core letter is e_2 on four marks, so by Theorem 21.4

$$K(\tau\alpha_B, \alpha_R) = e_1(\alpha_{R_1})\, e_1(\alpha_{R_2})\Big(\gamma_1\gamma_2 + \tau\,(\alpha_{b_1} + \alpha_{b_2})(\gamma_1 + \gamma_2) + \tau^2\alpha_{b_1}\alpha_{b_2}\Big)\,:$$

three levels, the width two, and the room sees B only through the two hinge values of the cells and the marks of B.

(iii) In the core $\binom{B\sqcup\{h_1,\dots,h_c\}}{c}$, $|B| = c$, the sets of c marks meet B in every number of marks from 0 to c, so B has the width c (Theorem 7.13); no h_i is a loop or a coloop, and by Corollary 21.11

the width stays c after the cells are substituted. From the bases:

c	marks	rank	bases	window of B	$c(B)$
1	4	2	6	$\{0,1\}$	1
2	8	4	54	$\{0,1,2\}$	2
3	12	6	540	$\{0,1,2,3\}$	3

At $c=1$ the substitution $\binom{\{b_1,h_1\}}{1}\langle b_1,\mathcal{A}_1\rangle$ is the list $\binom{\{b_1,x_1,y_1,z_1\}}{2}$ itself, and at $c=2$ it is M_8. In each case the bound $|L\setminus B|+c=c$ is attained.

Answer. M_8 is a list of rank four on eight marks with 54 bases; $\{b_1\}$ and $\{b_2\}$ have width one and $B=\{b_1,b_2\}$ width two, as in the core, against the bounds 3, 3 and 2. Along B, $K=e_1(\alpha_{R_1})e_1(\alpha_{R_2})(\gamma_1\gamma_2+\tau(\alpha_{b_1}+\alpha_{b_2})(\gamma_1+\gamma_2)+\tau^2\alpha_{b_1}\alpha_{b_2})$. In $\binom{B\sqcup\{h_1,\dots,h_c\}}{c}$ with cells at the h_i the bunch B has the width c for $c=1,2,3$: a bunch that is all the marks left in place has at most as much width as there are cells, and every width occurs. □

52.3 Fusing a uniform list

Exercise 52.3 (Fusing $\binom{[5]}{2}$)**.** Run the procedure of Section 30.7 on the list $\binom{[5]}{2}$, read at its centre: decide each step, find its fusion width, its tell, its Foreman fusion with its letter, its lifts and its majors, and its cousins; read the period of the fusion through two of its cousins; and find the index of the bijections carrying $\binom{[5]}{2}$, times the permutations of the fusion bunch, among those carrying its fusion.

Solution. Receipt: `ex10_fusion_u25.py`.

(1) Peel. Every permutation of [5] maps pairs to pairs and carries the list, so at the centre, and at every lean, all marks lie in one class (Corollary 11.16): the realization is an atom (Definition 10.1) and nothing is peeled (Definition 14.4).

(2) Go down. The complement of a basis is a triple, not a basis: the list is not identically self-dual (Corollary 23.12(iii)).

(3) Go up. The rank is $r=2$ and the corank $r^*=3$, so the fusion width is $c=r^*-r=1$ (Definition 30.4). The circuits (Definition 7.4) are the ten triples, every pair being independent; the cocircuits, the least sets meeting every pair, are the five sets of four marks. Each cocircuit is the union of the four triples inside it, so the tell (Theorem 30.6(b)) holds. In its form (c): for a mark e and a split of the other four marks into two halves, one half has at least two marks, the rank 2, which e does not raise. The form (a), $r^*(Y)-r^*(X)\geq r(Y)-r(X)$ for all $X\subseteq Y$, the receipt checks on the rank functions. At $c=1$ the weights play no part: $\binom{[5]}{2}$ is fusable.

The fusion. With the fusion bunch $G=\{g\}$, Theorem 30.5(v) gives the bases $T+g$, T a pair of [5], and $[5]\setminus T$, the triples of [5]: ten and ten, all twenty triples of $[5]\sqcup\{g\}$. So

$$\mathcal{B}^\sharp=\binom{[5]\sqcup\{g\}}{3},\qquad K^\sharp=\Psi+\alpha_g K=e_3(\alpha_{[5]})+\alpha_g\,e_2(\alpha_{[5]})=e_3(\alpha_{[5]\sqcup\{g\}})=\Psi^\sharp,$$

identically self-dual, the complement of a triple of six marks being a triple. The lifts (Definition 30.4(ii)) are $\mathcal{L}_0=\binom{[5]}{2}$ and $\mathcal{L}_1=\binom{[5]}{3}$, its dual, with the lift letters $L_0=\Psi=e_3$ and $L_1=K=e_2$; at $c=1$ there are no middle weights and no lift ratios, and $K^\sharp=L_0+\alpha_g L_1$ is Theorem 30.5(ii).

The majors. A table on $[5]\sqcup\{g\}$ whose contraction of g is $\binom{[5]}{2}$ has as its bases through g the sets $T+g$, $T\in\binom{[5]}{2}$, and one whose deletion of g is $\binom{[5]}{3}$ has as its bases avoiding g the triples of

[5] (Definition 7.3). A major (Definition 30.4(i)) has both, so its bases are the twenty triples, and $\mathcal{B}^\sharp$ is the only major, as Theorem 30.5(v) says.

One Beta corner. On the balance wall of the fusion, $m_{[5]}+m_g = 2\sigma r^* = 6\sigma$, with every proper wall positive, Corollary 30.13 gives

$$P_{\binom{[6]}{3}}\big(\mathbf{m}|_{[5]}, m_g; s, t\big) = \Gamma^{\,2}_{\,1}\begin{bmatrix} m_g, & 2\sigma - m_g \\ & 2\sigma \end{bmatrix} P_{\binom{[5]}{2}}\big(\mathbf{m}|_{[5]}; m_g, 2\sigma - m_g\big),$$

[6] written for $[5]\sqcup\{g\}$. It can be read off the letter: the fused table is the family $\big(\binom{[6]}{3}; 2\sigma, 0\big)$ (the paragraph after Definition 30.11), and on the section $|\alpha_{[5]}| = 1$ the scale of g integrates out, with $\alpha_g = (e_3/e_2)v$,

$$\begin{aligned}\int_0^\infty \alpha_g^{\,m_g-1}\big(e_3 + \alpha_g\, e_2\big)^{-2\sigma} d\alpha_g &= e_3^{\,m_g-2\sigma} e_2^{\,-m_g} \int_0^\infty v^{m_g-1}(1+v)^{-2\sigma} dv \\ &= \Gamma^{\,2}_{\,1}\begin{bmatrix} m_g, & 2\sigma - m_g \\ & 2\sigma \end{bmatrix} e_3^{\,m_g-2\sigma} e_2^{\,-m_g},\end{aligned}$$

$e_k = e_k(\alpha_{[5]})$, the last integral being the shape integral of two marks (Theorem 3.9) after $v = u/(1-u)$; what is left is the form of $\binom{[5]}{2}$ with $K = e_2$ at the exponent m_g and $\Psi = e_3$ at $2\sigma - m_g$. The masses of $\binom{[5]}{2}$ are then on its own balance wall, $m_{[5]} = 2m_g + 3(2\sigma - m_g)$.

The cousins. The cousins of $\binom{[6]}{3}$ (Proposition 30.20) are its six one-mark contractions $\binom{[6]\setminus\{x\}}{2}$, each a copy of $\binom{[5]}{2}$, the cousin at g being $\binom{[5]}{2}$ itself; the deletion $\binom{[6]\setminus\{x\}}{3}$ is the dual of each, so each has the fusion width one and fuses back into $\binom{[6]}{3}$ with the fusion bunch $\{x\}$ (Proposition 30.20(i)). For any two marks the period is read through either cousin (Proposition 30.20(ii)); at $x = g$ and $y = 5$, writing $s' = m_g$ and renaming g as 5 in the second cousin,

$$\begin{aligned}&\Gamma^{\,2}_{\,1}\begin{bmatrix} s', & 2\sigma - s' \\ & 2\sigma \end{bmatrix} P_{\binom{[5]}{2}}\big(m_1, \dots, m_5; s', 2\sigma - s'\big) \\ &\qquad = \Gamma^{\,2}_{\,1}\begin{bmatrix} m_5, & 2\sigma - m_5 \\ & 2\sigma \end{bmatrix} P_{\binom{[5]}{2}}\big(m_1, m_2, m_3, m_4, s'; m_5, 2\sigma - m_5\big)\end{aligned}$$

on $m_{[5]} + s' = 6\sigma$: the basis exponent s' of $\binom{[5]}{2}$ and the mass of one mark trade places (Proposition 30.20(iii)). At the centre, $\sigma = 1$ and every mass 1, both sides are $\Gamma^{\,2}_{\,1}\begin{bmatrix} 1, & 1 \\ & 2 \end{bmatrix} P_{\binom{[5]}{2}}(\mathbf{1}; 1, 1) = P_{\binom{[5]}{2}}(\mathbf{1}; 1, 1)$, and $P_{\binom{[6]}{3}}(\mathbf{1}; 1, 1) = P_{\binom{[5]}{2}}(\mathbf{1}; 1, 1)$.

The symmetry the fusion adds. All 720 permutations of $[5]\sqcup\{g\}$ carry $\binom{[6]}{3}$; those carrying $\binom{[5]}{2}$, times the permutations of $G = \{g\}$, are the $120\cdot 1$ permutations fixing g. The index is $720/120 = 6 = \binom{n+c}{c} = \binom{6}{1}$ (Remark 30.21).

(4) Two-sums and (5) repair. Every set of two or three marks has the width $2+2-2 = 2$ (Definition 7.12), so $\binom{[5]}{2}$ is prime (Theorem 23.16) and no two-sum, and being fusable it needs no repair.

Answer. The procedure stops at step (3): $\binom{[5]}{2}$ has the fusion width one, passes the tell, and fuses into $\binom{[5]\sqcup\{g\}}{3}$, with the letter $e_3 = \Psi + \alpha_g K$, its only major. Its cousins are the six copies $\binom{[6]\setminus\{x\}}{2}$ of $\binom{[5]}{2}$, and the period of the fusion is one Beta corner times the period of any cousin, the basis exponent of $\binom{[5]}{2}$ and the masses of its marks trading places under the permutations of six marks; the fusion adds the index 6 to the symmetry. □

Chapter 53

Exercises on the motive and the arithmetic of values

The exercises of this chapter work the statements of Chapter 34 on small lists. The list $\binom{[3]}{2}$ at its centre has a pair of width one that does not split off; read at that pair as its root bunch, its period is a node form with two Skeleton values, and it is three times the Trailmoment at the index two of the lattice input that counts $1+3\mathbb{Z}$ and subtracts $2+3\mathbb{Z}$. The list $\binom{[4]}{2}$ is, at the complement of each mark, a core on two marks with a dual pair substituted, and it has the motivic period of $\binom{[3]}{2}$; its pairs have width two and do not split off. The list $\binom{[4]}{1}$ has rational periods and rational motivic periods at its full leans; at its centre a pair of width one has a law with a density, and the period is the critical-line word $\mathrm{crit}_1[1]$, seven times the Trailmoment at the index three of the counting input. Substitutions of dual pairs on five and on eight marks have the motivic periods $(P^{\mathrm{mot}}_{\binom{[3]}{2}})^2$ and $(P^{\mathrm{mot}}_{\binom{[3]}{2}})^3$. At the exponents $(0,2)$ with unit masses every hinge wall and every Beta corner is 1, and the motivic period of a list is the product of the motivic periods of its prime nodes. Every number displayed is exact, and the receipts that recompute them are the scripts named in each solution.

Throughout, a list $\mathcal{B}$ *at its centre* is the family $(\mathcal{B};1,1)$ at the masses $\mathbf{1}$ (Proposition 8.21), and when it is convergent $P^{\mathrm{mot}}_{\mathcal{B}}$ denotes its motivic period (Definition 34.5); a family at a lean is written out with its exponents and its masses.

53.1 Uniform lists at their centres

Exercise 53.1 (The list $\binom{[3]}{2}$ at its centre)**.** Let $\mathcal{E}=\{1,2,3\}$ and $F=\big(\binom{\mathcal{E}}{2};1,1\big)$ at the masses $\mathbf{1}$.

(i) Show that F is convergent (Definition 34.1), that the pair $S=\{1,2\}$ has width one with the ratio $\varrho_S=1/(u(1-u))$ on its shape $(u,1-u)$, and that S does not split off (Theorem 28.25).

(ii) Take a tree of bunches whose root carries the bunch S. Find the Skeleton values of the letters along S, the node form of ω_F at the root (Theorem 34.16) and its share side.

(iii) Evaluate the period $P_{\binom{\mathcal{E}}{2}}(\mathbf{1};1,1)$ as a Trailmoment of a lattice input.

Solution. Receipt: `ex1_series_u23.py`.

(i) *Letters and walls.* The bases are the three pairs, so $K=e_2(\alpha)=\alpha_1\alpha_2+\alpha_1\alpha_3+\alpha_2\alpha_3$ and $\Psi=e_1(\alpha)$ (Definition 7.1), with the rank 2 and the corank 1. The imbalance is $\kappa_{\mathcal{E}}=3-(1\cdot 2+1\cdot 1)=0$ (Definition 8.1). By Theorem 7.13 and Definition 7.12, $d(S)=\min_T|T\cap S|$

and $d^*(S) = |S| - r(S)$: a mark has $d = d^* = 0$, and a pair has $d = 1$ and $d^* = 0$. So the walls $\kappa_S = m_S - d(S) - d^*(S)$ are

$$\kappa_{\{e\}} = 1 - 0 - 0 = 1, \qquad \kappa_{\{e,f\}} = 2 - 1 - 0 = 1,$$

the widths of these sets, as Proposition 8.21(ii) says at a centre. Every proper wall is at least 1, so F is convergent, its motivic period $P^{\mathrm{mot}}_{\binom{[3]}{2}}$ is defined (Definition 34.5), and its period is

$$P_{\binom{\mathcal{E}}{2}}(\mathbf{1}; 1, 1) = \int_{\Delta_{\mathcal{E}}} \frac{d\omega_{\mathcal{E}}(u)}{e_1(u)\, e_2(u)}$$

(Proposition 34.4(ii), Theorem 8.7).

The pair. The bases meet S in one or two marks, so $d(S) = 1$, $r(S) = 2$ and $c(S) = 1$ (Theorem 7.13); every basis contains all but at most one mark of S, so S is a series bunch (Definition 19.1). With the room $R = \{3\}$, the restriction $\mathcal{B}|S$ has the one basis S and the contraction $\mathcal{B}/R$ has the bases $\{1\}$ and $\{2\}$ (Definition 7.5). The hinge values and their ratio (Definition 19.2) are

$$\gamma^K_S = \frac{K_{\mathcal{B}|S}}{K_{\mathcal{B}/R}} = \frac{\alpha_1\alpha_2}{\alpha_1+\alpha_2}, \qquad \gamma^\Psi_S = \frac{\Psi_{\mathcal{B}/R}}{\Psi_{\mathcal{B}|S}} = \frac{\alpha_1+\alpha_2}{1}, \qquad \varrho_S = \frac{\gamma^\Psi_S}{\gamma^K_S} = \frac{(\alpha_1+\alpha_2)^2}{\alpha_1\alpha_2} = \frac{1}{u(1-u)}$$

on the shape $(u, 1-u)$, as Proposition 19.3 gives for a series pair.

The pair does not split off. For one list with $s, t > 0$ and $|S| \geq 2$, Theorem 28.25 says that S is pinned exactly when it has width one and $\mathbf{E}_{\mathcal{B}|S} = \mathbf{E}_{\mathcal{B}/R}$. Here

$$\mathbf{E}_{\mathcal{B}|S} = \alpha_1\alpha_2 \cdot 1, \qquad \mathbf{E}_{\mathcal{B}/R} = (\alpha_1+\alpha_2)(\alpha_1+\alpha_2),$$

which differ: their ratio ϱ_S is at least 4, with equality only at $u = \frac{1}{2}$. So S is not pinned; by Theorem 28.25, (ii), (iii) and (i), it does not split off and its law is carried by no point. This is Corollary 28.26(iv) at the mark 3, whose deletion and contraction are $\mathcal{B} \setminus 3 = \mathcal{B}|S$ and $\mathcal{B}/3 = \mathcal{B}/R$ (Definition 7.3).

(ii) *The step at the root.* The list is one molecule, its circuit $\{1, 2, 3\}$ linking its marks (Definition 7.4), so the root of a tree of bunches is a node, and it may carry the bunch S, of width one, its room being the one mark 3 (Definition 20.7). The flag $\varnothing \subsetneq \mathcal{E}$ has the one step $\mathcal{E}$, which meets S and R: it is a node step of the root (Definition 34.9(ii)), with $Z_B = S$ and $Z_R = R$. The form ω_F is regular on V_F (Proposition 34.4(ii)), and its period is read by its node form at the root (Theorem 34.16(v)). Read $\alpha_S = \rho\,(u, 1-u)$ with $\rho > 0$ and $\alpha_3 = 1$, the one point of Δ_R, and put $Q = u(1-u)$.

Letters and Skeleton values. By Theorem 34.16(i) the letter K is the basis polynomial of $\binom{\mathcal{E}}{2}$, in which S has the floor 1, and Ψ is that of the dual list $\binom{\mathcal{E}}{1}$ (Proposition 7.2), in which S has the floor 0; S has the width 1 in both. Along the scale (Theorem 34.16(ii)),

$$K(\rho u, 1) = \rho^2 u(1-u) + \rho\,\big(u + (1-u)\big) = \rho\, Q\,\big(\rho + Q^{-1}\big), \qquad \Psi(\rho u, 1) = \rho + 1,$$

so the joint spectrum of S is $\{Q^{-1}, 1\}$: the Skeleton value of K is $\xi_K = Q^{-1} = \varrho_S$ and that of Ψ is $\xi_\Psi = 1$. At width one each is the hinge value of the room over that of the bunch (Theorem 34.16(iv), Corollary 19.5): with $\gamma^K_R = K_{\mathcal{B}|R}/K_{\mathcal{B}/S} = \alpha_3/1$ and $\gamma^\Psi_R = \Psi_{\mathcal{B}/S}/\Psi_{\mathcal{B}|R} = \alpha_3/1$ (Definition 19.2), on $\Delta_S \times \Delta_R$

$$\xi_K = \frac{\gamma^K_R}{\gamma^K_S} = \frac{1}{Q}, \qquad \xi_\Psi = \frac{\gamma^\Psi_R}{\gamma^\Psi_S} = \frac{1}{1}.$$

The node form. On the section $\alpha_3 = 1$ the masses are $\mathbf{1}$ and $d\alpha_1\, d\alpha_2 = \rho\, d\rho\, du$ (Lemma 2.7), so (Theorem 8.7)

$$P_{\binom{\varepsilon}{2}}(\mathbf{1}; 1, 1) = \int_0^1 \int_0^\infty \frac{\rho\, d\rho}{K(\rho u, 1)\, \Psi(\rho u, 1)}\, du = \int_0^1 Q^{-1} \int_0^\infty \left(\rho + Q^{-1}\right)^{-1} (\rho + 1)^{-1}\, d\rho\, du.$$

This is the node form of Theorem 34.16(iii) with one term: $A_t = Q^{-1}$, $B_t = 1$, $\nu_t = 1$, the letter exponents $k_{t,K} = k_{t,\Psi} = 1$, and $\mathbf{w}_t = (1, 1)$ on the joint spectrum, $|\mathbf{w}_t| = 2$. Since $0 < \nu_t < |\mathbf{w}_t|$, Sc_t is the convergent scale integral, the stacked Gamma times the Breta of one bunch (Proposition 15.1), and at positive coefficients the Breta is the integral over the shape simplex of J (Definition 3.1, Proposition 15.2):

$$\mathrm{Sc}_t = \Gamma_{\binom{2}{2}}\begin{bmatrix} 1, & 1 \\ 1, & 1 \end{bmatrix} \mathsf{B}^{\{J\}}_{(1,1),\,1;\,I_J}(Q^{-1}, 1) = \int_0^1 \frac{dv}{Q^{-1}v + (1 - v)} = \frac{\log Q^{-1}}{Q^{-1} - 1} = \frac{Q \log Q}{Q - 1}.$$

So

$$P_{\binom{\varepsilon}{2}}(\mathbf{1}; 1, 1) = \int_0^1 A_t\, \mathrm{Sc}_t\, du = \int_0^1 \frac{\log Q}{Q - 1}\, du, \qquad Q = u(1 - u).$$

The share side. Corollary 15.5, with $\xi_0 = 1$, $\xi_1 = Q^{-1}$, $w_0 = w_1 = \kappa = 1$ and one share a on a line $\mathrm{Re}\, a = c$, $0 < c < 1$, writes the term as in Theorem 34.16(iv):

$$\begin{aligned} A_t\, \mathrm{Sc}_t &= Q^{-1}\, \frac{1}{2\pi i} \int_{(c)} \Gamma_{\binom{2}{1}}\begin{bmatrix} a, & 1 - a \\ & 1 \end{bmatrix} \Gamma_{\binom{2}{1}}\begin{bmatrix} 1 - a, & a \\ & 1 \end{bmatrix} \left(Q^{-1}\right)^{a-1} da \\ &= \frac{1}{2\pi i} \int_{(c)} \Gamma_{\binom{4}{0}}\big[a,\ a,\ 1 - a,\ 1 - a\big]\ Q^{-a}\, da. \end{aligned}$$

Here $\xi_K^{-b} = (\gamma_S^K)^b$ with $b = 1 - a$, and the condition of Theorem 34.16(iv) on the bunch, $\int_0^1 Q^{-1} Q^{1-c}\, du < \infty$, holds at $c = \frac{1}{2}$, where it is $\int_0^1 (u(1 - u))^{-1/2} du = \Gamma_{\binom{2}{1}}\begin{bmatrix} \frac{1}{2}, & \frac{1}{2} \\ & 1 \end{bmatrix}$ (Theorem 3.9); the room is one point. Closing to the left (Lemma 5.16(ii), with $X = Q \le \frac{1}{4}$), the stacked Gamma has at $a = -j$, $j \in \mathbb{N}$, the principal part $(a + j)^{-2}$ and no simple part, so the residue there is the derivative of Q^{-a} at $a = -j$, which is $-Q^j \log Q$, and

$$\frac{1}{2\pi i} \int_{(1/2)} \Gamma_{\binom{4}{0}}\big[a,\ a,\ 1 - a,\ 1 - a\big]\ Q^{-a}\, da = -\sum_{j \ge 0} Q^j \log Q = \frac{\log Q}{Q - 1},$$

the value of the node form above.

(iii) *The reflection of the shape.* $\log Q = \log u + \log(1 - u)$, and $1 - Q = 1 - u + u^2$ is unchanged by $u \mapsto 1 - u$; so the two logarithms give equal integrals and

$$P_{\binom{\varepsilon}{2}}(\mathbf{1}; 1, 1) = -2 \int_0^1 \frac{\log u}{1 - u + u^2}\, du.$$

The logarithmic coordinate. With $u = e^{-y}$, $du = -e^{-y} dy$, and multiplying numerator and denominator by $1 + e^{-y}$, since $(1 - z + z^2)(1 + z) = 1 + z^3$,

$$P_{\binom{\varepsilon}{2}}(\mathbf{1}; 1, 1) = 2 \int_0^\infty y\, \frac{e^{-y}}{1 - e^{-y} + e^{-2y}}\, dy = 2 \int_0^\infty y\, \frac{e^{-y} + e^{-2y}}{1 + e^{-3y}}\, dy.$$

The lattice input. Let $\phi = \mathbb{I}_{1+6\mathbb{Z}} + \mathbb{I}_{2+6\mathbb{Z}} - \mathbb{I}_{4+6\mathbb{Z}} - \mathbb{I}_{5+6\mathbb{Z}}$, an input with the density ± 1 on four lattice inputs (Definitions 5.2 and 5.4). It is tame beyond the cut 0, and its Laplace transform there (Definition 5.4) sums its four cosets as geometric series: with $z = e^{-y}$,

$$\mathcal{F}_0(y) = \sum_{k\geq 0} \big(z^{6k+1} + z^{6k+2} - z^{6k+4} - z^{6k+5}\big) = \frac{z + z^2 - z^4 - z^5}{1 - z^6} = \frac{(z+z^2)(1-z^3)}{(1-z^3)(1+z^3)} = \frac{z+z^2}{1+z^3}.$$

Since $\int_{(0,\infty)} x^{-2}\,|\phi|(dx) < \infty$, the Laplace side (Theorem 5.11) at one unit exponent and the index 2 reads $\Gamma(2)\,(\mathsf{T}_{2;(1)}[x]\,\phi)((0,\infty)) = \int_0^\infty y\,\mathcal{F}_0(y)\,dy$, and

$$P_{\binom{\mathcal{E}}{2}}(\mathbf{1};1,1) = 2\,(\mathsf{T}_{2;(1)}[x]\,\big(\mathbb{I}_{1+6\mathbb{Z}} + \mathbb{I}_{2+6\mathbb{Z}} - \mathbb{I}_{4+6\mathbb{Z}} - \mathbb{I}_{5+6\mathbb{Z}}\big))((0,\infty)).$$

Cosets and dilations. $1 + 3\mathbb{Z} = (1+6\mathbb{Z}) \sqcup (4+6\mathbb{Z})$ and $2 + 3\mathbb{Z} = (2+6\mathbb{Z}) \sqcup (5+6\mathbb{Z})$, so

$$\phi = \mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}} + 2\big(\mathbb{I}_{2+6\mathbb{Z}} - \mathbb{I}_{4+6\mathbb{Z}}\big),$$

and the Trailmoment, an integral against its input (Definition 5.1), splits accordingly, every part converging. The dilation $\tau(x) = 2x$ carries $\mathbb{I}_{1+3\mathbb{Z}}$ to $\mathbb{I}_{2+6\mathbb{Z}}$ and $\mathbb{I}_{2+3\mathbb{Z}}$ to $\mathbb{I}_{4+6\mathbb{Z}}$, so transport at one unit exponent (Theorem 5.9 and the paragraph after it) gives

$$(\mathsf{T}_{2;(1)}[x]\,\big(\mathbb{I}_{2+6\mathbb{Z}} - \mathbb{I}_{4+6\mathbb{Z}}\big))((0,\infty)) = 2^{-2}\,(\mathsf{T}_{2;(1)}[x]\,\big(\mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}}\big))((0,\infty)),$$

and

$$P_{\binom{\mathcal{E}}{2}}(\mathbf{1};1,1) = 2\,\big(1+2\cdot 2^{-2}\big)\,(\mathsf{T}_{2;(1)}[x]\,\big(\mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}}\big))((0,\infty)) = 3\,(\mathsf{T}_{2;(1)}[x]\,\big(\mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}}\big))((0,\infty)),$$

which is $2.343907238689458890\ldots$ to eighteen places. The receipt checks the identities of rational functions exactly, the decomposition of the input at every $m \leq 600$, the decomposition and the dilation together on the exact heads $\sum_{m\leq 6N} \phi(m) m^{-2}$, and the integral of the node form against the Trailmoment to twenty-five places.

Answer. F is convergent, with every proper wall 1. The pair $S = \{1,2\}$ is a series bunch of width one with $\gamma_S^K = \alpha_1\alpha_2/(\alpha_1+\alpha_2)$, $\gamma_S^\Psi = \alpha_1 + \alpha_2$ and $\varrho_S = 1/(u(1-u))$; it is not pinned, so it does not split off. At the root bunch S the Skeleton values are Q^{-1} and 1, $Q = u(1-u)$; the node form is $\int_0^1 Q^{-1} \Gamma_2^2 \begin{bmatrix} 1, & 1 \\ 1, & 1 \end{bmatrix} \mathsf{B}^{\{J\}}_{(1,1),1;I_J}(Q^{-1},1)\,du = \int_0^1 \frac{\log Q}{Q-1}\,du$, and its share side reads the stacked Gamma $\Gamma_0^4\big[a,\ a,\ 1-a,\ 1-a\big]$ against Q^{-a}. The period is

$$P_{\binom{[3]}{2}}(\mathbf{1};1,1) = 3\,(\mathsf{T}_{2;(1)}[x]\,\big(\mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}}\big))((0,\infty)).$$

□

Exercise 53.2 (The list $\binom{[4]}{2}$ at its centre)**.** Let $\mathcal{E} = \{1,2,3,4\}$ and $F = \big(\binom{\mathcal{E}}{2}; 1, 1\big)$ at the masses $\mathbf{1}$.

(i) Find the widths and the walls of the sets of marks. Show that the sets of width one with at least two marks are the complements $R = \mathcal{E} \setminus \{e\}$ of single marks, that the cell of each is a dual pair (Definition 21.1), and that $\binom{\mathcal{E}}{2} = \binom{\{e,h\}}{1}\langle e, \mathcal{A}_R\rangle$ with the mark e left in place.

(ii) Show that $P^{\mathrm{mot}}_{\binom{[4]}{2}} = P^{\mathrm{mot}}_{\binom{[3]}{2}}$, and find the period.

(iii) Show that no pair of marks splits off.

Solution. Receipt: `ex2_dualpair_u24.py`.

(i) *Letters, widths, walls.* The complement of a pair is a pair, so $K = \Psi = e_2(\alpha)$ (Definition 7.1). A set S has $r(S) = \min(|S|, 2)$, and by Definition 7.12 its width is $c(S) = r(S) + r(\mathcal{E} \setminus S) - 2$:

$$c(\{e\}) = 1 + 2 - 2 = 1, \qquad c(\{e, f\}) = 2 + 2 - 2 = 2, \qquad c(\mathcal{E} \setminus \{e\}) = 2 + 1 - 2 = 1.$$

At the centre the walls are the widths (Proposition 8.21(ii)): 1, 2 and 1. Every proper wall is at least 1, and F is convergent (Definition 34.1).

The cells. The sets of width one with at least two marks are the triples $R = \mathcal{E} \setminus \{e\}$. The restriction $\mathcal{B}|R$ has the three pairs of R and the contraction $\mathcal{B}/\{e\}$ the three marks of R, the bases through e less e (Definition 7.5). The cell of the bunch R (Theorem 19.4) has the bases of $\mathcal{B}|R = \binom{R}{2}$ and the sets $X + g$, $X \in \mathcal{B}/\{e\} = \binom{R}{1}$:

$$\mathcal{A}_R = \mathcal{B}_R^+ = \binom{R+g}{2}, \qquad \mathcal{A}_R \setminus g = \binom{R}{2}, \qquad \mathcal{A}_R/g = \binom{R}{1}.$$

The complements in R of the pairs of R are its marks, so $\mathcal{A}_R/g$ is the dual table of $\mathcal{A}_R \setminus g$, the weights being 1: the cell is a dual pair (Definition 21.1). The cell of the room $\{e\}$ has the basis $\{e\}$ of $\mathcal{B}|\{e\}$ and the set $\varnothing + g$, $\varnothing$ being the one basis of $\mathcal{B}/R$: it is $\binom{\{e,g\}}{1}$. By Proposition 21.3(iii) the list is the gluing of the two cells, that is $\binom{\{e,h\}}{1}\langle e, \mathcal{A}_R\rangle$ with $\mathcal{A}_R$ at h (Definition 21.1). On the bases: the core basis $\{e\}$ avoids h and takes $X \in \mathcal{A}_R/g$, giving the three pairs through e; the core basis $\{h\}$ takes $X \in \mathcal{A}_R \setminus g$, giving the three pairs of R.

The letters of the substitution. For $e = 4$ and $R = \{1, 2, 3\}$ the cell has $k = K_{\mathcal{A}_R \setminus g} = e_2(\alpha_R)$ and $\psi = \Psi_{\mathcal{A}_R \setminus g} = e_1(\alpha_R)$, and Proposition 21.8(ii) gives the one hinge value $\gamma := \gamma^K_{\mathcal{A}_R} = \gamma^\Psi_{\mathcal{A}_R} = e_2(\alpha_R)/e_1(\alpha_R)$, with $\varrho_{\mathcal{A}_R} = 1$. The mark 4 left in place has $k = \alpha_4$ and $\psi = 1$, so $\pi = e_1(\alpha_R)$, and Proposition 21.8(iii), with $r_{\mathcal{H}} = 1$ and $q = 2$, reads

$$K_{\mathcal{H}}\big(\pi\alpha_4,\ e_2(\alpha_R)\big) = e_1(\alpha_R)\,\alpha_4 + e_2(\alpha_R) = e_2(\alpha) = \pi^0 K, \qquad \Psi_{\mathcal{H}}\big(\pi\alpha_4,\ e_2(\alpha_R)\big) = e_2(\alpha) = \pi^0 \Psi,$$

$K_{\mathcal{H}}$ and $\Psi_{\mathcal{H}}$ both being $x_4 + x_h$.

(ii) *The dual-pair factorization.* Corollary 34.18(a) applies with $q = 1$ at $s = t = 1$. The wall of the cell is

$$\kappa_R = m_R - (s + t)\big(r(R) - 1\big) = 3 - 2\,(2 - 1) = 1,$$

the wall of F at R found above. The pinned family has the form of $(\mathcal{B}|R; \kappa_R, s{+}t{-}\kappa_R) = \big(\binom{R}{2}; 1, 1\big)$ at the masses $\mathbf{1}_R$, and the core is $\big(\binom{\{e,h\}}{1}; 1, 1\big)$ at the masses $m_e = 1$ and $\kappa_R = 1$ at h:

$$P^{\mathrm{mot}}_{\binom{[4]}{2}} = P^{\mathrm{mot}}_{(\binom{\{e,h\}}{1};1,1)} \cdot P^{\mathrm{mot}}_{(\binom{R}{2};1,1)}.$$

The coefficients of the forms show the factorization: with γ as above,

$$\frac{\alpha^{\mathbf{1}}}{K\,\Psi} = \frac{\alpha_4\,\gamma}{(\alpha_4 + \gamma)^2} \cdot \frac{\alpha^{\mathbf{1}_R}}{e_1(\alpha_R)\,e_2(\alpha_R)},$$

the coefficient of the core at (α_4, γ) times that of $\big(\binom{R}{2}; 1, 1\big)$, an identity of rational functions.

The core. The core is a family on two marks with both letters $\alpha_e + \alpha_h$ and the walls $\kappa_{\{e\}} = \kappa_{\{h\}} = 1$; its form is $\Omega/(\alpha_e + \alpha_h)^2$, and by Lemma S18 its motivic period is its Beta corner,

$$P^{\mathrm{mot}}_{(\binom{\{e,h\}}{1};1,1)} = \Gamma_{\!2}\begin{bmatrix} 1,\ 1 \\ 2 \end{bmatrix} = \frac{\Gamma(1)\,\Gamma(1)}{\Gamma(2)} = 1.$$

The pinned family $\binom{R}{2};1,1)$ at $\mathbf{1}_R$ is $\binom{[3]}{2}$ at its centre with its marks named by R; renaming the coordinates is an isomorphism of the models that maps the positive cells and the forms onto each other, so the two have one motivic period (Lemma 34.7). Hence

$$P^{\mathrm{mot}}_{\binom{[4]}{2}} = P^{\mathrm{mot}}_{\binom{[3]}{2}}, \qquad \mathrm{C}\big(P^{\mathrm{mot}}_{\binom{[4]}{2}}\big) = \mathrm{C}\big(P^{\mathrm{mot}}_{\binom{[3]}{2}}\big),$$

and by Exercise 53.1 the period is $P_{\binom{[4]}{2}}(\mathbf{1};1,1) = 3\,(\mathsf{T}_{2;(1)}[x]\,(\mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}}))((0,\infty))$.

(iii) *The pairs.* A pair has width two in the one active table, so by Corollary 28.26(i) it does not split off, and its law is carried by no point. The list is connected and its only sets with two marks on each side are the pairs, so it is prime (Theorem 23.16), and Corollary 28.26(ii) says the same. The complements of the marks do split off, as in (ii): $\mathbf{E}_{\mathcal{B}\setminus e} = e_2(\alpha_R)\,e_1(\alpha_R) = \mathbf{E}_{\mathcal{B}/e}$ (Corollary 28.26(iv)).

Answer. The marks and the triples have width one and the pairs width two, and at the centre these are the walls. Every triple $R = \mathcal{E}\setminus\{e\}$ has the cell $\binom{R+g}{2}$, a dual pair, and $\binom{\mathcal{E}}{2} = \binom{\{e,h\}}{1}\langle e, \binom{R+g}{2}\rangle$. With $\kappa_R = 1$, the core on two marks has the motivic period $\Gamma^{\,2}_{\,1}\left[\begin{matrix}1,\ 1\\ 2\end{matrix}\right] = 1$, so

$$P^{\mathrm{mot}}_{\binom{[4]}{2}} = P^{\mathrm{mot}}_{\binom{[3]}{2}}, \qquad P_{\binom{[4]}{2}}(\mathbf{1};1,1) = 3\,(\mathsf{T}_{2;(1)}[x]\,(\mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}}))((0,\infty)).$$

No pair splits off: pairs have width two. □

Exercise 53.3 (The list $\binom{[4]}{1}$ at its full leans and at its centre)**.** Let $\mathcal{E} = \{1,2,3,4\}$ and $\mathcal{B} = \binom{\mathcal{E}}{1}$.

(i) Show that at its full leans $(s,0)$ and $(0,t)$, at positive integer masses on the balance wall with every proper wall at least 1, the periods are rational, and so are the motivic periods.

(ii) At the centre, show that $S = \{3,4\}$ has width one, find its hinge values and its law (Definition 28.5), and show that the law is not a point mass.

(iii) Read the period at the root bunch S, write it on the share side of the node form, show that it is the critical-line word $\mathrm{crit}_1[1]$ (Definition 36.3), and evaluate it.

Solution. Receipt: `ex3_critical_u14.py`.

(i) *Counts.* The bases are the four marks, so $K = e_1(\alpha)$ and $\Psi = e_3(\alpha)$ (Definition 7.1), of the rank 1 and the corank 3. A proper set S has $d(S) = 0$, a basis avoiding it, $r(S) = 1$, $d^*(S) = |S|-1$ and $c(S) = 1$ (Theorem 7.13, Definition 7.12).

The full lean $(s,0)$. The balance wall is $m_{\mathcal{E}} = s$, and the walls are $\kappa_S = m_S - s\,d(S) = m_S$ (Definition 8.1), at least 1 at positive integer masses. On the shape simplex $K(u) = |u| = 1$, so (Theorems 8.7 and 3.9)

$$P_{\mathcal{B}}(\mathbf{m};s,0) = \int_{\Delta_{\mathcal{E}}} u^{\mathbf{m-1}}\,d\omega_{\mathcal{E}}(u) = \Gamma^{\,4}_{\,1}\left[\begin{matrix}m_1,\ m_2,\ m_3,\ m_4\\ s\end{matrix}\right],$$

a positive rational number; at $(4,0)$ and the masses $\mathbf{1}$ it is $\Gamma^{\,4}_{\,1}\left[\begin{matrix}1,\ 1,\ 1,\ 1\\ 4\end{matrix}\right] = \frac{1}{6}$.

The full lean $(0,t)$. The balance wall is $m_{\mathcal{E}} = 3t$. By Corollary 34.8, with $2\sigma = t$, the family $(\mathcal{B};0,t)$ at $\mathbf{m}$ has the motivic period of $(\mathcal{B};t,0)$ at $t\mathbf{1}-\mathbf{m}$, whose total is $4t-3t = t$ and whose walls are those of $(\mathcal{B};0,t)$ at the complements, so

$$P_{\mathcal{B}}(\mathbf{m};0,t) = \Gamma^{\,4}_{\,1}\left[\begin{matrix}t-m_1,\ t-m_2,\ t-m_3,\ t-m_4\\ t\end{matrix}\right],$$

rational again; the walls of $(\mathcal{B};0,t)$ at the complements of the marks are $t-m_e\ge 1$.

The motivic periods. The set $\{3,4\}$ has width one with two marks on each side, and by Proposition 21.3(iii) the list is the gluing of its two cells: the cell of the bunch has the bases $\{3\},\{4\}$ of $\mathcal{B}|\{3,4\}$ and g, the one basis of $\mathcal{B}/\{1,2\}$ being $\varnothing$, and the cell of the room has the bases $\{1\},\{2\},\{g\}$. Both are the parallel nodes $\binom{\{3,4,g\}}{1}$ and $\binom{\{1,2,g\}}{1}$ on three marks, so the splitting of Corollary 34.18(b) has no prime node, and at either full lean P_F^{mot} is a positive rational number c. Its period is c, so $c=P_F$: the motivic periods are the rational numbers displayed.

(ii) *The centre.* At $(1,1)$ and the masses $\mathbf{1}$ every proper wall is the width 1 (Proposition 8.21(ii)), and $F=(\mathcal{B};1,1)$ is convergent. The pair $S=\{3,4\}$, with the room $S'=\{1,2\}$, has width one, and no basis contains both of its marks: it is a parallel bunch (Definition 19.1). The restriction $\mathcal{B}|S$ has the bases $\{3\},\{4\}$, and the contraction $\mathcal{B}/S'$, the bases meeting S' in one mark less that mark, has the one basis $\varnothing$ (Definition 7.5), whose complement in S is S. So (Definition 19.2, Proposition 19.3)

$$\gamma_S^K=\frac{\alpha_3+\alpha_4}{1},\qquad \gamma_S^\Psi=\frac{\alpha_3\alpha_4}{\alpha_3+\alpha_4},\qquad \varrho_S=\frac{\alpha_3\alpha_4}{(\alpha_3+\alpha_4)^2}=u(1-u)$$

on the shape $(u,1-u)$ of S, and likewise $\varrho_{S'}=u'(1-u')$ on the shape $(u',1-u')$ of S'.

The law. At width one the stations of the room are D_0 and D_1, of the excesses 0 and 1, and the seam letters are the letters of $\mathcal{B}/S'$ and of $\mathcal{B}|S$ (Proposition 28.3(ii)):

$$V_{D_0}=K_{\mathcal{B}/S'}=1,\qquad V_{D_1}=K_{\mathcal{B}|S}=\alpha_3+\alpha_4,$$
$$V^*_{D_0}=\Psi_{\mathcal{B}/S'}=\alpha_3\alpha_4,\qquad V^*_{D_1}=\Psi_{\mathcal{B}|S}=\alpha_3+\alpha_4.$$

With $d(S)=0$ and $d^*(S)=1$ the wall of the piece is $\kappa_S=2-(1\cdot 0+1\cdot 1)=1$ and its top wall is $(1+1)\cdot 1-1=1$ (Definition 28.4). Definition 28.5 gives the scale, the scale form on the shape $(u,1-u)$, and the seam vector $(\varrho^\rho_{D_0},\varrho^\rho_{D_1},\varrho^{\rho*}_{D_0},\varrho^{\rho*}_{D_1})$:

$$\gamma_S^\rho=\Big(\frac{\alpha_3+\alpha_4}{1}\Big)^{1/2}\Big(\frac{\alpha_3\alpha_4}{\alpha_3+\alpha_4}\Big)^{1/2}=(\alpha_3\alpha_4)^{1/2},$$
$$\phi_S^\rho(du)=1^{-1}\big(u+(1-u)\big)^{-1}\big(u(1-u)\big)^{-1/2}\,du=\varrho_S^{-1/2}\,du,$$
$$\boldsymbol{\varrho}_S^\rho=\Big(1,\ \frac{\alpha_3+\alpha_4}{(\alpha_3\alpha_4)^{1/2}},\ \frac{\alpha_3\alpha_4}{(\alpha_3+\alpha_4)(\alpha_3\alpha_4)^{1/2}},\ 1\Big)=\big(1,\ \varrho_S^{-1/2},\ \varrho_S^{1/2},\ 1\big).$$

The seam torus is cut out by $x_{D_0}=1$, $x^*_{D_1}=1$ and $x_{D_1}x^*_{D_0}=1$: it is the curve of the points $(1,x,x^{-1},1)$, $x>0$. The law is the image of $\varrho_S^{-1/2}du$ under $x=\varrho_S^{-1/2}=(u(1-u))^{-1/2}$. Since $u(1-u)\le\frac14$ it is carried by $x\ge 2$; each $x>2$ has the two preimages u and $1-u$, with $(1-2u)\,du=-2x^{-3}dx$ and $|1-2u|=(1-4x^{-2})^{1/2}$, so the law is

$$\frac{4\,dx}{x\,(x^2-4)^{1/2}}\quad\text{on } x>2,\qquad \text{of total mass } \int_0^1\big(u(1-u)\big)^{-1/2}du=\Gamma\begin{matrix}2\\1\end{matrix}\Big[\begin{matrix}\frac12,\ \frac12\\1\end{matrix}\Big]$$

(Theorem 3.9). It has a density, so it is not a point mass. Theorem 28.25 says the same through the hinge values: $\mathbf{E}_{\mathcal{B}|S}=(\alpha_3+\alpha_4)^2$ and $\mathbf{E}_{\mathcal{B}/S'}=\alpha_3\alpha_4$ differ, ϱ_S not being constant, so S is not pinned and does not split off.

(iii) *The node form at the root bunch S.* As in Exercise 53.1(ii), a tree of bunches whose root carries S has the step $\mathcal{E}$ as a node step of the root (Definition 34.9(ii)), and the period is read by the node form there (Theorem 34.16(v)). Read $\alpha_S=\rho\,(u,1-u)$ and $\alpha_{S'}=(u',1-u')$ on the section $\alpha_1+\alpha_2=1$; then $d\alpha_3\,d\alpha_4=\rho\,d\rho\,du$ (Lemma 2.7) and

$$K(\rho u,u')=\rho+1,\qquad \Psi(\rho u,u')=\rho\,u'(1-u')+\rho^2u(1-u)=\rho\,\varrho_S\Big(\rho+\frac{\varrho_{S'}}{\varrho_S}\Big):$$

the Skeleton values (Theorem 34.16(ii)) are $\xi_K = 1$ and $\xi_\Psi = \varrho_{S'}/\varrho_S = \gamma^\Psi_{S'}/\gamma^\Psi_S$, the hinge value of the room over that of the bunch on $\Delta_S \times \Delta_{S'}$ (Theorem 34.16(iv)). By Theorem 8.7,

$$P_{\mathcal{B}}(\mathbf{1}; 1, 1) = \int_{\Delta_S \times \Delta_{S'}} \int_0^\infty \frac{d\rho}{(\rho+1)\,(\varrho_S\,\rho + \varrho_{S'})}\, d\omega_S(u)\, d\omega_{S'}(u'),$$

the node form with one term: $A_t = \varrho_S^{-1}$, $B_t = 1$, $\nu_t = 1$ and $\mathbf{w}_t = (1,1)$, so that $\mathrm{Sc}_t = \Gamma_{\,2}^{\,2}\!\begin{bmatrix} 1,\ 1 \\ 1,\ 1 \end{bmatrix} \mathsf{B}^{\{J\}}_{(1,1),\,1;\,I_J}\big(1, \varrho_{S'}/\varrho_S\big)$: the bunch and the room meet through the one Skeleton value $\varrho_{S'}/\varrho_S$.

The share side. Corollary 15.5, with $\xi_0 = 1$, $\xi_1 = \varrho_{S'}/\varrho_S$ and one share a, writes the term as

$$\begin{aligned} A_t\,\mathrm{Sc}_t &= \varrho_S^{-1}\,\frac{1}{2\pi i}\int_{(c)} \Gamma_{\,0}^{\,4}\big[a,\ a,\ 1-a,\ 1-a\big]\,\Big(\frac{\varrho_{S'}}{\varrho_S}\Big)^{a-1} da \\ &= \frac{1}{2\pi i}\int_{(c)} \Gamma_{\,0}^{\,4}\big[a,\ a,\ 1-a,\ 1-a\big]\ \varrho_S^{-a}\,\varrho_{S'}^{a-1}\, da. \end{aligned}$$

On the line $\mathrm{Re}\,a = \frac12$ the two conditions of Theorem 34.16(iv) are $\int_{\Delta_S} \varrho_S^{-1/2} d\omega_S < \infty$ and $\int_{\Delta_{S'}} \varrho_{S'}^{-1/2} d\omega_{S'} < \infty$, both $\Gamma_{\,1}^{\,2}\!\begin{bmatrix} \frac12,\ \frac12 \\ 1 \end{bmatrix}$; so the bunch and the room separate under the share integral, and by Theorem 3.9, for $0 < \mathrm{Re}\,a < 1$,

$$\int_0^1 \big(u(1-u)\big)^{-a} du = \Gamma_{\,1}^{\,2}\!\begin{bmatrix} 1-a,\ 1-a \\ 2-2a \end{bmatrix}, \qquad \int_0^1 \big(u'(1-u')\big)^{a-1} du' = \Gamma_{\,1}^{\,2}\!\begin{bmatrix} a,\ a \\ 2a \end{bmatrix}.$$

So

$$P_{\mathcal{B}}(\mathbf{1}; 1, 1) = \frac{1}{2\pi i}\int_{(1/2)} \Gamma_{\,0}^{\,4}\big[a,\ a,\ 1-a,\ 1-a\big]\ \Gamma_{\,1}^{\,2}\!\begin{bmatrix} 1-a,\ 1-a \\ 2-2a \end{bmatrix}\ \Gamma_{\,1}^{\,2}\!\begin{bmatrix} a,\ a \\ 2a \end{bmatrix}\, da :$$

the moments of the orders $-a$ and $a-1$ of the two ratios of hinge values, paired over one share. This is the one-share display of Theorem 19.13 at the level shares $a^d = b^d = a$ and $a^r = b^r = 1-a$, the bunch family and the room family having these two Beta corners as periods: the even share $\sigma^d = a$ is free and the odd share is 0.

The critical-line word. By the reflection at a and at $2a$ and the shift $\Gamma(2-2a) = (1-2a)\,\Gamma(1-2a)$ (Proposition 1.3(iii),(v)),

$$\Gamma_{\,1}^{\,2}\!\begin{bmatrix} a,\ a \\ 2a \end{bmatrix} \Gamma_{\,1}^{\,2}\!\begin{bmatrix} 1-a,\ 1-a \\ 2-2a \end{bmatrix} = \frac{\Gamma_{\,0}^{\,4}\big[a,\ a,\ 1-a,\ 1-a\big]}{(1-2a)\,\Gamma_{\,0}^{\,2}\big[2a,\ 1-2a\big]} = \frac{\pi^2}{\sin^2 \pi a} \cdot \frac{\sin 2\pi a}{\pi\,(1-2a)} = \frac{2\pi \cot \pi a}{1-2a},$$

and $\partial_a \Gamma_{\,0}^{\,4}\big[a,\ a,\ 1-a,\ 1-a\big] = \partial_a\big(\pi^2/\sin^2 \pi a\big) = -2\pi \cot \pi a \cdot \Gamma_{\,0}^{\,4}\big[a,\ a,\ 1-a,\ 1-a\big]$. So

$$P_{\mathcal{B}}(\mathbf{1}; 1, 1) = -\frac{1}{2\pi i}\int_{(1/2)} \frac{\partial_a \Gamma_{\,0}^{\,4}\big[a,\ a,\ 1-a,\ 1-a\big]}{1-2a}\, da = \mathrm{crit}_1[1],$$

Definition 36.3 at $k = 1$ and $R = 1$, where $-\frac{2}{(2k)!} = -1$.

Closing. The integrand is holomorphic on $0 < \mathrm{Re}\,a < 1$, regular at $a = \frac12$ (Definition 36.3), and on every vertical line of the strip it is $O(e^{-2\pi|\,\mathrm{Im}\,a|})$, since $|\sin \pi a|^2 = \sin^2 \pi\,\mathrm{Re}\,a + \sinh^2 \pi\,\mathrm{Im}\,a$; so

the line moves to $\operatorname{Re} a = c$ with $\frac{1}{2} < c < 1$, and an integration by parts, with no boundary terms, gives

$$P_{\mathcal{B}}(\mathbf{1};1,1) = \frac{1}{2\pi i}\int_{(c)} \Gamma_{\,0}^{4}\big[a,\ a,\ 1-a,\ 1-a\big]\ g(a)\,da, \qquad g(a) = \partial_a \frac{1}{1-2a} = \frac{2}{(1-2a)^2}.$$

The function g is rational, holomorphic on $\operatorname{Re} a \geq c$, and $O(|a|^{-2})$, so the right closing of Lemma 5.16(i) applies: with $g'(a) = 8(1-2a)^{-3}$,

$$P_{\mathcal{B}}(\mathbf{1};1,1) = -\sum_{m\geq 1} g'(m) = \sum_{m\geq 1} \frac{8}{(2m-1)^3} = \sum_{m\geq 1} \Big(m - \frac{1}{2}\Big)^{-3}.$$

(Closed directly, the integrand $-\partial_a \Gamma_{\,0}^{4}\big[a,\ a,\ 1-a,\ 1-a\big]/(1-2a)$ has at $a = m \geq 1$ a pole of order three with the residue $8(1-2m)^{-3}$; the receipt checks $m \leq 6$.)

The Trailmoment. At one unit exponent and the coefficient function x the last sum is $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac{1}{2}+\mathbb{Z}})((0,\infty))$ (Definition 5.2). The lattice relation at the step 2 (Theorem 5.12(i), $q = 2$, $b = 0$, the cut 0) assembles $\frac{1}{2}\mathbb{Z}$ from the cosets $\mathbb{Z}$ and $\frac{1}{2}+\mathbb{Z}$, the coefficient function $x/2$ multiplying the kernel by 2^3:

$$(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) + (\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac{1}{2}+\mathbb{Z}})((0,\infty)) = 2^3\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)).$$

So $P_{\mathcal{B}}(\mathbf{1};1,1) = (\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac{1}{2}+\mathbb{Z}})((0,\infty)) = 7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$, which is $\mathrm{crit}_1[1]$ of Theorem 36.8; it is $8.414398322117159997\ldots$ to eighteen places. The receipt checks the relation on the exact heads $\sum_{m\leq N}(m-\frac{1}{2})^{-3} + \sum_{m\leq N} m^{-3} = 8\sum_{k\leq 2N} k^{-3}$ and the share integral against $7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ to twenty-five places. At a full lean one letter is active with one Skeleton value, no share is free, and the period is rational, by (i); at the centre the one free share runs over the critical line and carries a Trailmoment of the odd index three.

Answer. At $(s,0)$ the period is $\Gamma_{\,1}^{4}\begin{bmatrix}\mathbf{m}\\ s\end{bmatrix}$ and at $(0,t)$ it is $\Gamma_{\,1}^{4}\begin{bmatrix}t\mathbf{1}-\mathbf{m}\\ t\end{bmatrix}$, rational, and the motivic periods are these rational numbers, the list having no prime node. At the centre $S = \{3,4\}$ is a parallel bunch of width one with $\gamma_S^K = \alpha_3+\alpha_4$, $\gamma_S^\Psi = \alpha_3\alpha_4/(\alpha_3+\alpha_4)$ and $\varrho_S = u(1-u)$; its law is $4\,dx/(x(x^2-4)^{1/2})$ on the points $(1,x,x^{-1},1)$, $x > 2$, of its seam torus, not a point mass. Read at the root bunch S,

$$\begin{aligned} P_{\binom{[4]}{1}}(\mathbf{1};1,1) &= \frac{1}{2\pi i}\int_{(1/2)} \Gamma_{\,0}^{4}\big[a,\ a,\ 1-a,\ 1-a\big]\,\Gamma_{\,1}^{2}\begin{bmatrix}1-a,\ 1-a\\ 2-2a\end{bmatrix}\Gamma_{\,1}^{2}\begin{bmatrix}a,\ a\\ 2a\end{bmatrix}\,da \\ &= \mathrm{crit}_1[1] = 7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)). \end{aligned}$$

□

53.2 Substitutions of dual pairs

Exercise 53.4 (Substitutions on five and on eight marks)**.** Let $\mathrm{P}_5 = \binom{\{1,2,h\}}{1}\langle 1,2,\mathcal{A}\rangle$, the marks $1,2$ left in place and the cell $\mathcal{A} = \binom{\{3,4,5,g\}}{2}$ at h, and let $\mathrm{M}_8 = \binom{\{b_1,b_2,h_1,h_2\}}{2}\langle b_1,b_2,\mathcal{A}_1,\mathcal{A}_2\rangle$, the marks b_1,b_2 left in place and the cells $\mathcal{A}_i = \binom{\{x_i,y_i,z_i,g_i\}}{2}$ at h_i, with $R = \{3,4,5\}$, $R_i = \{x_i,y_i,z_i\}$ and $B = \{b_1,b_2\}$ (Definition 21.1).

(i) Find the bases of P_5, show that its cell is a dual pair and that P_5 is convergent at its centre, and find its motivic period there.

(ii) Find the rank of M_8, the widths of R_1, R_2 and B, and its letters; show that it is convergent at its centre and find its motivic period there. What becomes of the bunch B?

Solution. Receipt: `ex4_substitution.py`, with the helper `subst.py`.

(i) *The bases.* By Definition 21.1, the core bases $\{1\}$ and $\{2\}$ avoid h and take a basis of $\mathcal{A}/g = \binom{R}{1}$, and the core basis $\{h\}$ takes a basis of $\mathcal{A} \setminus g = \binom{R}{2}$: the bases of P_5 are the six pairs $\{1,x\},\{2,x\}$, $x \in R$, and the three pairs of R, all the pairs of $\{1,\dots,5\}$ but $\{1,2\}$, and its rank is $1+(2-1)=2$ (Proposition 21.3(i)). The complements in R of the pairs of R are its marks, so $\mathcal{A}/g$ is the dual of $\mathcal{A} \setminus g$: the cell is a dual pair, and by Proposition 21.8(ii) both letters read it through the one hinge value $\gamma = e_2(\alpha_R)/e_1(\alpha_R)$. By Theorem 21.4, with $K_{\mathcal{A}/g} = \Psi_{\mathcal{A}\setminus g} = e_1(\alpha_R)$,

$$K = e_1(\alpha_R)\,\big(\alpha_1+\alpha_2+\gamma\big), \qquad \Psi = e_1(\alpha_R)\,\big(\alpha_1\alpha_2+(\alpha_1+\alpha_2)\,\gamma\big).$$

Walls. R is a bunch of width one with the cell $\mathcal{A}$ (Proposition 21.3(i)); its wall at the centre is $\kappa_R = m_R-(s+t)(r(R)-1) = 3-2\cdot 1 = 1$, $r(R)=2$ (Corollary 34.18(a)), and $2\sigma-\kappa_R = 1$. Both letters read R through γ, so by Theorem 19.9(iii) P_5 has every proper wall positive exactly when its two cell families do: $(\mathcal{A};1,1)$ at the masses $(\mathbf{1}_R,1)$, which is $\binom{[4]}{2}$ at its centre, and $\big(\binom{\{1,2,h\}}{1};1,1\big)$ at the masses $(1,1,\kappa_R)=\mathbf{1}$, which is $\binom{[3]}{1}$ at its centre; both are connected, and their walls are their widths (Proposition 8.21(ii)). So every proper wall of P_5 is positive, an integer and so at least 1 (the receipt finds the values 1 and 2), and P_5 is convergent at its centre.

The motivic period. Corollary 34.18(a) with $q=1$:

$$P^{\mathrm{mot}}_{\mathrm{P}_5} = P^{\mathrm{mot}}_{(\binom{\{1,2,h\}}{1};1,1)} \cdot P^{\mathrm{mot}}_{(\binom{R}{2};1,1)},$$

the core at the masses $\mathbf{1}$ and the pinned family $(\mathcal{B}|R;\kappa_R,2-\kappa_R) = \big(\binom{R}{2};1,1\big)$ at $\mathbf{1}_R$. The core has the letters e_1 and e_2 of $\alpha_1,\alpha_2,\alpha_h$, so its form is $\Omega/(e_1e_2)$, the form of $\binom{[3]}{2}$ at its centre, whose letters are e_2 and e_1; the pinned family is $\binom{[3]}{2}$ at its centre on the marks of R. Two convergent families with one form have one motivic period (Lemma 34.7, with the renaming of the coordinates), so

$$P^{\mathrm{mot}}_{\mathrm{P}_5} = \big(P^{\mathrm{mot}}_{\binom{[3]}{2}}\big)^2,$$

the two factors being one motivic period. In coefficients,

$$\frac{\alpha^{\mathbf{1}}}{K\,\Psi} = \frac{\alpha_1\alpha_2\,\gamma}{e_1(\alpha_1,\alpha_2,\gamma)\,e_2(\alpha_1,\alpha_2,\gamma)} \cdot \frac{\alpha^{\mathbf{1}_R}}{e_1(\alpha_R)\,e_2(\alpha_R)},$$

the core at $(\alpha_1,\alpha_2,\gamma)$ times $\binom{[3]}{2}$ on R.

(ii) *Rank and widths.* By Proposition 21.3(i) M_8 is a list of rank $2+(2-1)+(2-1)=4$ on eight marks, and each R_i is a bunch of width one with the cell $\mathcal{A}_i$; from the six core bases, with three choices at each cell, it has $6\cdot 3\cdot 3 = 54$ bases. The pairs of the core meet B in 0, 1 or 2 marks, so B has the width two in the core, and by Corollary 21.11 in M_8.

Letters. Both cells are dual pairs with $k_i = e_2(\alpha_{R_i})$, $\psi_i = e_1(\alpha_{R_i})$ and the hinge values $\gamma_i = e_2(\alpha_{R_i})/e_1(\alpha_{R_i})$, and the marks left in place have $k=\alpha_b$, $\psi=1$ (Proposition 21.8(ii),(iii)). With $\pi = e_1(\alpha_{R_1})\,e_1(\alpha_{R_2})$, $r_{\mathcal{H}}=2$ and $q=4$, Proposition 21.8(iii) gives, $K_{\mathcal{H}} = \Psi_{\mathcal{H}} = e_2$ being homogeneous of degree two,

$$\pi^2\,e_2(\alpha_{b_1},\alpha_{b_2},\gamma_1,\gamma_2) = \pi\,K, \qquad \pi^2\,e_2(\alpha_{b_1},\alpha_{b_2},\gamma_1,\gamma_2) = \pi^{4-2-1}\,\Psi,$$

so $K=\Psi = e_1(\alpha_{R_1})\,e_1(\alpha_{R_2})\,e_2(\alpha_{b_1},\alpha_{b_2},\gamma_1,\gamma_2)$: M_8 is identically self-dual, its cobases being its bases.

Walls. The walls of the cells are $\kappa_{R_i} = 3-2\,(2-1) = 1$ (Corollary 34.18(a)). Theorem 19.9(iii), at R_1 and then at R_2 in the cell of the room, both letters reading each R_i through γ_i, reduces the positivity of the walls to that of the three families $(\mathcal{A}_1; 1, 1)$, $(\mathcal{A}_2; 1, 1)$ and $(\binom{\{b_1,b_2,h_1,h_2\}}{2}; 1, 1)$, all at the masses $\mathbf{1}$ (the hinges carrying $2\sigma - \kappa_{R_i} = 1$ and $\kappa_{R_i} = 1$): three copies of $\binom{[4]}{2}$ at its centre, convergent by Exercise 53.2. So M_8 is convergent at its centre; its 254 proper walls are positive integers (the receipt lists them, the least being 1).

The motivic period. Corollary 34.18(a) with $q = 2$, the pinned families $\big(\binom{R_i}{2}; 1, 1\big)$ at $\mathbf{1}_{R_i}$ and the core $\binom{\{b_1,b_2,h_1,h_2\}}{2}$ at its centre:

$$P^{\mathrm{mot}}_{\mathrm{M}_8} = P^{\mathrm{mot}}_{\binom{[4]}{2}} \cdot \big(P^{\mathrm{mot}}_{\binom{[3]}{2}}\big)^2 = \big(P^{\mathrm{mot}}_{\binom{[3]}{2}}\big)^3,$$

the second equality by Exercise 53.2(ii), every factor at its centre. In coefficients,

$$\frac{\alpha^{\mathbf{1}}}{K\,\Psi} = \frac{\alpha_{b_1}\alpha_{b_2}\,\gamma_1\gamma_2}{e_2(\alpha_{b_1},\alpha_{b_2},\gamma_1,\gamma_2)^2} \cdot \prod_{i=1}^{2} \frac{\alpha^{\mathbf{1}_{R_i}}}{e_1(\alpha_{R_i})\,e_2(\alpha_{R_i})}.$$

The bunch B. B is left in place and keeps in M_8 the width two it has in the core (Theorem 34.17(v)); by Corollary 28.26(i) it does not split off and enters the period through a law carried by no point. The cells split off around it, and B goes whole into the core $\binom{[4]}{2}$, which splits further only at the complement of a single mark, a set of width one (Exercise 53.2). Along B, $K(\tau\alpha_B, \alpha_{R_1}, \alpha_{R_2}) = \pi\, e_2(\tau\alpha_{b_1}, \tau\alpha_{b_2}, \gamma_1, \gamma_2)$, so the Skeleton values of B in M_8 are those of the pair $\{1, 2\}$ of $\binom{[4]}{2}$ at the point $(\alpha_{b_1}, \alpha_{b_2}, \gamma_1, \gamma_2)$.

Answer. P_5 has as its bases the pairs of $\{1, \dots, 5\}$ other than $\{1, 2\}$, its cell $\binom{\{3,4,5,g\}}{2}$ is a dual pair, and $P^{\mathrm{mot}}_{\mathrm{P}_5} = (P^{\mathrm{mot}}_{\binom{[3]}{2}})^2$. M_8 has the rank 4; R_1, R_2 have width one and B width two; $K = \Psi = e_1(\alpha_{R_1})e_1(\alpha_{R_2})\,e_2(\alpha_{b_1}, \alpha_{b_2}, \gamma_1, \gamma_2)$, and $P^{\mathrm{mot}}_{\mathrm{M}_8} = (P^{\mathrm{mot}}_{\binom{[3]}{2}})^3$. So

$$P_{\mathrm{P}_5}(\mathbf{1}; 1, 1) = \Big(3\,(\mathsf{T}_{2;(1)}[x]\,(\mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}}))((0,\infty))\Big)^2,$$
$$P_{\mathrm{M}_8}(\mathbf{1}; 1, 1) = \Big(3\,(\mathsf{T}_{2;(1)}[x]\,(\mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}}))((0,\infty))\Big)^3,$$

with $\mathrm{C}(P^{\mathrm{mot}}_{\mathrm{P}_5}) \subseteq \mathrm{C}(P^{\mathrm{mot}}_{\binom{[3]}{2}}) \cdot \mathrm{C}(P^{\mathrm{mot}}_{\binom{[3]}{2}})$, and likewise with three factors for M_8 (Theorem 34.17(ii)). The bunch B of width two does not split off and goes whole into the core. □

53.3 Full leans

Exercise 53.5 (Full leans at the exponents $(0, 2)$)**.** Let $F = (\mathcal{B}; 0, 2)$ be a convergent family of one list on $\mathcal{E}$, $|\mathcal{E}| \geq 3$, at the masses $\mathbf{1}$ (Definition 34.1).

(i) Show that $|\mathcal{E}| = 2r$ and that $\kappa_S = 2r(S) - |S|$. At a set R of width one with at least two marks on each side, show that the two hinge walls κ_R and $\kappa_{\mathcal{E}\setminus R}$ are 1, that both cell families have the masses $\mathbf{1}$, and that the Beta corner of the split is 1.

(ii) Show that every node of the splitting of Corollary 34.18(b) is prime and that $P^{\mathrm{mot}}_F = \prod_v P^{\mathrm{mot}}_{F_v}$, every $F_v = (\mathcal{H}_v; 0, 2)$ at the masses $\mathbf{1}$.

(iii) Let T_6 be the list of rank three on $\{1, \dots, 6\}$ whose bases are the nineteen triples other than $\{1, 2, 3\}$, let $\mathcal{T}$ be the cell T_6 on $\{1, \dots, 5\} \sqcup \{g\}$ with the mark 6 as its hinge g, let $\mathcal{T}'$ be

a copy of it on $\{1',\dots,5'\}\sqcup\{g\}$, and let $\mathrm{D}_{10}=\mathcal{T}\oplus_g\mathcal{T}'$ (Lemma 21.12). Find the motivic period of $(\mathrm{D}_{10};0,2)$ at the masses $\mathbf{1}$, and decide whether $\{1',\dots,5'\}$ splits off at the centre and at $(0,2)$.

Solution. Receipt: `ex5_fulllean.py`, with the helper `subst.py`.

(i) *Balance and walls.* At $(0,2)$ only Ψ is active, $\sigma=\frac{0+2}{2}=1$, and the imbalance is $\kappa_{\mathcal{E}}=n-2\,(n-r)=2r-n$ (Definition 8.1); on the balance wall $n=2r$. The walls are $\kappa_S=m_S-2\,d^*(S)$ with $d^*(S)=|S|-r(S)$ (Definition 7.12), so

$$\kappa_S=|S|-2\big(|S|-r(S)\big)=2r(S)-|S|.$$

The hinge walls. For a set R of width one, Proposition 8.16 gives

$$\kappa_R+\kappa_{\mathcal{E}\setminus R}=\kappa_{\mathcal{E}}+2\sigma\,c(R)=0+2\cdot1\cdot1=2,$$

and both walls are integers at least 1, F being convergent; so $\kappa_R=\kappa_{\mathcal{E}\setminus R}=1$. By Proposition 21.3(iii) the list is $\mathcal{H}\langle\mathcal{A}\rangle$, the cell of the bunch $\mathcal{A}$ on $R\sqcup\{g\}$ substituted at the marker h of the cell of the room $\mathcal{H}$, the marks of $L=\mathcal{E}\setminus R$ left in place. One letter is active, so the cell is read through the one hinge value $\gamma^{\Psi}_{\mathcal{A}}$, and Theorem 34.17 applies with $q=1$, $2\sigma=2$, $\kappa_1=\kappa_R=1$ and the loads $a=0$, $b=1$. The core family $(\mathcal{H};0,2)$ carries the masses $\mathbf{1}_L$ and $\kappa_R=1$ at h, and the cell family $(\mathcal{A};0,2)$ the masses $\mathbf{1}_R$ and $2\sigma-\kappa_R=1$ at g: both have the masses $\mathbf{1}$, and both are convergent (Theorem 34.17(i),(iii)). The pinned family G has the tables $\mathcal{A}\setminus g$ at $(0,2-1)=(0,1)$ and $\mathcal{A}/g$ at $(0,1)$, at the masses $\mathbf{1}_R$. The Beta corner of the split is

$$\Gamma_{\begin{smallmatrix}2\\1\end{smallmatrix}}\begin{bmatrix}\kappa_1,\ 2\sigma-\kappa_1\\ 2\sigma\end{bmatrix}=\Gamma_{\begin{smallmatrix}2\\1\end{smallmatrix}}\begin{bmatrix}1,\ 1\\ 2\end{bmatrix}=\frac{\Gamma(1)\,\Gamma(1)}{\Gamma(2)}=1.$$

So Theorem 34.17(ii),(iii) give $P^{\mathrm{mot}}_F=P^{\mathrm{mot}}_{(\mathcal{H};0,2)}P^{\mathrm{mot}}_G$ and $P^{\mathrm{mot}}_{(\mathcal{A};0,2)}=1\cdot P^{\mathrm{mot}}_G$, that is

$$P^{\mathrm{mot}}_F=P^{\mathrm{mot}}_{(\mathcal{H};0,2)}\,P^{\mathrm{mot}}_{(\mathcal{A};0,2)},$$

both at the masses $\mathbf{1}$: the split costs no factor.

(ii) *The nodes.* Each of the two families of (i) is again a convergent family of one list at $(0,2)$ with the masses $\mathbf{1}$, so (i) applies to it: it has an even number $2r_v$ of marks, and every further split costs no factor. A node made by a split has at least three marks, two of one side and its marker, and an even number of them, hence at least four; so no node on two or three marks occurs. A node at which the splitting stops has no set of width one with two marks on each side, and it is connected, since $\kappa_S+\kappa_{\mathcal{E}_v\setminus S}=2c(S)$ with both walls at least 1 gives $c(S)\geq1$ (Proposition 8.16, Definition 8.1); so it is prime (Theorem 23.16), as Corollary 34.18(b) says of the nodes on at least four marks. By induction on the number of marks,

$$P^{\mathrm{mot}}_F=\prod_v P^{\mathrm{mot}}_{F_v},\qquad F_v=(\mathcal{H}_v;0,2)\text{ at the masses }\mathbf{1},\qquad \mathrm{C}\big(P^{\mathrm{mot}}_F\big)\subseteq\prod_v\mathrm{C}\big(P^{\mathrm{mot}}_{F_v}\big)$$

(Lemma 34.6(iii)): the rational constant of Corollary 34.18(b) is 1, and every marker carries the mass 1. By Corollary 34.8 the same holds at $(2,0)$, whose masses $2\sigma\mathbf{1}-\mathbf{1}$ are again $\mathbf{1}$.

(iii) *The list* T_6. Every set of at most three marks other than $\{1,2,3\}$ lies in a basis, $r(\{1,2,3\})=2$, and every set of at least four marks contains a basis; $n=6=2r$, so T_6 at $(0,2)$ with the masses $\mathbf{1}$ is on its balance wall. By (i) its walls are $2r(S)-|S|$:

S	$\lvert S\rvert=1$	$\lvert S\rvert=2$	$\lvert S\rvert=3,\ S\neq\{1,2,3\}$	$S=\{1,2,3\}$	$\lvert S\rvert=4$	$\lvert S\rvert=5$
$r(S)$	1	2	3	2	3	3
κ_S	1	2	3	1	2	1

all at least 1: $(\mathrm{T}_6; 0, 2)$ is convergent. Its widths $c(S) = r(S) + r(\mathcal{E} \setminus S) - 3$ (Definition 7.12) are 1 at one mark, 2 at two marks, 3 at a triple other than $\{1, 2, 3\}$ and $\{4, 5, 6\}$ and 2 at these two: the sets with two marks on each side have widths two and three, and T_6 is connected and prime (Theorem 23.16). The mark 6 is neither a loop nor a coloop, so $\mathcal{T}$ is a cell, with the hinge minors

$$\mathcal{T} \setminus g: \text{ the nine triples of } \{1, \dots, 5\} \text{ other than } \{1, 2, 3\}, \qquad \mathcal{T}/g: \text{ the ten pairs of } \{1, \dots, 5\},$$

of the ranks 3 and 2 (Definition 7.3).

The list D_{10}. By Lemma 21.12 it is a list on ten marks of rank $3 + 3 - 1 = 5$, with the $9 \cdot 10 + 10 \cdot 9 = 180$ bases $X \sqcup Y$, $X \in \mathcal{T} \setminus g$ and $Y \in \mathcal{T}'/g$ or $X \in \mathcal{T}/g$ and $Y \in \mathcal{T}' \setminus g$, and $S = \{1', \dots, 5'\}$ is a bunch of width one with the cell of the bunch $\mathcal{T}'$ and the cell of the room $\mathcal{T}$. At $(0, 2)$ with the masses $\mathbf{1}$ it is on its balance wall, $10 = 2 \cdot 5$, and its hinge walls are (Lemma 21.12)

$$\kappa_S = m_S - 2\left(|S| - r_{\mathcal{T}'}\right) = 5 - 2\,(5 - 3) = 1, \qquad \kappa_{\mathcal{E}\setminus S} = 5 - 2\,(5 - 3) = 1,$$

adding to $2\sigma = 2$. One letter is active, so by Theorem 19.9(iii) every proper wall of D_{10} is positive exactly when both cell families are, $(\mathcal{T}'; 0, 2)$ and $(\mathcal{T}; 0, 2)$ at the masses $\mathbf{1}$, the hinge carrying $2\sigma - \kappa = 1$: two copies of $(\mathrm{T}_6; 0, 2)$ at $\mathbf{1}$, whose walls are displayed above. So $(\mathrm{D}_{10}; 0, 2)$ is convergent; the receipt finds the least of its 1022 proper walls to be 1.

The motivic period. The split at S gives the nodes $\mathcal{T}'$ and $\mathcal{T}$, copies of T_6 with the marker in place of the mark 6, both prime; by (ii), and Lemma 34.7 for the renaming of the marks,

$$P^{\mathrm{mot}}_{(\mathrm{D}_{10};0,2)} = \left(P^{\mathrm{mot}}_{(\mathrm{T}_6;0,2)}\right)^2, \qquad \mathrm{C}\big(P^{\mathrm{mot}}_{(\mathrm{D}_{10};0,2)}\big) \subseteq \mathrm{C}\big(P^{\mathrm{mot}}_{(\mathrm{T}_6;0,2)}\big) \cdot \mathrm{C}\big(P^{\mathrm{mot}}_{(\mathrm{T}_6;0,2)}\big),$$

all at the masses $\mathbf{1}$, with the Beta corner 1 and no other factor.

The set S *at the centre.* At $(1, 1)$ with the masses $\mathbf{1}$ the walls are the widths (Proposition 8.21(ii)), all positive, D_{10} being connected by (ii); so Theorem 28.25 applies. With both letters active and $|S| = 5$, S is pinned exactly when $\mathbf{E}_{\mathrm{D}_{10}|S} = \mathbf{E}_{\mathrm{D}_{10}/(\mathcal{E}\setminus S)}$, and these hinge minors are $\mathcal{T}' \setminus g$ and $\mathcal{T}'/g$ (Theorem 19.4), with 9 and 10 bases. At the gauge $\mathbf{1}$ the even letter of a list is the square of its number of bases, so the two even letters take the values 81 and 100 there and differ: at the centre S is not pinned, it does not split off, and its law is carried by no point. At $(0, 2)$ one letter is active, so S is pinned (Theorem 28.25(ii)) and splits off, with the Beta corner 1, as above.

Answer. At $(0, 2)$ with the masses $\mathbf{1}$, $|\mathcal{E}| = 2r$ and $\kappa_S = 2r(S) - |S|$; at a set of width one the two hinge walls add to 2 and are 1, the cell families keep the masses $\mathbf{1}$, and the Beta corner is $\Gamma_{\begin{smallmatrix}2\\1\end{smallmatrix}}\begin{bmatrix}1, & 1\\ & 2\end{bmatrix} = 1$. Every node of the splitting is prime, and $P^{\mathrm{mot}}_F = \prod_v P^{\mathrm{mot}}_{F_v}$ with every $F_v = (\mathcal{H}_v; 0, 2)$ at the masses $\mathbf{1}$. For $\mathrm{D}_{10} = \mathcal{T} \oplus_g \mathcal{T}'$, a list of rank five on ten marks with 180 bases,

$$P^{\mathrm{mot}}_{(\mathrm{D}_{10};0,2)} = \left(P^{\mathrm{mot}}_{(\mathrm{T}_6;0,2)}\right)^2 \quad \text{at the masses } \mathbf{1};$$

the set $\{1', \dots, 5'\}$ splits off at $(0, 2)$ and does not split off at the centre, where its hinge minors have the even letters 81 and 100 at the gauge $\mathbf{1}$. □

Chapter 54

Exercises on rays: the small centres

The exercises of this chapter read the list $\binom{[3]}{1}$ along its rays. Its centre ray is read four ways. A certificate proves its law at every strength, the low-end relation fixes the scale, and positivity with the native value of the direction brackets the value $\ell = P_{\binom{[3]}{1}}(\mathbf{1}; 1, 1)$ to 10^{-7}. The box of its walls gives a spanning set of two insertions, the one-step matrix, a certificate supported on the stems and the law, with no closing computed, and shows why the closing relations alone do not give the law. The gauge end gives the values and their slopes to a hundred digits with no datum from the low end, and returns the low-end coefficients. The torus through the native gauge carries a second solution of the law; the torus value, the values and the torus read backwards are tied by an explicit connection, which reads the mean of $\log|K|$ on the torus and writes ℓ as three times a Trailmoment of index two of the lattice inputs of step three. A lean of three marks and the balanced directions of small size have their values in $\mathbb{Q} + \mathbb{Q}\ell$, read as values of insertions along the centre ray and reduced in its boxes. Every number displayed is exact unless it is labelled as a rendering; the receipts that recompute them are the scripts named in the solutions.

54.1 The centre ray, bracketed

Exercise 54.1 (The centre ray of $\binom{[3]}{1}$, bracketed)**.** Let F be the list $\binom{[3]}{1}$: the marks $\mathcal{E} = \{1, 2, 3\}$, the bases $\{1\}, \{2\}, \{3\}$ and unit weights, so that its letters are

$$K = \alpha_1 + \alpha_2 + \alpha_3, \qquad \Psi = \alpha_1\alpha_2 + \alpha_1\alpha_3 + \alpha_2\alpha_3.$$

Let $P(k) = P_F(k\mathbf{1}; k, k)$ be the values of its centre ray at the strength 1, and $\ell = P(1)$.

(i) From the closings of the ray find a candidate recurrence of the values, and prove it by a certificate.

(ii) Show that it holds at every k with $\operatorname{Re} k > 0$, and read its low-end relation.

(iii) Find a rational q with $0 < \ell - q < 10^{-6}$, and prove both inequalities.

Exact computation may be done by machine; floating point, quadrature and integer-relation searches serve only as checks.

Solution. Receipt: `ex18_centre_bracket.py`. Throughout, e_1, e_2, e_3 are the elementary symmetric polynomials of $\alpha_1, \alpha_2, \alpha_3$, so that $K = e_1$ and $\Psi = e_2$, and $D_e = \alpha_e\,\partial/\partial\alpha_e$, which is ∂_{y_e} in the coordinates $y_e = \log\alpha_e$.

Step 1: the ray. The list has rank 1. For a nonempty proper S, $r(S) = 1$ and $r^*(S) = |S| + r(\mathcal{E} \setminus S) - 1 = |S|$, so $d(S) = 0$, $d^*(S) = |S| - 1$ and the width is $c(S) = 1$ (Definition 7.12).

The family is connected at the strength 1, and its centre ray (Definition 38.13) has the origin 0, the direction $(\mathbf{1};1,1)$ and the walls $\kappa_{1,S}=c(S)=1$ for every nonempty proper S. On the chart $\alpha_3=1$ of the mark $e_0=3$, with $\alpha_1=e^{y_1}$, $\alpha_2=e^{y_2}$ and $dy=d\alpha_1\,d\alpha_2/(\alpha_1\alpha_2)$,

$$f=\frac{\alpha^{\mathbf{1}}}{K\Psi}=\frac{e_3}{e_1e_2},\qquad P(k)=\int_{\mathbb{R}^2}f^k\,dy,\qquad \ell=\int_0^\infty\!\!\int_0^\infty\frac{d\alpha_1\,d\alpha_2}{(1+\alpha_1+\alpha_2)(\alpha_1+\alpha_2+\alpha_1\alpha_2)}.$$

The measure is dy: with $d\alpha_1\,d\alpha_2$ in its place the integrand is of the order of $1/(\alpha_1+\alpha_2)$ at infinity and the integral diverges. The volume of the direction (Proposition 39.34) is $V_1=\sum_\pi\prod_{l=2}^3\kappa_{1,U_l}^{-1}=3!\cdot1=6$.

Step 2: the stride. (a) Both sides of

$$e_1e_2-9e_3=\alpha_1(\alpha_2-\alpha_3)^2+\alpha_2(\alpha_3-\alpha_1)^2+\alpha_3(\alpha_1-\alpha_2)^2$$

equal $\sum_{i\neq j}\alpha_i^2\alpha_j-6e_3$, the left one because $e_1e_2=\sum_{i\neq j}\alpha_i^2\alpha_j+3e_3$. So $0<f\le\frac19$ on the orthant, with equality exactly on the diagonal, which on the chart is the point $y=0$: the native gauge of the direction is $\alpha^\star=\mathbf{1}$ and $f(\alpha^\star)=\frac19$ (Theorem 38.14(i)). Every $P(k)$, $k>0$, converges and is positive, and since $f<\frac19$ off one point,

$$P(k+1)=\int f\cdot f^k\,dy<\tfrac19\,P(k)\qquad(k>0).$$

(b) Order the coordinates, $\alpha_{(1)}\ge\alpha_{(2)}\ge\alpha_{(3)}$. Then $\alpha_{(1)}\le e_1\le3\alpha_{(1)}$, $\alpha_{(1)}\alpha_{(2)}\le e_2\le3\alpha_{(1)}\alpha_{(2)}$ and $e_3=\alpha_{(1)}\alpha_{(2)}\alpha_{(3)}$, so $\frac19\,\alpha_{(3)}/\alpha_{(1)}\le f\le\alpha_{(3)}/\alpha_{(1)}$. On the chart $\alpha_{(3)}/\alpha_{(1)}=e^{-\varphi(y)}$ with $\varphi(y)=\max(y_1,y_2,0)-\min(y_1,y_2,0)$. The lines $y_1=y_2$, $y_1=0$, $y_2=0$ cut the plane into six cones, one for each order of the entries of $(y_1,y_2,0)$, and on each φ is the largest entry less the smallest; for real $k>0$

$$\int_{y_1\ge y_2\ge0}e^{-ky_1}dy=\int_{y_1\ge0\ge y_2}e^{-k(y_1-y_2)}dy=\int_{0\ge y_1\ge y_2}e^{ky_2}dy=\frac{1}{k^2},$$

and the three cones with y_1 and y_2 exchanged give the same, so $\int e^{-k\varphi}dy=6/k^2$ and

$$\frac{6\cdot9^{-k}}{k^2}\le P(k)\le\frac{6}{k^2}\qquad(k>0).$$

The six cones are the six orders π of Proposition 39.34, each contributing $\prod_l\kappa_{1,U_l}^{-1}=1$. On $[k_1,\infty)$ the integrands f^k are dominated by f^{k_1}, as $0<f<1$, so P is continuous on $(0,\infty)$.

Step 3: the candidate recurrence. Here $f^{-1}=e_1e_2/e_3=(\alpha_1+\alpha_2+\alpha_3)(\alpha_1^{-1}+\alpha_2^{-1}+\alpha_3^{-1})$, a Laurent polynomial, and the closings of 1 (Definition 39.30) are its constant terms,

$$x_j=\mathsf{C}_j(1)=\mathrm{CT}\left(f^{-j}\right)=\sum_{a_1+a_2+a_3=j}\Big(\frac{j!}{a_1!\,a_2!\,a_3!}\Big)^2,$$

$$(x_j)_{j\ge0}=1,\ 3,\ 15,\ 93,\ 639,\ 4653,\ 35169,\ 272835,\ 2157759,\ \ldots,$$

since the constant term pairs the monomial α^a of $(\sum_e\alpha_e)^j$ with the monomial α^{-a} of $(\sum_e\alpha_e^{-1})^j$, both with the coefficient $j!/(a_1!a_2!a_3!)$. Exact linear algebra with the ansatz $\sum_{i=0}^2p_i'(j)\,x_{j+i}=0$, $\deg p_i'\le2$, on $x_0,\ldots,x_{15}$ (14 equations in 9 unknowns) has a space of solutions of dimension one,

$$(j+2)^2x_{j+2}-(10j^2+30j+23)\,x_{j+1}+9(j+1)^2x_j=0.$$

By Corollary 39.36 a law $\sum_i p_i(k)\,\mathrm{Sh}^i[1]=0$ gives $\sum_i p_i(-j)\,x_{j-i}=0$; read back, $p_i(k)=p'_{2-i}(-k-2)$ is the candidate

$$k^2P(k)-(10k^2+10k+3)\,P(k+1)+9(k+1)^2\,P(k+2)=0. \tag{L}$$

At this point (L) is a candidate: sixteen closings do not prove their own recurrence, and Corollary 39.36 runs from a law to its closings.

Step 4: the certificate. The defects of the direction (Definition 38.1, Lemma 38.2(ii)) are

$$c_e=D_e\log f=1-R_e-R_e^*,\qquad R_e=\frac{\alpha_e}{e_1},\qquad R_e^*=\frac{\alpha_e(e_1-\alpha_e)}{e_2},$$

the occupations of e under the basis law and under the cobasis law; $\sum_e R_e=1$ and $\sum_e R_e^*=2$, so $\sum_e c_e=0$. The origin is 0, so its defects vanish, and a certificate of (L) (Proposition 38.5(i): an explicit element of the relation space $\mathcal{L}$ of Definition 38.4 whose image is the recurrence) is a choice of insertions g_1,g_2,g_3 with

$$k^2-(10k^2+10k+3)\,f+9(k+1)^2f^2=\sum_{e=1}^{3}\big(k\,c_e+D_e\big)g_e. \tag{C}$$

The ansatz: $g_e=N_e/(e_1^2e_2)$, N_e homogeneous of degree 4 with coefficients in $\mathbb{Q}+\mathbb{Q}k$, N_1 symmetric in α_2,α_3 and g_e the image of g_1 under the exchange of the marks 1 and e. Multiplied by $e_1^3e_2^2$, (C) is a polynomial identity of degree 7 in α and 2 in k, linear in the 18 coefficients of N_1: 99 equations of rank 10. One solution is

$$g_1=-\frac{\alpha_1^2\big(k\,\alpha_1(\alpha_2+\alpha_3)+(2+3k)(\alpha_2^2+\alpha_3^2)-(1-k)\,\alpha_2\alpha_3\big)}{e_1^2e_2}, \tag{G}$$

and within the ansatz the others differ from it by one insertion h added at every mark, h with a symmetric numerator, an 8-dimensional space; such an h contributes $k\,h\sum_e c_e+\sum_e D_eh=0$, by Euler's identity for h of degree 0. Each g_e is a polynomial over $K^2\Psi$, homogeneous of degree 0, so a regular function on X_F: an insertion (Definition 38.1).

Verification. Write $g_e=g_e^{(0)}+k\,g_e^{(1)}$, with $e_1^2e_2\,g_1^{(0)}=-\alpha_1^2(2\alpha_2^2-\alpha_2\alpha_3+2\alpha_3^2)$ and $e_1^2e_2\,g_1^{(1)}=-\alpha_1^2(\alpha_1\alpha_2+\alpha_1\alpha_3+3\alpha_2^2+\alpha_2\alpha_3+3\alpha_3^2)$. The powers of k split (C) into

$$\sum_e c_eg_e^{(1)}=1-10f+9f^2,\qquad \sum_e\big(D_eg_e^{(1)}+c_eg_e^{(0)}\big)=-10f+18f^2,\qquad \sum_e D_eg_e^{(0)}=-3f+9f^2.$$

Times $e_1^3e_2^2$ every sum over the marks is a symmetric polynomial of degree 7, and in the basis of the products of e_1,e_2,e_3 exact expansion gives

$$\textstyle\sum_e e_1^3e_2^2\,c_eg_e^{(1)}=e_1^3e_2^2-10\,e_1^2e_2e_3+9\,e_1e_3^2,\qquad \sum_e e_1^3e_2^2\,D_eg_e^{(0)}=-3\,e_1^2e_2e_3+9\,e_1e_3^2,$$
$$\textstyle\sum_e e_1^3e_2^2\,D_eg_e^{(1)}=-2\,e_1e_2^3-3\,e_1^2e_2e_3+9\,e_1e_3^2,\qquad \sum_e e_1^3e_2^2\,c_eg_e^{(0)}=2\,e_1e_2^3-7\,e_1^2e_2e_3+9\,e_1e_3^2,$$

which, with $e_1^3e_2^2f=e_1^2e_2e_3$ and $e_1^3e_2^2f^2=e_1e_3^2$, are the three right sides times $e_1^3e_2^2$. So (C) holds identically in α and k: $\sum_i p_i(k)f^i\in\mathcal{L}$, with $(p_0,p_1,p_2)=\big(k^2,\,-(10k^2+10k+3),\,9(k+1)^2\big)$. To test another certificate on one point: at $\alpha=(1,2,4)$ and $k=\frac{1}{3}$, $f=\frac{4}{49}$, the left side of (C) is $-\frac{2809}{7203}$, and (G) gives $(g_1,g_2,g_3)=\big(-\frac{85}{1029},-\frac{310}{1029},-\frac{424}{1029}\big)$; agreement at a point is a test, the identity above is the proof.

Step 5: the recurrence at every strength. The terms of g_e are the insertions $\alpha^v K^{-2}\Psi^{-1}$ for the monomials α^v of N_e, with the data $(v;2,1)$ and the walls $\kappa_U = v_U - 2d(U) - d^*(U) = v_U - |U| + 1$. The monomials of N_1 are $\alpha_1^3\alpha_2$, $\alpha_1^3\alpha_3$, $\alpha_1^2\alpha_2^2$, $\alpha_1^2\alpha_3^2$ and $\alpha_1^2\alpha_2\alpha_3$; each has two marks in its support, so $v_U \geq 1$ for every pair U, and every wall is at least 0 (the least is 0). With the walls $k\kappa_{1,U} = k$ of the ray, the condition of Proposition 38.5(i) holds at every k with $\operatorname{Re} k > 0$, where the values converge, and the certificate gives (L) there. The integration by parts behind it handles the mark $e_0 = 3$ on its own chart: by Euler's identity $D_3 = -D_1 - D_2$ on functions of degree 0, so $\sum_e D_e(g_e f^k) = \partial_{y_1}\big((g_1 - g_3)f^k\big) + \partial_{y_2}\big((g_2 - g_3)f^k\big)$; y_3 is not a coordinate of the chart. Corollary 39.38(i) gives the same as an identity of meromorphic functions of k, for the element (C) of $\mathcal{L}$.

Step 6: the native values; what positivity selects. The symbol of (L) (Corollary 38.7) is $\chi(\lambda) = 1 - 10\lambda + 9\lambda^2 = (1-\lambda)(1-9\lambda)$. By Theorem 38.17 every sign η, $\eta_3 = 1$, with $K(\eta) \neq 0$ is a native gauge of native value $K(\eta)^{-2}$, with the Hessian $2\big(\kappa_\eta(X_e, X_{e'})\big)_{e,e'\neq 3}$ of the indicators under $\mathbb{P}_\eta(\{e\}) = \eta_e/K(\eta)$: at $\eta = (1,1,1)$, $K(\eta) = 3$, the native value is $\frac{1}{9}$ and the Hessian is $2\left(\begin{smallmatrix} 2/9 & -1/9 \\ -1/9 & 2/9 \end{smallmatrix}\right)$, of determinant $\frac{4}{27}$; at $(-1,1,1)$, $(1,-1,1)$, $(-1,-1,1)$, $K(\eta) = \pm 1$, the native value is 1 and the determinant is -4 (at $(-1,1,1)$ the matrix is $2\left(\begin{smallmatrix} -2 & 1 \\ 1 & 0 \end{smallmatrix}\right)$). All four are nondegenerate, so Corollary 38.7 at $g = 1$ makes $\frac{1}{9}$ and 1 roots of χ; χ has degree 2, so they are all its roots. (The corollary runs from native values to roots; a root of a symbol need not be a native value.) The root other than $f(\alpha^\star) = \frac{1}{9}$ has the modulus $1 > \frac{1}{9}$, so Theorem 41.3(iii) applies: up to a constant factor the values are the only solution of (L) whose generating function has a radius of convergence of at least 9, and the low-end relation fixes the factor. The rational solutions of (L) grow like the native value 1 of the signs and the values decay like 9^{-k}, so a bracket from positivity shrinks by about $\frac{1}{9}$ per step of the strength.

Step 7: the low-end relation. By Step 2(b), $6 \cdot 9^{-k} \leq k^2 P(k) \leq 6$ for real $k > 0$, so $k^2 P(k) \to 6$ as $k \to 0^+$: the low-end coefficient L_0 is $V_1 = 6$ (Definition 39.37). Corollary 39.38(ii) applies to the element (C): $p_0 = k^2$ vanishes to the order $n - 1 = 2$ at 0, $[k^2]p_0 = 1$, $p_1(0) = -3$, $p_2(0) = 9$, and

$$6 - 3\ell + 9P(2) = 0, \qquad P(2) = \frac{\ell - 2}{3}. \tag{S}$$

Directly: take (L) at real $k \in (0,1)$ and let $k \to 0^+$; $k^2P(k) \to 6$, $P(k+1) \to \ell$ and $P(k+2) \to P(2)$ by the continuity of Step 2, while $10k^2 + 10k + 3 \to 3$ and $9(k+1)^2 \to 9$.

A solution that looks right goes wrong here. Reading (L) at $k = 0$ as $0 \cdot P(0) - 3P(1) + 9P(2) = 0$ treats $0 \cdot P(0)$ as 0; but $P(0) = \int dy = \infty$, and the product $k^2P(k)$ tends to $V_1 = 6$. The misreading gives $P(2) = \ell/3$, which Step 2(a) refutes at once: $P(2) < \frac{1}{9}P(1)$ would say $\frac{\ell}{3} < \frac{\ell}{9}$. Every $P(K)$ would then be ℓ times a positive rational, positivity would fix no digit of ℓ, and the bracket of Step 9 would be empty. Passing the limit under the integral, $k^2 f^k \to 0$ pointwise, fails for the same reason: there is no integrable majorant, $\int dy$ being infinite.

Step 8: the rational solutions and their signs. For integers $k \geq 1$, $9(k+1)^2 \neq 0$, so (L) gives $P(k+2)$ from $P(k)$ and $P(k+1)$. Let c and r be the solutions with $c(1) = 1$, $c(2) = \frac{1}{3}$ and $r(1) = 0$, $r(2) = -\frac{2}{3}$. From $P(1) = \ell$, (S) and induction,

$$P(K) = c(K)\,\ell + r(K) \qquad (K \geq 1).$$

Signs at every K. Put $x'_j = 9^j c(j+1)$. Then (L) at $k = j+1$, times 9^{j+1}, reads

$$(j+2)^2 x'_{j+2} = (10j^2 + 30j + 23)\,x'_{j+1} - 9(j+1)^2 x'_j, \qquad x'_0 = 1,\ x'_1 = 3.$$

If $x'_{j+1} \geq 3x'_j > 0$, then $(j+2)^2 x'_{j+2} \geq \big(10j^2 + 30j + 23 - 3(j+1)^2\big)x'_{j+1} = (7j^2 + 24j + 20)\,x'_{j+1} \geq 3(j+2)^2 x'_{j+1}$, because $7j^2 + 24j + 20 - 3(j+2)^2 = 4(j+1)(j+2) \geq 0$. So $x'_{j+1} \geq 3x'_j > 0$ for

every j, $x'_j \geq 3^j$, and

$$c(K) \geq 3^{1-K} > 0, \qquad 9c(K) \geq 3c(K-1) > c(K-1) \qquad (K \geq 2).$$

The closings satisfy the same recurrence with the same first two terms (Corollary 39.38(i) for the element (C)), so $x'_j = x_j$ and $c(K) = 9^{1-K} x_{K-1}$ at every K; the signs do not use this. In exact arithmetic:

K	$c(K)$	$r(K)$	$a_K = -r(K)/c(K)$
1	1	0	0
2	1/3	−2/3	2
3	5/27	−23/54	23/10
4	31/243	−145/486	145/62
5	71/729	−1331/5832	1331/568
6	517/6561	−242353/1312200	242353/103400
7	11723/177147	−5495507/35429400	5495507/2344600
8	10105/177147	−46422941/347208120	46422941/19805800
9	26639/531441	−2447622221/20832487200	2447622221/1044248800
10	5773279/129140163	−530455590781/5062294389600	530455590781/226312536800

The frame of c and r (Proposition 38.11, $h = 2$) satisfies $C_{k+1} = \frac{p_0(k)}{p_2(k)} C_k = \frac{k^2}{9(k+1)^2} C_k$ with $C_1 = c(1)r(2) - c(2)r(1) = -\frac{2}{3}$, so

$$c(k)\, r(k+1) - c(k+1)\, r(k) = -\frac{2}{3} \cdot \frac{9^{1-k}}{k^2} \qquad (k \geq 1).$$

Step 9: the bracket and the answer. (a) *Below, by positivity.* $P(K) = c(K)\ell + r(K) > 0$ and $c(K) > 0$ give $\ell > a_K = -r(K)/c(K)$. (b) *Above, by the native value.* $P(K) < \frac{1}{9} P(K-1)$ (Step 2(a)) is $\big(9c(K) - c(K-1)\big)\ell < r(K-1) - 9r(K)$, and $9c(K) - c(K-1) > 0$ (Step 8), so

$$\ell < b_K = \frac{r(K-1) - 9\, r(K)}{9\, c(K) - c(K-1)}.$$

At $K = 2$ this is the first bracket: $P(2) = \frac{\ell - 2}{3} > 0$ gives $\ell > 2$, and $P(2) < \frac{1}{9} P(1)$ gives $\ell < 3$. (c) *The width.* With the frame at $k = K-1$ and $c(K) = 9^{1-K} x_{K-1}$,

$$\begin{aligned} b_K - a_K &= \frac{r(K-1)\, c(K) - r(K)\, c(K-1)}{c(K)\big(9c(K) - c(K-1)\big)} = \frac{2 \cdot 9^{2-K}}{3(K-1)^2\, c(K)\big(9c(K) - c(K-1)\big)} \\ &= \frac{2 \cdot 9^{K-1}}{3(K-1)^2\, x_{K-1}(x_{K-1} - x_{K-2})}, \end{aligned}$$

which the bounds of Step 8 make at most $1/(K-1)^2$: the brackets close on one number. In exact arithmetic, with the width also as a rendering:

K	b_K	$b_K - a_K$	rendering
2	3	1	
3	19/8	3/40	$7.5 \cdot 10^{-2}$
4	61/26	3/403	$7.44 \cdot 10^{-3}$
5	3413/1456	81/103376	$7.84 \cdot 10^{-4}$
6	104539/44600	243/2882275	$8.43 \cdot 10^{-5}$
7	149014/63575	2187/238492712	$9.17 \cdot 10^{-6}$
8	909876251/388187800	19683/19613188595	$1.0036 \cdot 10^{-6}$
9	6414407843/2736630400	6561/59511099776	$1.1025 \cdot 10^{-7}$
10	232184895407/99058909600	177147/14589151085627	$1.214 \cdot 10^{-8}$

At $K = 8$ the certified width exceeds 10^{-6}; at $K = 9$ it is $\frac{6561}{59511099776} < \frac{111}{10^9}$.

Answer. $q = a_9 = \dfrac{2447622221}{1044248800}$, with

$$\frac{2447622221}{1044248800} < \ell < \frac{6414407843}{2736630400}, \qquad b_9 - a_9 = \frac{6561}{59511099776} < 1.11 \cdot 10^{-7},$$

so $0 < \ell - q < 10^{-6}$.

What does not certify. The value a_8 is also a correct answer, but the bracket at $K = 8$ is too wide to show it; the upper bound at $K = 9$ does, $\ell - a_8 < b_9 - a_8 = \frac{19683}{22574408320} < 10^{-6}$. A rate of convergence is no bound, and neither is the last step: $a_9 - a_8$ is smaller than $\ell - a_8$, since $a_9 < \ell$. The bound $P(K) \le 9^{-K}\ell$ does not follow from $f \le \frac{1}{9}$ (it would need $\int dy < \infty$); iterating Step 2(a) gives $P(K) < 9^{1-K}P(1) = 9^{1-K}\ell$, that is $\big(c(K) - 9^{1-K}\big)\ell < -r(K)$ with $c(K) - 9^{1-K} = 9^{1-K}(x_{K-1} - 1) > 0$ for $K \ge 2$: a valid and cruder upper bound, which needs $K = 10$ to certify six digits. A sign of $c(K)$ or of $9c(K) - c(K-1)$ that is not proved can reverse an inequality: here Step 8 proves both at every K.

Check (floating point, not part of the solution). On the chart the integral over α_2 is elementary, $\int_0^\infty \frac{d\alpha_2}{(\alpha_2+A)(A\alpha_2+B)} = \frac{\log(A^2/B)}{A^2-B}$ with $A = 1 + \alpha_1$, $B = \alpha_1$, so

$$\ell = \int_0^\infty \frac{\log\big((1+x)^2/x\big)}{1+x+x^2}\,dx,$$

which renders as $2.343907238689458890601562288872277069095\ldots$; then $\ell - a_9$ and $b_9 - \ell$ render as $9.6062 \cdot 10^{-8}$ and $1.4186 \cdot 10^{-8}$. Exercise 54.3 computes ℓ to a hundred digits without quadrature. □

54.2 The centre ray by its box

Exercise 54.2 (The centre of $\binom{[3]}{1}$ by its box)**.** Let F, P and ℓ be as in Exercise 54.1. Read the centre ray of F by steps (1) to (4) and (6) of the procedure of Definition 41.8, with the box $\mathfrak{B}_2(1,1)$ (Definition 39.15) modulo the group G generated by the permutations of the marks and the Cremona: give its symbols, orbits and relations, the pivots and the free orbits, the spanning set at $\mathfrak{s} = 1$, the matrix $\mathbf{B}(k)$, a certificate supported on the stems, the law of [1], $\mathbf{B}(\infty)$ and the closings of the spanning set. Show that the closing relations alone do not give the law.

Solution. Receipt: `ex19_centre_box.py`. The elimination is small enough to run once over $\mathbb{Q}(k)$, so the evaluation at random strengths of step (2) of the procedure is not needed.

Step 1: walls and symmetries. The walls of the direction are $\kappa_{1,S} = 1$ and $V_1 = 6$ (Exercise 54.1, Step 1). Every permutation β of the marks carries the bases and keeps the masses **1** and

the exponents, and the Cremona is a symmetry because the masses are $\sigma\mathbf{1}$ and $s = t$ (Proposition 39.11(ii)). So $G = S_3 \times \{1, \mathrm{cr}\}$, of order 12, acting on the symbols by $(u; a, b) \mapsto (u \circ \beta^{-1}; a, b)$ and $(u; a, b) \mapsto (-u + (a+b)\mathbf{1}; b, a)$ (Proposition 39.11(iii)).

Step 2: the box. Both letters are active, so the box with one unit of each active letter at $\mathfrak{t} = 2$ is $\mathfrak{B} = \mathfrak{B}_2(1,1)$: the symbols $(u; a, b)$ with $a, b \in \{0, 1\}$, $u_{\mathcal{E}} = a + 2b$, and wall degree $\deg_\kappa = \max_U(-\kappa_U) \le 2$, where $\kappa_U = u_U - a\,d(U) - b\,d^*(U) = u_U - b(|U| - 1)$. It has 110 symbols, 19 at the level $(0,0)$, 27 at each of $(1,0)$ and $(0,1)$ and 37 at $(1,1)$. G keeps it, the Cremona exchanging the levels $(1,0)$ and $(0,1)$, and the symbols fall into 16 orbits:

orbit of	level	$\deg_\kappa$	size		orbit of	level	$\deg_\kappa$	size	
$\alpha_1^4/(\alpha_3 K\Psi)$	$(1,1)$	2	12	pivot	$\alpha_1^3/(\alpha_2\alpha_3 K)$	$(1,0),(0,1)$	2	6	pivot
$\alpha_1^4\alpha_2/(\alpha_3^2 K\Psi)$	$(1,1)$	2	6	pivot	$\alpha_1^2\alpha_2/(\alpha_3^2 K)$	$(1,0),(0,1)$	2	12	pivot
$\alpha_1^3/(K\Psi)$	$(1,1)$	1	6	pivot	$\alpha_1^3/(\alpha_3^2 K)$	$(1,0),(0,1)$	2	12	pivot
$\alpha_1^3\alpha_2/(\alpha_3 K\Psi)$	$(1,1)$	1	6	pivot	$\alpha_1\alpha_2/(\alpha_3 K)$	$(1,0),(0,1)$	1	6	pivot
$\alpha_1^2\alpha_2/(K\Psi)$	$(1,1)$	0	6	pivot	$\alpha_1^2/(\alpha_3 K)$	$(1,0),(0,1)$	1	12	pivot
$\alpha_1\alpha_2\alpha_3/(K\Psi)$	$(1,1)$	-1	1	free	α_1/K	$(1,0),(0,1)$	0	6	pivot
$\alpha_1^2/(\alpha_2\alpha_3)$	$(0,0)$	2	6	pivot	α_1/α_3	$(0,0)$	1	6	free
α_1^2/α_3^2	$(0,0)$	2	6	pivot	1	$(0,0)$	0	1	free

The stems are the 19 Laurent symbols. The relations (Definition 39.15(iv)) are the letter identities for K of the 46 symbols with $a = 0$, those for Ψ of the 46 symbols with $b = 0$, and the mark relations of the 19 stems at the 3 marks: 149 relations, which give 22 distinct combinations of orbit averages (Definition 39.20(i)), of rank 13 over $\mathbb{Q}(k)$. With the ranking of Definition 39.20(ii) (positive levels above the Laurent orbits, then the total level, then the wall degree), the elimination makes the 13 orbits marked in the table pivots; the free orbits are those of $f = \alpha_1\alpha_2\alpha_3/(K\Psi)$, of α_1/α_3 and of 1.

Step 3: the spanning set and the matrix. The free Laurent orbits of wall degree at most $\mathfrak{s} = 1$ give the spanning set $\mathbf{b} = (1, b_1)$, with $b_1 = \frac{1}{6}\sum_{i\ne j}\alpha_i/\alpha_j$, the average of the orbit of α_1/α_3 (Definition 39.20(iii)). The first target is reduced already: $f^{-1} = (\sum_e \alpha_e)(\sum_e \alpha_e^{-1}) = 3 + 6b_1$ identically. The second, $f^{-1}b_1$, has 19 monomials, and its reduction is a combination of 1 and b_1. So the box is accepted at $\mathfrak{s} = 1$, with

$$\mathbf{B}(k) = \begin{pmatrix} 3 & 6 \\ \dfrac{2(k-1)}{k-2} & \dfrac{(k-1)(7k-11)}{(k-2)^2} \end{pmatrix},$$

and by Theorem 39.21(i) and (iii) $[f^{-1}b_i] = \sum_l \mathbf{B}_{il}(k)[b_l]$ in the module, and $\langle b_i\rangle_{k-1} = \sum_l \mathbf{B}_{il}(k)\langle b_l\rangle_k$ as meromorphic functions of k.

Step 4: the certificate. Theorem 39.21(ii) provides combinations G_e of stems with $f^{-1}b_1 - \mathbf{B}_{21} - \mathbf{B}_{22}\,b_1 = \sum_e \big(k\,c_e + D_e\big)G_e$, c_e and D_e as in Exercise 54.1. With G_1 a combination of stems symmetric under the exchange of the marks 2 and 3 and G_e its image under the exchange of 1 and e, the identity is linear in 11 unknowns, 37 equations, with a family of solutions of dimension 6; one of them is

$$G_1 = \frac{\alpha_2^2+\alpha_3^2}{6(k-2)\,\alpha_1^2} + \frac{(5k^2-6k-4)\,\alpha_2\alpha_3}{6(k+1)(k-2)^2\,\alpha_1^2} + \frac{3k-4}{6(k+1)(k-2)^2}\Big(\frac{\alpha_3^2}{\alpha_1\alpha_2}+\frac{\alpha_2^2}{\alpha_1\alpha_3}\Big) + \frac{5k-9}{6(k-2)^2}\,\frac{\alpha_2+\alpha_3}{\alpha_1} + \frac{3k-4}{6(k+1)(k-2)}\Big(\frac{\alpha_3^2}{\alpha_2^2}+\frac{\alpha_2^2}{\alpha_3^2}\Big),$$

whose terms are stems, of wall degree 2, 2, 2, 1 and 2. The identity holds as one of rational functions in α and k (exact expansion); at $\alpha = (1, 2, 4)$, $k = \frac{1}{3}$, both sides are $\frac{11903}{800}$. Its coefficients have poles at $k = 2$ and $k = -1$, and by Theorem 39.21(iii) it integrates term by term at every real $k > 2$.

Step 5: the law. By Proposition 39.6 the rows are $w_0 = (1, 0)$, $w_1(k) = w_0\mathbf{B}(k) = (3, 6)$ and

$$w_2(k) = w_1(k-1)\,\mathbf{B}(k) = \Big(\frac{3(7k-10)}{k-2},\ \frac{6(10k^2-30k+23)}{(k-2)^2}\Big),$$

and their first dependence is $q_0w_0 + q_1w_1 + q_2w_2 = 0$ with $(q_0, q_1, q_2) = \big(9(k-1)^2,\ -(10k^2-30k+23),\ (k-2)^2\big)$. Then $p_j(k) = q_{2-j}(k+2)$ gives $\big(k^2,\ -(10k^2+10k+3),\ 9(k+1)^2\big)$: the recurrence (L) of Exercise 54.1, now with no closing computed, and with a certificate assembled from those of the rows (Theorem 39.21(iv)). As a check of Proposition 39.6(iv), $\det\mathbf{B}(k) = 9(k-1)^2/(k-2)^2$ and $\det[w_0; w_1] = 6$, so $q_0 \cdot 6 = q_2 \cdot 6 \cdot \det\mathbf{B}(k)$.

The spanning set is independent: at the native gauges $(1, 1, 1)$ and $(-1, 1, 1)$ (Exercise 54.1, Step 6) the vectors of values $\beta_c = (1, b_1(\alpha_c))$ are $(1, 1)$ and $(1, -\frac{1}{3})$, which span $\mathbb{C}^2$, so by Proposition 39.42(i) $1, b_1$ are masters of the submodule $\mathfrak{N}$ they span and $\mathbf{B} = \mathbf{B_b}$. By Proposition 39.6(ii) the order 2 is then the dimension of the cyclic submodule of [1], which is $\mathfrak{N}$, and (L) is the law of [1]. Finally

$$\mathbf{B}(\infty) = \begin{pmatrix} 3 & 6 \\ 2 & 7 \end{pmatrix}, \qquad \mathbf{B}(\infty)\begin{pmatrix} 1 \\ 1 \end{pmatrix} = 9\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \qquad \mathbf{B}(\infty)\begin{pmatrix} 1 \\ -\frac{1}{3} \end{pmatrix} = \begin{pmatrix} 1 \\ -\frac{1}{3} \end{pmatrix},$$

the reciprocals of the native values $\frac{1}{9}$ and 1, with the vectors β_c as eigenvectors (Proposition 39.42(ii)).

Step 6: checks. The closings of the spanning set are $\mathsf{C}_j(1) = x_j$ and, by the first row, $\mathsf{C}_j(b_1) = \frac{1}{6}(x_{j+1} - 3x_j) = 0, 1, 8, 60, 456, 3535, 27888, \ldots$; they satisfy $\mathsf{C}_{j+1}(\mathbf{b}) = \mathbf{B}(-j)\,\mathsf{C}_j(\mathbf{b})$ (Theorem 39.33) for $0 \le j < 12$. The low-end relation of (L) returns $V_1 = 6$ (Exercise 54.1, Step 7).

Step 7: the closing relations alone. The closing relations $(k\,c_e + D_e)(\alpha^w f^{-1})$ involve Laurent insertions only (Proposition 39.19). Let $\omega = e^{2\pi i/3}$ and $z = (1, \omega, \omega^2)$. Then $K(z) = 1+\omega+\omega^2 = 0$ and $\Psi(z) = \omega+\omega^2+\omega^3 = 0$, so $f^{-1} = K\Psi/e_3$ and every $D_ef^{-1} = (\Psi D_eK + KD_e\Psi)/e_3 - f^{-1}$ vanish at z: z is a singular point of the zero set of f^{-1} on the torus. By Proposition 39.19(i) the evaluation at z vanishes on every closing relation, and by (ii) it takes the value $p_2(k-2) = 9(k-1)^2 \ne 0$ on the element $\sum_{i=0}^{2} p_{2-i}(k-2)f^{-i}$ of $\mathcal{L}$ that the law gives: no combination of closing relations gives the law. Concretely, at the strength 9 the elimination of the closing relations of the Laurent monomials of wall degree at most $R-1$, on the invariant Laurent combinations of wall degree at most R, leaves three free orbits, 1, b_1 and $b_2 = \frac{1}{6}\sum_{i\ne j}\alpha_i^2/\alpha_j^2$, for every R from 3 to 7; the law at $k = 7$, read at the strength 9 as $49f^{-2} - 563f^{-1} + 576$, reduces for each such R to

$$504 + 248\,b_1 - 392\,b_2 \ne 0,$$

and at z, where $b_1(z) = b_2(z) = -\frac{1}{2}$, this is $576 = 9(k+1)^2$. At $k = 10$ and $k = \frac{23}{3}$ the reductions are $880 + \frac{946}{3}b_1 - \frac{2200}{3}b_2$ and $\frac{8671}{15} + \frac{1313}{5}b_1 - \frac{6877}{15}b_2$, with the values 1089 and 676 at z, again $9(k+1)^2$. The point z lies off X_F; the box supplies the relations that the closing relations lack through its units of the letters, by the letter identities and the mark relations of the occupations.

Answer. The box $\mathfrak{B}_2(1, 1)$ modulo G has 110 symbols in 16 orbits and 149 relations of rank 13 modulo G; it is accepted at $\mathfrak{s} = 1$ with the masters 1 and $b_1 = \frac{1}{6}\sum_{i\ne j}\alpha_i/\alpha_j$ and the matrix $\mathbf{B_b}(k)$ above, with the certificate G_1 on the stems; the law of [1] is (L), and $\mathbf{B_b}(\infty)$ has the eigenvalues 9 and 1. The closing relations alone leave the evaluation at $(1, \omega, \omega^2)$, on which the law takes the value $9(k+1)^2$. □

54.3 The centre ray from its gauge end

Exercise 54.3 (The centre of $\binom{[3]}{1}$ from its gauge end)**.** Let F, P, ℓ and the law (L) be as in Exercise 54.1, and let μ_f be the stride's law of the centre ray (Definition 40.1), with the density ϱ_f.

(i) Write the density operator of (L), its exponents at $f(\alpha^\star) = \frac{1}{9}$, and the germs there that extend by zero.

(ii) Find $\varrho_f(\frac{1}{9})$ and the Taylor coefficients of the germ of ϱ_f at $\frac{1}{9}$.

(iii) Read $P(1)$, $P'(1)$ and $P''(1)$ from the gauge end (Theorem 40.6) to sixty digits, find the low-end coefficients $\mathsf{L}_0, \mathsf{L}_1, \mathsf{L}_2$ from the faces of the sectors, and check the output against the low-end relation and its first two derivatives.

(iv) Find the arc integrals $S_j = -\int_0^{2\pi/3} \log^{j-1}\left(2\sin\frac{\vartheta}{2}\right) d\vartheta$ for $j = 1, 2$.

Solution. Receipt: `ex20_gauge_end.py`. Theorem 40.6 applies: the ray has the origin 0 and positive walls, and (L) holds at every k with $\operatorname{Re} k > 0$ (Exercise 54.1, Step 5), in particular at all large integers; $f(\alpha^\star) = \frac{1}{9}$ is a simple root of the symbol $\chi(\lambda) = (1-\lambda)(1-9\lambda)$. Write $f^\star = \frac{1}{9}$.

Step 1: the density operator. With $\theta = t\,d/dt$ and $(p_0, p_1, p_2) = \big(k^2, -(10k^2{+}10k{+}3), 9(k{+}1)^2\big)$,

$$\begin{aligned}\sum_i t^i p_i(-1-i-\theta) &= (\theta+1)^2 - t\,(10\theta^2+30\theta+23) + 9t^2(\theta+2)^2 \\ &= t^2(t-1)(9t-1)\,\partial_t^2 + t\,(45t^2-40t+3)\,\partial_t + (36t^2-23t+1),\end{aligned}$$

of order $D = 2$, with the leading coefficient $(-1)^D t^D \chi(t)$; its singular points are 0, $\frac{1}{9}$, 1 and ∞. The second symbol is $\chi_1(\lambda) = -10\lambda + 18\lambda^2$.

Step 2: the exponents at $f^\star$. In $s = f^\star - t$ the operator is $b_2\partial_s^2 + b_1\partial_s + b_0$ with

$$b_2 = \tfrac{1}{81}s(9s-1)^2(9s+8), \qquad b_1 = \tfrac{1}{81}(9s-1)(405s^2+270s-8), \qquad b_0 = \tfrac{1}{9}(324s^2+135s-10),$$

so $b_{2,0} = 0$, $b_{2,1} = \frac{8}{81} = -(f^\star)^2\chi'(f^\star)$ and $b_{1,0} = \frac{8}{81}$. Theorem 40.6(i) gives $\gamma = D - 1 - b_{1,0}/b_{2,1} = 0$, which is $-1 + \chi_1(f^\star)/(f^\star\chi'(f^\star)) = -1 + \frac{-8/9}{-8/9}$, and $\frac{n-3}{2} = 0$ as Theorem 40.6(iii) requires. The polynomials $R_m(x) = \sum_j b_{j,m-1+j}[x]_j$ are

$$R_0 = \tfrac{8}{81}x^2, \qquad R_1 = -\tfrac{1}{9}(15x^2+23x+10), \qquad R_2 = (2x+3)(3x+5), \qquad R_3 = 9(x+2)^2,$$

and $R_m = 0$ for $m \geq 4$. The exponents at $s = 0$ are 0 and 0: one solution $\phi = \sum_m e_m s^m$, $e_0 = 1$, holomorphic at $s = 0$, with $R_0(N)e_N = -\sum_{m=1}^3 R_m(N-m)e_{N-m}$, and one of the form $\phi\log s + \psi$, ψ holomorphic with $\psi(0) = 0$.

Step 3: the line. For a germ v on $s > 0$ with $(b_2\partial_s^2 + b_1\partial_s + b_0)v = 0$, integration by parts on (ϵ, ∞) shows that the distribution $\mathfrak{D}(v\mathbf{1}_{s>0})$ pairs with a test function w as

$$\lim_{\epsilon\to 0^+}\Big[b_2\,(v'w - vw') + (b_1 - b_2')\,vw\Big]_{s=\epsilon}.$$

For $v = \phi$ this is $(b_{1,0} - b_{2,1})\,\phi(0)w(0) = 0$: ϕ extends by zero (Definition 40.4). For $v = \phi\log s + \psi$ the term $b_2 v'w$ tends to $b_{2,1}w(0)$, while the terms in $\log\epsilon$ have the coefficient $(b_{1,0} - b_{2,1})w(0) = 0$, so the pairing is $\frac{8}{81}w(0)$: the germ leaves a point mass $\frac{8}{81}\delta_{f^\star}$ and does not extend by zero, and neither does any germ with a logarithmic term. So the germs that extend by zero form the line of

ϕ (Theorem 40.6(ii)), the germ of ϱ_f spans it (Theorem 40.6(iii)), and $\varrho_f = \varrho_f(f^\star)\,\phi(f^\star - t)$ near $f^\star$, the case $\gamma \in \{0, \dots, D-2\}$ of Theorem 40.6(iv). In exact arithmetic

$$(e_m)_{m\ge 0} = 1,\ \tfrac{45}{4},\ \tfrac{3645}{32},\ \tfrac{70713}{64},\ \tfrac{21500397}{2048},\ \tfrac{807258879}{8192},\ \tfrac{15034997331}{16384},\ \tfrac{139237010559}{16384},\ \dots,$$

all positive.

Step 4: the value at the native value. By Theorem 38.15, on the centre ray the Hessian of $-\log f$ at $y = 0$ is twice the covariance matrix of the indicators of the marks $1, 2$ under the uniform law on the three marks,

$$H = 2\begin{pmatrix} \frac{2}{9} & -\frac{1}{9} \\ -\frac{1}{9} & \frac{2}{9} \end{pmatrix}, \qquad \det H = \tfrac{4}{27}.$$

By Definition 38.4 there are coordinates v near $y = 0$ with $\log f = \log f^\star - \frac{1}{2}|v|^2$, here real, with $dy = J(v)\,dv$ and $J(0) = (\det H)^{-1/2}$. So $\mu_f([t, f^\star]) = \int_{|v|\le\rho} J\,dv$ with $\rho^2 = 2\log(f^\star/t)$, whose derivative in ρ is $2\pi\rho J(0) + O(\rho^2)$, and $\varrho_f(t) = -\frac{d}{dt}\mu_f([t, f^\star]) = \frac{1}{\rho t}\big(2\pi\rho J(0) + O(\rho^2)\big)$, which tends to

$$\varrho_f(f^\star) = \frac{2\pi}{f^\star\sqrt{\det H}} = 2\pi \cdot 9 \cdot \frac{3\sqrt{3}}{2} = 27\sqrt{3}\,\Gamma(\tfrac{1}{2})^2.$$

Step 5: the values and the slopes. The other singular points of the operator lie at $s = \frac{1}{9}$ ($t = 0$) and $s = -\frac{8}{9}$, so the series ϕ converges on $|s| < \frac{1}{9}$, which contains $t \in (0, f^\star]$, and $\varrho_f(t) = 27\sqrt{3}\,\Gamma(\frac{1}{2})^2 \sum_m e_m(\frac{1}{9} - t)^m$ there: this series is the continuation of the germ along $(0, f^\star)$ in Theorem 40.6(v). Its terms are positive, so by monotone convergence Theorem 40.6(v) gives, for every real $K > 0$ and $j \in \mathbb{N}$,

$$P^{(j)}(K) = 27\sqrt{3}\,\Gamma(\tfrac{1}{2})^2 \sum_{m\ge 0} e_m\,\frac{\partial^j}{\partial a^j}\Big[9^{-a-m-1}\,\Gamma\,{}_{1}^{2}\begin{bmatrix} a+1,\ m+1 \\ a+m+2 \end{bmatrix}\Big]_{a=K},$$

the Beta corner $\int_0^{1/9} t^a(\frac{1}{9} - t)^m\,dt = 9^{-a-m-1}\Gamma\,{}_{1}^{2}\begin{bmatrix} a+1,\ m+1 \\ a+m+2 \end{bmatrix}$ and its derivatives in a through the digamma function and its derivatives. At $K = 150$ the terms fall below 10^{-150} times the first after 520 terms. Differentiated j times, (L) is $\sum_{l\le j}\binom{j}{l}\sum_i p_i^{(j-l)}(k)\,P^{(l)}(k+i) = 0$, an identity of meromorphic functions, solved for $P^{(j)}(k)$ because $p_0(k) = k^2 \ne 0$ at $k \ge 1$. The run from $K = 150, 151$ down to $k = 1$, at 140 digits, agrees with the run from $K = 200, 201$ to 138 digits. The output, rendered to sixty digits:

$$P(1) = \ell = 2.34390723868945889060156228887227706909540300963585626066\dots,$$
$$P'(1) = -8.07515226353164401026965124146737650134735782164232219222\dots,$$
$$P''(1) = 31.24865700624850564562564881961470385267564378216839540571\dots,$$

and $P(2) = 0.11463574622981963020052076295742568969846766987861875355 5\dots$, $P'(2) = -0.31664753731523294093363384099033569196227349182039350377 7\dots$ No datum of the low end enters.

Step 6: the low-end coefficients. $\mathsf{L}_0 = V_1 = 6$ (Definition 39.37), and $\mathsf{L}_1 = 0$ by Proposition 39.39, the weights being 1. For L_2 use the sector coordinates of an order π, $\alpha_{\pi(1)} = \rho$, $\alpha_{\pi(2)} = \rho q_2$, $\alpha_{\pi(3)} = \rho q_2 q_3$: then $K = \rho(1 + q_2 + q_2 q_3)$, $\Psi = \rho^2 q_2(1 + q_3 + q_2 q_3)$ and $e_3 = \rho^3 q_2^2 q_3$, so

$$f = q_2 q_3\,\varphi_\pi, \qquad \varphi_\pi = \big((1 + q_2 + q_2 q_3)(1 + q_3 + q_2 q_3)\big)^{-1}, \qquad \kappa_2 = \kappa_3 = 1,$$

the same for all six orders. In the formula of Proposition 39.39 at $i = 2$: $A = \varnothing$ gives $\frac{1}{2}\log^2\varphi_\pi(0) = 0$; $A = \{2\}$ gives, with $m = 1$, $\int_0^1 (\log\varphi_\pi)_{[\{2\}]}\, dq_2/q_2 = -\int_0^1 \log(1+q)\, dq/q$ and, with $m = 0$, nothing, $1_{[A]}$ being 0; $A = \{3\}$ gives the same as $\{2\}$; $A = \{2,3\}$ gives nothing. Expanding $\log(1+q)$,

$$\int_0^1 \log(1+q)\,\frac{dq}{q} = \sum_{m\geq 1}\frac{(-1)^{m-1}}{m^2} = \frac{1}{2}(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)),$$

so each order contributes $-(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ and $\mathsf{L}_2 = -6\,(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -\pi^2 = -\Gamma(\frac{1}{2})^4$, by the classical value $\sum_{m\geq 1} m^{-2} = \pi^2/6$.

Step 7: the output against the low end. By Definition 39.37, $k^2P(k) = \mathsf{L}_0 + \mathsf{L}_1 k + \mathsf{L}_2 k^2 + O(k^3)$ near 0, while $P(k+1)$ and $P(k+2)$ are holomorphic there. Expanding (L) at $k = 0$ to the orders 0, 1 and 2:

$$\mathsf{L}_0 - 3P(1) + 9P(2) = 0, \qquad \mathsf{L}_1 - 10P(1) - 3P'(1) + 18P(2) + 9P'(2) = 0,$$
$$\mathsf{L}_2 - 10P(1) - 10P'(1) - \tfrac{3}{2}P''(1) + 9P(2) + 18P'(2) + \tfrac{9}{2}P''(2) = 0.$$

The first is the low-end relation (Corollary 39.38(ii)). With $\mathsf{L}_0 = 6$, $\mathsf{L}_1 = 0$ and $\mathsf{L}_2 = -\Gamma(\frac{1}{2})^4$, the three left sides, read on the output of Step 5, are below $2\cdot 10^{-138}$ in modulus: the gauge end returns the low-end coefficients it did not use. The expansion at the orders 3 and 4 reads L_3 and L_4 off the output; they render as $4.80822761263837714159895264604579996 3\ldots$ and $15.48481981165258402025123201954778137 6\ldots$, and agree with $4\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ and $\frac{7}{60}\Gamma(\frac{1}{2})^8 + \frac{3}{4}\ell^2$ to 138 digits (a check).

Step 8: the arc integrals. $S_1 = -\frac{2\pi}{3} = -\frac{2}{3}\Gamma(\frac{1}{2})^2$. For S_2, expand $-\log\left(2\sin\frac{\vartheta}{2}\right) = \sum_{m\geq 1}\frac{\cos m\vartheta}{m}$ on $(0,2\pi)$, a series that converges in $L^2(0,2\pi)$ and so may be integrated term by term over $(0,x)$:

$$-\int_0^x \log\left(2\sin\tfrac{\vartheta}{2}\right)d\vartheta = \sum_{m\geq 1}\frac{\sin mx}{m^2} \qquad (0\leq x\leq 2\pi).$$

At $x = \frac{2\pi}{3}$, $\sin\frac{2\pi m}{3} = \frac{\sqrt{3}}{2}\chi(m)$ with $\chi(m) = 1, -1, 0$ for $m \equiv 1, 2, 0$ modulo 3, so

$$S_2 = \frac{\sqrt{3}}{2}\Big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{1+3\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{2+3\mathbb{Z}})((0,\infty))\Big),$$

which renders as $0.67662773760643575001413503618301352396 1\ldots$; $2\sqrt{3}\,S_2$ agrees with the value of ℓ of Step 5 to 140 digits, and Exercise 54.4 proves $\ell = 2\sqrt{3}\,S_2$.

Answer. The germ at $\frac{1}{9}$ is $\varrho_f(t) = 27\sqrt{3}\,\Gamma(\frac{1}{2})^2\sum_m e_m(\frac{1}{9}-t)^m$, holomorphic, the line of the germs that extend by zero; it holds on all of $(0,\frac{1}{9}]$. The values and slopes at 1 are the renderings above, the low-end coefficients are $\mathsf{L}_0 = 6$, $\mathsf{L}_1 = 0$, $\mathsf{L}_2 = -\Gamma(\frac{1}{2})^4$, and $S_1 = -\frac{2}{3}\Gamma(\frac{1}{2})^2$, $S_2 = \frac{\sqrt{3}}{2}\big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{1+3\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{2+3\mathbb{Z}})((0,\infty))\big)$. □

54.4 The torus at three marks

Exercise 54.4 (The torus at three marks)**.** Let F, P, ℓ, (L), the solution c and the closings x_j be as in Exercise 54.1, and S_2 as in Exercise 54.3. On the torus $\alpha_3 = 1$, $\alpha_1 = e^{i\vartheta_1}$, $\alpha_2 = e^{i\vartheta_2}$, let

$$T(k) = \frac{1}{(2\pi)^2}\int_{[0,2\pi]^2} |K|^{-2k}\, d\vartheta,$$

the torus value of the centre ray (Definition 40.11), wherever the integral converges.

(i) Show that T converges for $\operatorname{Re} k < 1$, satisfies (L), continues meromorphically, has $T(-j) = x_j$ and has a simple pole at $k = 1$ with the residue $R = -1/(\sqrt{3}\,\Gamma(\frac{1}{2})^2)$.

(ii) Show that $U(k) = 9^{1-k}T(1-k)$ satisfies (L), that $U(K) = c(K)$, and that $P(k)U(k+1) - P(k+1)U(k) = \frac{2}{3}\cdot 9^{1-k}/k^2$ for every k.

(iii) Show that $T = \dfrac{P}{2\Gamma(\frac{1}{2})^4} - \dfrac{\cot(\pi k)}{\sqrt{3}}\,U$.

(iv) Find the torus mean of $\log|K|$, and show that $\ell = 2\sqrt{3}\,S_2 = 3\big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{1+3\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{2+3\mathbb{Z}})((0,\infty))\big)$.

Solution. Receipt: `ex21_torus.py`.

Step 1: the stride on the torus. On the torus $\alpha^{-1} = \bar\alpha$, and $\Psi(\alpha) = e_3\,K(\alpha^{-1})$, so $\Psi = e_3\bar K$ and $f = e_3/(K\Psi) = |K|^{-2}$, real and at least $\frac{1}{9}$. Put $F = |K|^2 = 3 + 2\cos\vartheta_1 + 2\cos\vartheta_2 + 2\cos(\vartheta_1 - \vartheta_2)$. Its gradient $\big(-2\sin\vartheta_1 - 2\sin(\vartheta_1-\vartheta_2),\ -2\sin\vartheta_2 + 2\sin(\vartheta_1-\vartheta_2)\big)$ vanishes exactly when $\sin\vartheta_1 = -\sin\vartheta_2 = -\sin(\vartheta_1-\vartheta_2)$: either $\vartheta_2 = -\vartheta_1$ and $\sin\vartheta_1(1+2\cos\vartheta_1) = 0$, or $\vartheta_2 = \vartheta_1 + \pi$ and $\sin\vartheta_1 = 0$. So F has six critical points: $(0,0)$, the gauge $\mathbf{1}$, with $F = 9$, its maximum; $(\pi,0)$, $(0,\pi)$, (π,π), the signs, with $F = 1$; and the two zeros $z_\pm = (\frac{2\pi}{3}, \frac{4\pi}{3}), (\frac{4\pi}{3}, \frac{2\pi}{3})$ of K, where $F = Q(\delta) + O(|\delta|^3)$ in $\delta = \vartheta - \vartheta(z_\pm)$ with $Q(\delta) = \delta_1^2 - \delta_1\delta_2 + \delta_2^2$, of determinant $\frac{3}{4}$. In $u = \log f = -\log F$ the Hessian at $(0,0)$ is $H = \left(\begin{smallmatrix} 4/9 & -2/9 \\ -2/9 & 4/9 \end{smallmatrix}\right)$, of determinant $\frac{4}{27}$, the Hessian of Exercise 54.3, Step 4, read on the torus; at the signs it has the determinant -4 (Theorem 38.17(ii) read on the torus): they are nondegenerate saddles.

Step 2: convergence, the closings and the law. Near $z_\pm$, $|K|^{-2k}$ is of the size $|\delta|^{-2\operatorname{Re} k}$, integrable in two variables exactly when $\operatorname{Re} k < 1$; so T is holomorphic on $\operatorname{Re} k < 1$, with $|T(k)| \le T(\operatorname{Re} k)$. For $j \in \mathbb{N}$, $T(-j)$ is the mean of the Laurent polynomial $f^{-j} = |K|^{2j}$ over the torus, its constant term: $T(-j) = \mathrm{CT}(f^{-j}) = x_j$ (Definition 39.30). Multiply the certificate (C) of Exercise 54.1 by $f^k = \exp(k\log f)$, $\log f$ real on the torus off $z_\pm$: $\sum_e (k\,c_e + D_e)g_e \cdot f^k = \sum_e D_e(g_e f^k) = D_1H_1 + D_2H_2$ with $H_i = (g_i - g_3)f^k$ (Euler's identity, as in Step 5 there), and on the torus $D_e = -i\,\partial_{\vartheta_e}$. There $|\Psi| = |K|$, so $|g_e| \le C|K|^{-3}$, $|D_e g_e| \le C|K|^{-4}$ and $|c_e| \le C|K|^{-1}$; for $\operatorname{Re} k \le -3$ the H_i are C^1 on the torus and $\int \partial_{\vartheta_i} H_i\,d\vartheta = 0$. So (L) holds for T at $\operatorname{Re} k \le -3$, and by the identity theorem wherever $T(k)$, $T(k+1)$, $T(k+2)$ are holomorphic, $\operatorname{Re} k < -1$. Solved for $T(k+2)$, (L) continues T meromorphically to $\mathbb{C}$, with poles only at the positive integers; on $\operatorname{Re} k < 2$ the only possible pole is at 1, the argument of $T(k+2)$ at the zero $k = -1$ of $9(k+1)^2$.

Step 3: the residue at 1. Cut out the regions $Q(\delta) < \varepsilon^2$ around $z_\pm$. Off them the integrand is bounded for $\operatorname{Re} k \le \frac{3}{2}$, and on them $F^{-k} - Q^{-k} = O(|\delta|^{1-2\operatorname{Re} k})$ is integrable for $\operatorname{Re} k < \frac{3}{2}$; both give functions holomorphic near $k = 1$. And

$$\int_{Q(\delta)<\varepsilon^2} Q(\delta)^{-k}\,d\delta = \frac{2\pi}{\sqrt{3/4}}\int_0^\varepsilon r^{1-2k}\,dr = \frac{4\pi}{\sqrt{3}}\cdot\frac{\varepsilon^{2-2k}}{2-2k}.$$

Two zeros and the factor $(2\pi)^{-2}$ give $T(k) = \frac{1}{\sqrt{3}\,\pi}\cdot\frac{1}{1-k} + O(1)$ near 1: a simple pole with the residue $R = -1/(\sqrt{3}\,\pi) = -1/(\sqrt{3}\,\Gamma(\frac{1}{2})^2)$. Write $T(k) = R/(k-1) + T_0 + O(k-1)$.

Step 4: the torus read backwards. Read at $-k-1$, (L) for T is $(k+1)^2T(-k-1) - (10k^2 + 10k + 3)\,T(-k) + 9k^2T(1-k) = 0$. With $U(k) = 9^{1-k}T(1-k)$, $U(k+1) = 9^{-k}T(-k)$ and $U(k+2) = 9^{-k-1}T(-k-1)$,

$$\begin{aligned} k^2U(k) - (10k^2+10k+3)\,U(k+1) + 9(k+1)^2U(k+2) \\ = 9^{-k}\big(9k^2T(1-k) - (10k^2+10k+3)\,T(-k) + (k+1)^2T(-k-1)\big) = 0. \end{aligned}$$

So U solves (L), and $U(K) = 9^{1-K}x_{K-1} = c(K)$ (Exercise 54.1, Step 8). Its poles are at $0, -1, -2, \dots$, and $U(k) = -9R/k + O(1)$ at 0. It is the solution of the type of the signs: $c(K)$ decays like the native value 1, not like 9^{-K}.

Step 5: the frame of the chart and the torus. For meromorphic solutions X, Y of (L), $W(X,Y)(k) = X(k)Y(k+1) - X(k+1)Y(k)$ satisfies $p_2(k)W(k+1) = p_0(k)W(k)$ (substitute $p_2X(k+2) = -p_0X(k) - p_1X(k+1)$ and the same for Y; Proposition 38.11 with $h = 2$), so $k^2 9^{k-1}W(X,Y)(k)$ is periodic of period 1. A periodic function h of period 1, holomorphic on the strip $|\operatorname{Re} k| \le \frac12$ with $|h(k)| \le C(1+|k|)^N$ there, is constant: $h(k) = \mathcal{H}(e^{2\pi i k})$ with $\mathcal{H}$ holomorphic on $\mathbb{C}^\times$ and $|\mathcal{H}(z)| = O(|\log|z||^N)$ at 0 and at ∞, so both singularities are removable and $\mathcal{H}$ is constant by Liouville's theorem. On the strip, P is holomorphic except for its pole at 0, $P(k) = 6/k^2 + O(1)$ ($\mathsf{L}_0 = 6$, $\mathsf{L}_1 = 0$: Exercise 54.3, Step 6), and polynomially bounded, being continued from $\operatorname{Re} k > 0$, where $|P(k)| \le P(\operatorname{Re} k)$, by (L) solved for $P(k)$; $T(k)$ and $T(-k)$ are bounded; $T(k+1)$ and $T(1-k)$ have a simple pole at 0 only and are polynomially bounded, by (L).

(a) In $k^2 9^{k-1}W(P,U)$ the pole of $P(k)$ at 0 meets the holomorphic $U(k+1)$ and the simple pole of $U(k)$ meets the holomorphic $P(k+1)$, so the product with k^2 is holomorphic at 0: the function is constant, and at $k = 1$ it is $P(1)c(2) - P(2)c(1) = \frac{\ell}{3} - \frac{\ell-2}{3} = \frac23$. So

$$P(k)U(k+1) - P(k+1)U(k) = \frac{2}{3} \cdot \frac{9^{1-k}}{k^2} \qquad \text{for every } k,$$

the frame of the chart and the torus read backwards; at the integers it is the frame of r and c of Exercise 54.1, Step 8.

(b) Let $m_1 = (2\pi)^{-2} \int \log|K| \, d\vartheta$, so that $T(-k) = 1 + 2m_1 k + O(k^2)$ and $U(k+1) = 1 + (2m_1 - \log 9)\, k + O(k^2)$. Near 0, $P(k)U(k+1) = 6/k^2 + 6(2m_1 - \log 9)/k + O(1)$ and $P(k+1)U(k) = -9R\ell/k + O(1)$, while $\frac23 \cdot 9^{1-k}/k^2 = 6/k^2 - 6\log 9/k + O(1)$. The terms in $1/k$ give $12m_1 + 9R\ell = 0$:

$$m_1 = -\tfrac34 R\,\ell = \frac{\sqrt{3}\,\ell}{4\,\Gamma(\frac12)^2}.$$

Step 6: the connection up to one constant. $W(P,U) \neq 0$, so P and U are independent solutions and Cramer's rule on $T(k), T(k+1)$ gives $T = \alpha P + \beta U$ with $\alpha = W(T,U)/W(P,U)$ and $\beta = W(P,T)/W(P,U)$, periodic of period 1 by (a). First,

$$\alpha(k) = \tfrac{k^2}{6}\, T(k)T(-k) - \tfrac{3k^2}{2}\, T(k+1)T(1-k),$$

holomorphic on the strip, the double pole $T(k+1)T(1-k) = -R^2/k^2 + O(1)$ being cancelled by k^2, and polynomially bounded: α is constant, equal to its limit at 0, $\alpha = \frac32 R^2 = \frac{1}{2\pi^2} = \frac{1}{2\Gamma(\frac12)^4}$. Next,

$$\beta(k) = \tfrac{3k^2}{2}\, 9^{k-1}\big(P(k)T(k+1) - P(k+1)T(k)\big) = \frac{R}{k} + T_0 + R\log 9 + O(k) \qquad \text{near } 0,$$

from $P(k) = 6/k^2 + O(1)$ and $T(k+1) = R/k + T_0 + O(k)$. The function $R\,\pi\cot(\pi k)$ has simple poles at the integers with the residue R, so $\beta - R\,\pi\cot(\pi k)$ is periodic, entire and polynomially bounded on the strip, $\cot(\pi k)$ being bounded away from the real axis: it is a constant $b_0 = T_0 + R\log 9$. So

$$T = \frac{P}{2\Gamma(\frac12)^4} + \Big(b_0 - \frac{\cot(\pi k)}{\sqrt{3}}\Big)U.$$

Step 7: $b_0 = 0$, by the Fourier transform at the frequency 0. Put $t = e^u$. The image ν of $d\vartheta/(2\pi)^2$ under $u = -\log F$ is carried by $[u_0, \infty)$, $u_0 = -\log 9$, and has a density $n(u)$ with the following properties, by the Morse lemma at the nondegenerate critical points of Step 1 and the regularity of the other level sets: (a) near the maximum, $u - u_0 = \frac{1}{2}|v|^2$ in coordinates v with $d\vartheta = J\,dv$, $J(0) = (\det H)^{-1/2}$, so n is continuous on $[u_0, u_0 + \delta)$ with $n(u_0) = (2\pi)^{-2}\,2\pi J(0) = \frac{3\sqrt{3}}{4\pi} > 0$; in t, the density of the torus law at $\frac{1}{9}$ is $9\,n(u_0) = \frac{27\sqrt{3}}{4\pi} = (2\pi)^{-2}\varrho_f(\frac{1}{9})$, with $\varrho_f(\frac{1}{9})$ of Exercise 54.3; (b) near each saddle, $u = v_1 v_2$ in coordinates with $d\vartheta = \tilde{J}\,dv$, $\tilde{J}(0) = \frac{1}{2}$, the inverse square root of the modulus 4 of the determinant of the Hessian,, and the density of $v_1 v_2$ on $|v_1|, |v_2| < \delta$ at $s \neq 0$ is $\int_{|s|/\delta < |v_1| < \delta} \tilde{J}(v_1, s/v_1)\,dv_1/|v_1|$; writing $\tilde{J}(v) = \tilde{J}(0) + v_1 A(v) + v_2 B(v)$, this is $2\tilde{J}(0)\log(\delta^2/|s|)$ plus two integrals that converge, as $s \to 0$ from either side, to the same limits; so near $u = 0$, with the three saddles, $n(u) = -a\log|u| + b(u)$ with $a = 3 \cdot 2\tilde{J}(0)/(2\pi)^2 = \frac{3}{4\pi^2}$ and b continuous at 0; (c) near $z_\pm$, the nondegenerate minima of F, $n(u) = O(e^{-u})$, so $e^{cu}n(u)$ is integrable on $[u_0, \infty)$ for $0 < c < 1$.

Fix $c \in (0,1)$ and put $k = c + iy$, $y > 0$. Then $T(k) = \int e^{iyu}\psi(u)\,du$ with $\psi = e^{cu}n$; $P(k) = \int e^{iyu}\varphi(u)\,du$ with $\varphi(u) = e^{(c+1)u}\varrho_f(e^u)$, carried by $u \le u_0 < 0$; and, with $w = u_0 - u$ in $T(1-k)$, $U(k) = 9^{1-c}\int e^{iyw}\tilde{\psi}(w)\,dw$ with $\tilde{\psi}(w) = e^{(1-c)(u_0-w)}n(u_0 - w)$, carried by $w \le 0$. And $\beta(k) = b_0 + \frac{i}{\sqrt{3}} + O(e^{-2\pi y})$, as $\cot(\pi k) \to -i$.

Let χ be smooth with support in $[1,2]$ and $\int \chi = 1$, $g(s) = s\chi(s)$, $\hat{g}(w) = \int g(s)e^{isw}ds$, rapidly decreasing, and for a function Φ of y put $M_Y[\Phi] = Y^{-1}\int \Phi(y)\,y\,\chi(y/Y)\,dy$. For $\Phi(y) = \int e^{iyu}\psi(u)\,du$ with ψ integrable, Fubini gives $M_Y[\Phi] = \int \psi(w/Y)\,\hat{g}(w)\,dw$. Now $\int \hat{g} = 2\pi g(0) = 0$, $\int_0^\infty \hat{g} = i\int g(s)\,s^{-1}ds = i$, $\int_{-\infty}^0 \hat{g} = -i$, and $\int \log|w|\,\hat{g}(w)\,dw = -\pi$ (with $\hat{g} = -i\hat{\chi}'$, integrate by parts and use $\mathrm{PV}\int e^{isw}dw/w = i\pi$ for $s > 0$). So, as $Y \to \infty$: if ψ is bounded near 0 with one-sided limits $\psi(0\pm)$, $M_Y[\Phi] \to i\big(\psi(0+) - \psi(0-)\big)$; if $\psi = -a\log|u| + b(u)$ near 0 with b continuous at 0, $M_Y[\Phi] \to \pi a$.

Apply M_Y to the connection along $k = c + iy$. The torus value gives πa, by (b). The values give 0, φ vanishing near 0. The last term gives $\big(b_0 + \frac{i}{\sqrt{3}}\big)\,9^{1-c}\,i\big(0 - \tilde{\psi}(0-)\big)$, the factor $O(e^{-2\pi y})$ of β contributing nothing in the limit, with $9^{1-c}\tilde{\psi}(0-) = 9^{1-c}e^{(1-c)u_0}n(u_0) = n(u_0)$. With $Q = n(u_0) > 0$:

$$\pi a = \Big(b_0 + \frac{i}{\sqrt{3}}\Big)(-i)\,Q = \frac{Q}{\sqrt{3}} - i\,b_0 Q.$$

a, b_0 and Q are real, so $b_0 = 0$ (and $\pi a = Q/\sqrt{3}$: both are $\frac{3}{4\pi}$). Hence (iii), and $T_0 = -R\log 9 = \dfrac{2\log 3}{\sqrt{3}\,\Gamma(\frac{1}{2})^2}$.

Step 8: what the connection carries. (a) At $k = 1 + j$, $j \ge 0$, P and U are holomorphic and $-\cot(\pi k)/\sqrt{3}$ has the residue $-1/(\sqrt{3}\,\pi)$, so $\mathrm{Res}_{k=1+j}\,T = -\frac{9^{-j}x_j}{\sqrt{3}\,\Gamma(\frac{1}{2})^2}$: the poles of the torus value carry its values at the negative integers. (b) Near 0, $P = 2\Gamma(\frac{1}{2})^4\big(T + \frac{\cot(\pi k)}{\sqrt{3}}U\big)$ and $\frac{\cot(\pi k)}{\sqrt{3}}U = \frac{1}{\sqrt{3}\pi k}\cdot\frac{-9R}{k} + O(\frac{1}{k}) = \frac{3}{\pi^2 k^2} + O(\frac{1}{k})$: the low-end coefficient $\mathsf{L}_0 = 6$ is the residue of the torus at the zeros of K. (c) For real $a \ge 0$, $a \neq 1$, the mean of $\log|a + e^{i\vartheta}|$ over ϑ is $\log\max(a,1)$ (for $a > 1$ write $\log|a + e^{i\vartheta}| = \log a + \mathrm{Re}\log(1 + e^{i\vartheta}/a)$, whose second term is a power series in $e^{i\vartheta}$ without constant term; for $a < 1$ the same with $\log|1 + ae^{-i\vartheta}|$). Integrating over ϑ_1 first, with $a = |1 + e^{i\vartheta_2}| = 2|\cos\frac{\vartheta_2}{2}|$, which exceeds 1 exactly when $|\vartheta_2| < \frac{2\pi}{3}$,

$$m_1 = \frac{1}{\pi}\int_0^{2\pi/3} \log\big(2\cos\tfrac{\vartheta}{2}\big)\,d\vartheta = -\frac{1}{\pi}\int_0^{\pi/3} \log\big(2\sin\tfrac{\varphi}{2}\big)\,d\varphi = \frac{1}{\pi}\sum_{m\ge 1}\frac{\sin(m\pi/3)}{m^2},$$

by $\vartheta = \pi - \varphi$, $\int_0^\pi \log(2\sin\frac{\varphi}{2})\,d\varphi = 0$ and the Fourier series of Exercise 54.3, Step 8. Here $\sin\frac{m\pi}{3} = \frac{\sqrt3}{2}\varepsilon(m)$ with $\varepsilon(m) = 1,1,0,-1,-1,0$ for $m \equiv 1,\dots,6$ modulo 6, and $\varepsilon(m) = \chi(m)$ for odd m, $-\chi(m)$ for even m, χ as in Exercise 54.3; $\chi(2m) = -\chi(m)$, so $\sum_m \varepsilon(m)m^{-2} = \sum_m \chi(m)m^{-2} + \frac12\sum_m \chi(m)m^{-2}$, and $m_1 = \frac{3\sqrt3}{4\pi}\sum_m \chi(m)m^{-2} = \frac{3}{2\pi}S_2$. With Step 5(b):

$$\ell = \frac{4\pi m_1}{\sqrt3} = 2\sqrt3\,S_2 = 3\Big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{1+3\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{2+3\mathbb{Z}})((0,\infty))\Big).$$

Checks (floating point, not part of the solution). By the mean over one circle, $T(k) = \frac{2}{\pi}\int_0^2 I_k(a)\,\frac{da}{\sqrt{4-a^2}}$ with $I_k(a)$ the mean of $|a+e^{i\vartheta}|^{-2k}$, a hypergeometric series in a^2 or a^{-2}; this gives $T(-j) = x_j$, (L) on T at $k = -1.3$ and $k = -2.7+0.4i$ to 20 digits, and, with P from the gauge end, the connection of (iii) at $k = 0.2, 0.3, \dots, 0.8$ to between 17 and 23 digits, $k^2 9^{k-1}W(P,U) = \frac23$ at the same points to 20 digits, $\beta(\frac12) = b_0$ below $2\cdot10^{-23}$, and T_0 rendering as $0.40379779973879724450\ldots$; m_1 renders as $0.32306594721945051409363651072 4\ldots$

Answer. T continues to a meromorphic solution of (L) with $T(-j) = x_j$ and the residue $-1/(\sqrt3\,\Gamma(\frac12)^2)$ at 1; $U(k) = 9^{1-k}T(1-k)$ is the solution c of Exercise 54.1, with $P(k)U(k+1) - P(k+1)U(k) = \frac23\cdot 9^{1-k}/k^2$; the connection is $T = \frac{P}{2\Gamma(\frac12)^4} - \frac{\cot(\pi k)}{\sqrt3}U$; the torus mean of $\log|K|$ is $\frac{\sqrt3\,\ell}{4\Gamma(\frac12)^2}$, and $\ell = 2\sqrt3\,S_2 = 3\big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{1+3\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{2+3\mathbb{Z}})((0,\infty))\big)$. □

54.5 A lean of three marks

Exercise 54.5 (The lean $(2\mathbf{1};4,1)$ of $\binom{[3]}{1}$)**.** Let F and ℓ be as in Exercise 54.1, and consider the ray of F with the origin 0 and the direction $(2\mathbf{1};4,1)$, with the values $P_\lambda(k) = P_F(2k\mathbf{1};4k,k)$.

(i) Find its walls, V_1, its stride and native value, and its closings.

(ii) Reduce its box $\mathfrak{B}_2(1,1)$ modulo the permutations of the marks: the spanning set at $\mathfrak{s} = 1$, the matrix, the law of [1], its symbol and its native gauges, and $\mathbf{B}(\infty)$.

(iii) Read the low-end relation, and show that $54\,P_\lambda(1) = 11 - 4\ell$.

(iv) Write $P_\lambda(1)$ on the share side, and say why the gap theorem cannot be applied to the rational coordinates of this ray.

Solution. Receipt: `ex22_lean.py`.

Step 1: the ray. By Definition 8.1 and the counts of Exercise 54.1, Step 1, the walls of the direction are $\kappa_{1,S} = m_S - 4d(S) - d^*(S) = m_S - (|S|-1)$: 2 on the marks and 3 on the pairs. Every order π has the tails U_2, a pair, and U_3, a mark, so $V_1 = 6\cdot\frac{1}{3\cdot2} = 1$ (Proposition 39.34). The stride is $f = \alpha^{2\mathbf{1}}K^{-4}\Psi^{-1} = e_3^2/(e_1^4e_2)$. The defects $c_e = 2 - 4R_e - R_e^*$ vanish at $\mathbf{1}$ $(2 - \frac43 - \frac23 = 0)$, so $\alpha^\star = \mathbf{1}$ and $f(\alpha^\star) = \frac{1}{3^4\cdot3} = \frac{1}{243}$. The constant term of $f^{-j} = e_1^{4j}\big(\sum_e \alpha^{\mathcal{E}\setminus e}\big)^j\alpha^{-2j\mathbf{1}}$ pairs the monomial $\alpha^{(j-b_1,j-b_2,j-b_3)}$ of the second factor with the monomial $\alpha^{(j+b_1,j+b_2,j+b_3)}$ of e_1^{4j}, so

$$x_j = \mathrm{CT}(f^{-j}) = (4j)!\,j!\sum_{b_1+b_2+b_3=j}\ \prod_{e=1}^{3}\frac{1}{b_e!\,(b_e+j)!},$$

$$(x_j)_{j\ge0} = 1,\ 36,\ 4620,\ 762300,\ 140216076,\ 27409661136,\ \ldots$$

Step 2: the box. The permutations of the marks are symmetries; the Cremona is not, the exponents 4 and 1 being different (Proposition 39.11(ii)). Modulo S_3 the box $\mathfrak{B}_2(1,1)$ (Definition 39.15), the box with one unit of each letter at $\mathfrak{t} = 2$, has 398 symbols in 79 orbits (17, 19, 20

and 23 at the levels $(0,0)$, $(1,0)$, $(0,1)$, $(1,1)$) and 82 stems. Its relations are 184 letter identities for K, 178 for Ψ and 246 mark relations of stems; modulo S_3 they give 117 distinct combinations of orbit averages, of rank 76. The free orbits are those of $\alpha_1\alpha_2\alpha_3/(K\Psi)$ (wall degree $-\frac{1}{3}$), of α_1/α_3 (wall degree $\frac{1}{2}$) and of 1, so the spanning set at $\mathfrak{s}=1$ is again $(1,b_1)$, $b_1=\frac{1}{6}\sum_{i\neq j}\alpha_i/\alpha_j$, and the box is accepted there (Definition 39.20) with

$$\mathbf{B}_{11}=\frac{199k^3-420k^2+299k-72}{(k-1)^2(3k-2)},\qquad \mathbf{B}_{12}=\frac{(2k-1)(265k^2-424k+171)}{(k-1)^2(3k-2)},$$
$$\mathbf{B}_{21}=\frac{3710k^4-12349k^3+15022k^2-7997k+1584}{3(k-1)(2k-3)(3k-4)(3k-2)},$$
$$\mathbf{B}_{22}=\frac{(2k-1)(4706k^3-13323k^2+12238k-3681)}{3(k-1)(2k-3)(3k-4)(3k-2)}.$$

Certificates on the stems (Theorem 39.21(ii)): for each row, G_1 a combination of the stems symmetric under the exchange of the marks 2 and 3, G_e its images; the identity is linear in 44 unknowns with 118 equations and a family of solutions of dimension 24; a solution with 20 nonzero coefficients, rational functions of k, satisfies it exactly for each row. It is not displayed here; the receipt prints it.

Step 3: the law. The rows of Proposition 39.6 give the first dependence with

$$q_0=-972(k-1)^2(4k-3)(4k-1)(265k^2-954k+860),$$
$$q_1=-1721705k^6+13084958k^5-40594556k^4+65762882k^3$$
$$-58662047k^2+27325016k-5197140,$$
$$q_2=3(k-2)^2(3k-5)(3k-4)(265k^2-424k+171),$$

and $p_j(k)=q_{2-j}(k+2)$, divided by their common factor, is the recurrence

$$-3k^2(3k+1)(3k+2)(265k^2+636k+383)\,P_\lambda(k)$$
$$+(1721705k^6+7575502k^5+13047276k^4+11068046k^3+4766659k^2+965100k+75600)\,P_\lambda(k+1)$$
$$+972(k+1)^2(4k+5)(4k+7)(265k^2+106k+12)\,P_\lambda(k+2)=0,$$

of degree 6, with the symbol $265(243\lambda-1)(64\lambda+27)$; its reflection is satisfied by the closings of Step 1 (Corollary 39.38(i)). The native gauges: at $\mathbf{1}$ the native value $\frac{1}{243}$, and the Hessian of $\log f$ on the chart $\alpha_3=1$ has the determinant $\frac{25}{27}$; at $\alpha=(3,3,-2)$ and its permutations all three defects vanish (exact evaluation), the native value is $\frac{(-18)^2}{4^4\cdot(-3)}=-\frac{27}{64}$, and the Hessian has the determinant $-\frac{75}{2}$. Both are nondegenerate, their native values are the roots of the symbol (Corollary 38.7), and the vectors $(1,b_1(\alpha_c))$ are $(1,1)$ and $(1,-\frac{7}{18})$, which span: by Proposition 39.42(i) the spanning set is a set of masters and the recurrence is the law of [1]. Finally

$$\mathbf{B}(\infty)=\begin{pmatrix}\frac{199}{3} & \frac{530}{3}\\ \frac{1855}{27} & \frac{4706}{27}\end{pmatrix},$$

with the eigenvalues 243 and $-\frac{64}{27}$ and the eigenvectors $(1,1)$ and $(1,-\frac{7}{18})$ (Proposition 39.42(ii)).

Step 4: the low-end relation. p_0 vanishes to the order 2 at 0 with $[k^2]p_0=-3\cdot1\cdot2\cdot383=-2298$, $p_1(0)=75600$ and $p_2(0)=972\cdot5\cdot7\cdot12=408240$; with $\mathsf{L}_0=V_1=1$, Corollary 39.38(ii) gives $-2298+75600\,P_\lambda(1)+408240\,P_\lambda(2)=0$, that is

$$12600\,P_\lambda(1)+68040\,P_\lambda(2)=383.$$

Step 5: the value, read on the centre ray. At $k=2$ the centre ray of Exercise 54.1 has the stride $f_{\mathrm{c}}=\alpha^{\mathbf{1}}/(K\Psi)$, and

$$\big\langle \Psi K^{-2}\big\rangle_2=\int \Psi K^{-2}\,\frac{\alpha^{\mathbf{21}}}{K^2\Psi^2}\,dy=\int \frac{\alpha^{\mathbf{21}}}{K^4\Psi}\,dy=P_\lambda(1):$$

the value of the lean is the value of the insertion $\Psi K^{-2}=\sum_e \alpha^{\mathcal{E}\setminus e}K^{-2}$ along the centre ray. In the box $\mathfrak{B}_2(2,2)$ of the centre ray modulo S_3 and the Cremona (339 symbols, 43 orbits, 499 relations of rank 40, the free orbits those of f_{c}^2, of α_1/α_3 and of 1) the orbit average of ΨK^{-2} reduces to

$$\Psi K^{-2}\equiv -\frac{2(k-1)}{3(k+1)}+\frac{(k-1)^2}{k(k+1)}\,b_1.$$

The relations of a box evaluate into $\mathcal{L}$ and their values vanish identically in k (Proposition 39.18(i)); the symmetries keep the values (Proposition 39.11(ii)); and at $k=2$ every value involved converges. So, with $\langle b_1\rangle_k=\frac{1}{6}\big(\langle f_{\mathrm{c}}^{-1}\rangle_k-3\langle 1\rangle_k\big)=\frac{1}{6}\big(P(k{-}1)-3P(k)\big)$ from $f_{\mathrm{c}}^{-1}=3+6b_1$, $\langle b_1\rangle_2=\frac{1}{6}\big(\ell-(\ell-2)\big)=\frac{1}{3}$, and

$$P_\lambda(1)=-\frac{2}{9}\,P(2)+\frac{1}{6}\cdot\frac{1}{3}=-\frac{2}{9}\cdot\frac{\ell-2}{3}+\frac{1}{18}=\frac{11-4\ell}{54}.$$

Then Step 4 gives $P_\lambda(2)=\frac{2800\ell-6551}{204120}$, and the law gives every $P_\lambda(K)$ in $\mathbb{Q}+\mathbb{Q}\ell$.

Step 6: the share side. By Proposition 8.15, $P_F(\mathbf{m};s,t)$ is the period of the dual table, whose bases are the sets $\mathcal{E}\setminus e$, at the exponents (t,s); that table is one circuit, and Corollary 18.24 with the exponents $(1,4)$, $\nu_e=m_e-1=1$ and unit weights (its condition $m_S>|S|-1$ holds: $2>0$, $4>1$) gives

$$P_\lambda(1)=\frac{1}{\Gamma(4)\Gamma(1)}\int_0^\infty \mathsf{G}_{1;(1,-1)}(1,y)^3\,dy,$$

that is $\frac{1}{6}\int_0^\infty \mathsf{G}_{1;(1,-1)}(1,y)^3\,dy$. A check by quadrature: both this integral and $\frac{11-4\ell}{54}$ render as $0.03008094528226230439988427489834 9847\ldots$

Step 7: why the gap does not apply. Write $P_\lambda(K)=c_\lambda(K)\,\ell+r_\lambda(K)$ with rationals from Steps 3 to 5, and let D_K be the least common denominator of $c_\lambda(K)$ and $r_\lambda(K)$, the least integer that clears the row. Theorem 37.2 needs $D_KP_\lambda(K)\to 0$. But the values decay no faster than 243^{-K}: as in Exercise 54.1, Step 2(b), $f\ge\frac{1}{243}\,\alpha_{(2)}\alpha_{(3)}^2/\alpha_{(1)}^3$, and on the cone of an order the exponent $3y_{(1)}-y_{(2)}-2y_{(3)}=3(y_{(1)}-y_{(2)})+2(y_{(2)}-y_{(3)})$ has the walls 3 and 2 as coefficients, so $P_\lambda(K)\ge 243^{-K}\cdot 6\cdot\frac{1}{6K^2}=243^{-K}/K^2$. The exact denominators satisfy $D_K>243^KK^2$ for every K with $3\le K\le 240$, so $D_KP_\lambda(K)>1$ throughout that range; $\frac{1}{K}\log D_K$ renders as about 10.3 at $K=240$, against $\log 243=5.49$. The clearing integers of this ray grow faster than its values decay, and the hypothesis of Theorem 37.2 fails on every computed row.

Answer. Walls 2 and 3, $V_1=1$, $f(\alpha^\star)=\frac{1}{243}$; the masters $1,b_1$, the law above with the symbol $265(243\lambda-1)(64\lambda+27)$ and the native gauges $\mathbf{1}$ and $(3,3,-2)$; the low-end relation $12600P_\lambda(1)+68040P_\lambda(2)=383$; and $54\,P_\lambda(1)=11-4\ell$, with the share side $\frac{1}{6}\int_0^\infty \mathsf{G}_{1;(1,-1)}(1,y)^3dy$. □

54.6 The balanced directions

Exercise 54.6 (The balanced directions of $\binom{[3]}{1}$)**.** Let F and ℓ be as in Exercise 54.1. For a direction $(\mathbf{m};s,t)$ on the balance wall put $c_e=m_e-t$.

(i) List the balanced directions with $1\le s,t\le 5$, positive walls and $m_1\ge m_2\ge m_3$, and sort them by $S=s+t$ and the multiset $\{|c_e|\}$.

(ii) Show that $\Gamma(sk)\Gamma(tk)\,P_F(k\mathbf{m};ks,kt)$ depends on the direction only through S and $\{|c_e|\}$, so that within a class the values are in the ratio of two Beta corners.

(iii) For every direction with $|c_e|$ constant find $P_F(\mathbf{m};s,t)$ in $\mathbb{Q}+\mathbb{Q}\ell$, and its native value $f(\alpha^\star)$.

Solution. Receipt: `ex23_directions.py`.

Step 1: the directions. The balance wall is $m_{\mathcal{E}} = s+2t$, and the walls are $\kappa_S = m_S - t(|S|-1)$ (Exercise 54.5, Step 1): $m_e > 0$ and $m_e + m_{e'} > t$. There are 123 such directions. The multiset $\{|c_e|\}$, with $\sum_e c_e = s-t$, has one value on 17 of them, two on 70 and three on 36; the classes of equal S and $\{|c_e|\}$ number 54: 9, 31 and 14. The 17 directions with $|c_e|$ constant fall into nine classes:

$\lvert c_e\rvert$, S	directions $(\mathbf{m};s,t)$	$P_F(\mathbf{m};s,t)$
0, $2c'$	$(c'\mathbf{1};c',c')$, $c'=1,\dots,5$	$\ell,\ \frac{\ell-2}{3},\ \frac{10\ell-23}{54},\ \frac{62\ell-145}{486},\ \frac{568\ell-1331}{5832}$
1, 5	$(4,2,2;2,3)$, $(3,3,1;3,2)$	$\frac{11-4\ell}{18}$
	$(3,3,3;1,4)$, $(2,2,2;4,1)$	$\frac{11-4\ell}{54}$
1, 7	$(5,3,3;3,4)$, $(4,4,2;4,3)$	$\frac{19-8\ell}{54}$
	$(4,4,4;2,5)$, $(3,3,3;5,2)$	$\frac{19-8\ell}{108}$
1, 9	$(6,4,4;4,5)$, $(5,5,3;5,4)$	$\frac{751-320\ell}{2916}$
2, 8	$(7,3,3;3,5)$, $(5,5,1;5,3)$	$\frac{80\ell-181}{648}$

the last column being found in Step 3.

Step 2: the classes. The walls are positive, so Proposition 8.15 and Corollary 18.24 apply as in Exercise 54.5, Step 6, at the data $(k\mathbf{m};ks,kt)$, with $\nu_e = km_e - kt = kc_e$:

$$\Gamma(sk)\Gamma(tk)\,P_F(k\mathbf{m};ks,kt) = \int_0^\infty y^{tk-1}\prod_e \mathsf{G}_{kc_e;(1,-1)}(1,y)\,dy.$$

Proposition 2.3 with $A=1$ and $\mathbf{h}=\frac12\log y$ gives $\mathsf{G}_{\nu;(1,-1)}(1,y) = y^{\nu/2}\,\mathsf{G}_{\nu;(1,-1)}(\sqrt{y},\sqrt{y})$, and with $A=-1$ it gives $\mathsf{G}_{\nu;(1,-1)}(\xi_1,\xi_2) = \mathsf{G}_{-\nu;(1,-1)}(\xi_2,\xi_1)$, so at equal coefficients the Gramma is even in ν. With $\sum_e c_e = s-t$,

$$\Gamma(sk)\Gamma(tk)\,P_F(k\mathbf{m};ks,kt) = \int_0^\infty y^{\frac{Sk}{2}-1}\prod_e \mathsf{G}_{k|c_e|;(1,-1)}(\sqrt{y},\sqrt{y})\,dy,$$

which depends on S and $\{|c_e|\}$ only. So two directions d,d' of one class have

$$\frac{P_{d'}(k)}{P_d(k)} = \frac{\Gamma(sk)\Gamma(tk)}{\Gamma(s'k)\Gamma(t'k)} = \Gamma_{\,1}^{\,2}\!\begin{bmatrix} sk,\ tk \\ Sk \end{bmatrix} \Big/ \Gamma_{\,1}^{\,2}\!\begin{bmatrix} s'k,\ t'k \\ Sk \end{bmatrix},$$

two Beta corners at the same total, rational at the integers; for instance $\frac{\Gamma(4k)\Gamma(k)}{\Gamma(3k)\Gamma(2k)} = 3, 7, \frac{33}{2}, 39$ at $k=1,2,3,4$ for $(4,2,2;2,3)$ against $(3,3,3;1,4)$. A class has one value span.

Step 3: the values, read on the centre ray. Along the centre ray of Exercise 54.1, with $f_{\mathrm{c}} = \alpha^{\mathbf{1}}/(K\Psi)$, the insertion $\alpha^u K^{-a}\Psi^{-b}$ has the value $\langle \alpha^u K^{-a}\Psi^{-b}\rangle_k = P_F(k\mathbf{1}+u;k+a,k+b)$ (Definition 38.1). So

$$P_F(k\mathbf{1}+2\mathbf{e}_1;k,k+1) = \langle \alpha_1^2\Psi^{-1}\rangle_k, \qquad P_F(3\mathbf{1}+4\mathbf{e}_1;3,5) = \langle \alpha_1^4\Psi^{-2}\rangle_3,$$

and $(4,2,2;2,3)$, $(5,3,3;3,4)$, $(6,4,4;4,5)$ are $\langle \alpha_1^2\Psi^{-1}\rangle_k$ at $k=2,3,4$. Reduced in the boxes of the centre ray modulo S_3 and the Cremona, as in Exercise 54.2 (the orbit averages have the same values, Proposition 39.11(ii)),

$$\alpha_1^2\Psi^{-1} \equiv -\frac{2}{3} + \frac{k-1}{k}\,b_1 \quad \text{in } \mathfrak{B}_2(1,1),$$

$$\alpha_1^4\Psi^{-2} \equiv \frac{7k+5}{9(k+1)} - \frac{(k-1)(2k^2-6k-5)}{3k(k-2)(k+1)}\, b_1 \quad \text{in } \mathfrak{B}_2(2,2),$$

and the relations of a box hold at every strength where the values converge (Proposition 39.18(i)). With $P(K) = c(K)\ell + r(K)$ (Exercise 54.1, Step 8) and $\langle b_1\rangle_k = \frac{1}{6}\big(P(k-1) - 3P(k)\big)$, so that $\langle b_1\rangle_2 = \frac{1}{3}$, $\langle b_1\rangle_3 = \frac{11-4\ell}{108}$ and $\langle b_1\rangle_4 = \frac{19-8\ell}{243}$,

$$P_F(4,2,2;2,3) = -\tfrac{2}{3}\cdot\tfrac{\ell-2}{3} + \tfrac{1}{2}\cdot\tfrac{1}{3} = \tfrac{11-4\ell}{18}, \qquad P_F(5,3,3;3,4) = -\tfrac{2}{3}\cdot\tfrac{10\ell-23}{54} + \tfrac{2}{3}\cdot\tfrac{11-4\ell}{108} = \tfrac{19-8\ell}{54},$$
$$P_F(6,4,4;4,5) = -\tfrac{2}{3}\cdot\tfrac{62\ell-145}{486} + \tfrac{3}{4}\cdot\tfrac{19-8\ell}{243} = \tfrac{751-320\ell}{2916},$$
$$P_F(7,3,3;3,5) = \tfrac{13}{18}\cdot\tfrac{10\ell-23}{54} + \tfrac{5}{18}\cdot\tfrac{11-4\ell}{108} = \tfrac{80\ell-181}{648}.$$

The centre's class is the centre ray read at $c'k$: $P_F(c'\mathbf{1}; c', c') = P(c') = c(c')\ell + r(c')$. The other members follow by the ratios of Step 2 at $k=1$: $\frac{\Gamma(2)\Gamma(3)}{\Gamma(3)\Gamma(2)} = 1$ for $(3,3,1;3,2)$, $\frac{\Gamma(2)\Gamma(3)}{\Gamma(1)\Gamma(4)} = \frac{1}{3}$ for $(3,3,3;1,4)$ and $(2,2,2;4,1)$, 1 for $(4,4,2;4,3)$, $\frac{\Gamma(3)\Gamma(4)}{\Gamma(2)\Gamma(5)} = \frac{1}{2}$ for $(4,4,4;2,5)$ and $(3,3,3;5,2)$, and 1 for $(5,5,3;5,4)$ and $(5,5,1;5,3)$. The value of $(2,2,2;4,1)$ agrees with Exercise 54.5, where it was read on another insertion.

Step 4: the native values. The native gauge on the orthant is unique (Theorem 38.14(i)), so a symmetry of the masses fixes it: for $m_2 = m_3$ it is $(x,1,1)$, for $m_1 = m_2$ it is $(1,1,x)$, with $x > 0$ the root of the defect equation $m_e = s\,\alpha_e/K + t\,\alpha_e(K-\alpha_e)/\Psi$ at one mark. Exactly: $f(\alpha^\star) = 9^{-c'}$ on the centre's class; $\frac{1}{243}$ at $\mathbf{1}$ for $(3,3,3;1,4)$ and $(2,2,2;4,1)$, and $\frac{64}{6561}$ at $(4,1,1)$ and $(1,1,\frac{1}{4})$ for $(4,2,2;2,3)$ and $(3,3,1;3,2)$; $\frac{1}{2187}$ at $\mathbf{1}$ for $(4,4,4;2,5)$ and $(3,3,3;5,2)$, and $\frac{3125}{3779136}$ at $(\frac{5}{2},1,1)$ and $(1,1,\frac{2}{5})$; $\frac{1}{12500}$ at $(2,1,1)$ and $(1,1,\frac{1}{2})$; $\frac{823543}{553584375}$ at $(7,1,1)$ and $(1,1,\frac{1}{7})$. Within a class the native values are in the ratio of the rates of the Beta corners, $\frac{64}{27} = \frac{4^4}{3^3 2^2}$ and $\frac{3125}{1728} = \frac{5^5 2^2}{4^4 3^3}$.

Check (not part of the solution). The least recurrences of the closings $\mathrm{CT}(f^{-j})$, searched by linear algebra modulo the prime $2^{61}-1$ on 60 closings to the order 4 and the degree 24, have the order 2 on 16 of the 17 directions with $|c_e|$ constant; on the seventeenth, $(5\mathbf{1};5,5)$, the closings are those of the centre at $5j$, whose recurrence of order 2 has the degree 18, found with 70 closings. They have the order 3 on 5 directions and the order 4 on 2, all with two values of $|c_e|$, and none within these bounds on the other 100.

Answer. 123 directions in 54 classes; within a class $\Gamma(sk)\Gamma(tk)P$ is one function of k, and the values are in the ratio of two Beta corners at the same total; the 17 directions with $|c_e|$ constant have the values of the table, all in $\mathbb{Q} + \mathbb{Q}\ell$, and the native values of Step 4. □

54.7 The centre of $\binom{[4]}{1}$

The list $\binom{[4]}{1}$ has the marks $1,2,3,4$ and the four singletons as its bases, every weight 1, so that $K(\alpha) = \alpha_1+\alpha_2+\alpha_3+\alpha_4$ and $\Psi(\alpha) = \alpha^{[4]}K(\alpha^{-1})$. Its centre ray at the strength one (Definition 38.13) has the stride $f = \big(K(\alpha)K(\alpha^{-1})\big)^{-1}$, so that $f^{-1} = \sum_{e,e'} \alpha_e/\alpha_{e'}$; the walls of the direction are the widths, $\kappa_{1,S} = r(S) + r([4]\setminus S) - 1 = 1$ for every nonempty proper S, and the volume of the direction is $V_1 = \sum_\pi \prod_{l=2}^4 \kappa_{1,U_l}^{-1} = 4! = 24$ (Proposition 39.34). Its values are $P(k) = \langle 1\rangle_k = P_{\binom{[4]}{1}}(k\mathbf{1}; k, k)$, and throughout this section $v = P(1)$. The five exercises close v on the half-lattice, derive the law of the values and its rows, write the row at every step in closed form, read the coefficient of the coordinate as a closing in two ways, and clear the rows.

Exercise 54.7 (The closing on the half-lattice)**.** Write $v = P(1)$ on its share side, merge the marks in pairs, and close the remaining share. Show that

$$v = (\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac{1}{2}+\mathbb{Z}})((0,\infty)) = 7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)).$$

Solution. Receipt: `ex24a_halflattice.py`.

The share side. The dual list $\binom{[4]}{3}$ has the bases $[4]-e$, and replacing the table by its dual exchanges the exponents (Proposition 8.15), which at the centre are equal: the two lists have the same values. Corollary 18.24 applies to $\binom{[4]}{3}$ at $s=t=1$ with the masses $\mathbf{1}$: they lie on the balance wall, $m_{[4]}=4=3s+t$, they meet $m_S=|S|>s(|S|-1)$, and $\nu_e=m_e-s=0$. So

$$v=\frac{1}{\Gamma(1)^2}\int_{a_1+a_2+a_3+a_4=1}\prod_{e=1}^{4}\Gamma(a_e)^2,$$

a fibre integral of dimension 3.

Merging the pairs. Put $c=a_1+a_2$. Corollary 4.7 with the entries $a=b=0$, $c=d=c$ and the variable a_1 merges the pair $\{1,2\}$,

$$\frac{1}{2\pi i}\int\Gamma(a_1)^2\,\Gamma(c-a_1)^2\,da_1=\Gamma\begin{bmatrix}c,\ c,\ c,\ c\\ 2c\end{bmatrix},$$

and the same with the total $1-c$ merges $\{3,4\}$. One share is left:

$$v=\frac{1}{2\pi i}\int_{(\frac12)}\Gamma\begin{bmatrix}c,\ c,\ c,\ c\\ 2c\end{bmatrix}\,\Gamma\begin{bmatrix}1-c,\ 1-c,\ 1-c,\ 1-c\\ 2-2c\end{bmatrix}\,dc.$$

The integrand. By the reflection and the shift (Proposition 1.3(iii),(v)), $\Gamma(c)^4\Gamma(1-c)^4=\pi^4/\sin^4\pi c$ and $\Gamma(2c)\Gamma(2-2c)=(1-2c)\,\Gamma(2c)\Gamma(1-2c)=(1-2c)\,\pi/\sin 2\pi c$, so the integrand is

$$w(c)=\frac{\pi^4}{\sin^4\pi c}\cdot\frac{\sin 2\pi c}{(1-2c)\,\pi}=\frac{2\pi^3\cos\pi c}{(1-2c)\sin^3\pi c}.$$

At $c=\frac12$ the zero of $\cos\pi c$ cancels that of $1-2c$, so the poles of w are the integers. The factor $2\pi^3\cos\pi c/\sin^3\pi c$ is $-\partial_c\Gamma\big[c,\ c,\ 1-c,\ 1-c\big]=2\sum_{m\in\mathbb{Z}}(c+m)^{-3}$ (Lemma 5.16), of period one, and at $c=m+\varepsilon$

$$\frac{2\pi^3\cos\pi\varepsilon}{\sin^3\pi\varepsilon}=\frac{2}{\varepsilon^3}-\frac{2\pi^4}{15}\,\varepsilon+O(\varepsilon^3):$$

no terms in ε^{-2}, ε^{-1} or ε^0.

The closing. At $c=N+\frac12+iy$, $|\cos\pi c|=|\sinh\pi y|$ and $|\sin\pi c|=\cosh\pi y$, so $|w(c)|\le 4\pi^3e^{-2\pi|y|}/(2N)$: the integrals over the lines $\operatorname{Re}c=N+\frac12$ tend to zero, and so do those over the horizontal segments $\operatorname{Im}c=\pm Y$ as $Y\to\infty$. The line closes to the right (Theorem 4.5) on the triple poles at the integers $m\ge1$, with the residues

$$\operatorname*{Res}_{c=m}w=2\,[\varepsilon^2]\,\frac{1}{1-2m-2\varepsilon}=\frac{2\cdot4}{(1-2m)^3}=-\frac{8}{(2m-1)^3},$$

and closing to the right takes minus their sum:

$$v=\sum_{m\ge1}\frac{8}{(2m-1)^3}=\sum_{x\in\frac12+\mathbb{Z},\ x>0}x^{-3}=(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,\infty))$$

(Definition 5.2).

The coset relation. Theorem 5.12(i) at $q=2$ and $b=0$, with the kernel x^{-3} and the cut 0, assembles $\frac12\mathbb{Z}$ from its two cosets, the rescaled kernel being $(x/2)^{-3}=8x^{-3}$:

$$(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))+(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,\infty))=8\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)).$$

So $v = (\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,\infty)) = 7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$, which is $8.41439832211715999 78\ldots$ to 19 places; the receipt evaluates the contour integral by quadrature as a check. The coset $\frac12+\mathbb{Z}$ is the doubled share $2c$ of a merged pair, the lower entry of $\Gamma_{\!4\atop 1}\!\begin{bmatrix} c,\ c,\ c,\ c \\ & 2c & \end{bmatrix}$: the word has one lower Gamma of slope 2 and one of slope -2, which pair off (Proposition 43.2), and its rational factor $(1-2c)^{-1}$ has its pole on that coset. □

Exercise 54.8 (The law, the low-end relation and the rows)**.** (i) With $\vartheta = y\frac{d}{dy}$, compute the operators $\mathbf{R}_0,\ldots,\mathbf{R}_5$ of Theorem 42.12 for $n=4$, and from them the law of the values, $\sum_{k=0}^{2} c_{4,k}(s)\,P(s+k)=0$.

(ii) Give the closings $\mathsf{C}_j(1)$ for $j\le 8$, and check the law read at $k=-j$ on them.

(iii) Give the symbol, its roots and the native gauges they belong to.

(iv) Write the low-end relation.

(v) Write the rows $P(k)=a_kv-b_k$ for $k\le 6$ (Definition 36.5), and the value span of the ray.

Solution. Receipt: `ex24b_law.py`.

(i) *One mark.* At the strength s the masses are $s\mathbf{1}$ and the exponents (s,s), and Corollary 18.24, as in Exercise 54.7, gives the share side in its first form,

$$\Gamma(s)^2P(s)=\int_0^\infty y^{s-1}\,\mathsf{g}(y)^4\,dy,\qquad \mathsf{g}(y)=\mathsf{G}_{0;(1,-1)}(1,y),\quad \operatorname{Re}s>0.$$

The Gramma g satisfies $\vartheta^2\mathsf{g}=y\,\mathsf{g}$. Write $\mathsf{g}_\nu=\mathsf{G}_{\nu;(1,-1)}(1,y)$. The ladder (Theorem 2.4(i)) in the coefficient y of the exponent -1 gives $\vartheta\mathsf{g}_\nu=-y\,\mathsf{g}_{\nu-1}$, so $\vartheta^2\mathsf{g}_0=-y\,\mathsf{g}_{-1}+y^2\mathsf{g}_{-2}$; the exchange relation (Theorem 2.4(ii)) at $\nu=-1$ reads $-\mathsf{g}_{-1}=\mathsf{g}_0-y\,\mathsf{g}_{-2}$, and substituting $y\,\mathsf{g}_{-2}=\mathsf{g}_0+\mathsf{g}_{-1}$ gives $\vartheta^2\mathsf{g}_0=y\,\mathsf{g}_0$.

The operators. Theorem 42.12(i) at $n=4$ has $\mathbf{R}_0=1$, $\mathbf{R}_1=\vartheta$ and $\mathbf{R}_{i+1}=\vartheta\mathbf{R}_i-i(5-i)\,y\,\mathbf{R}_{i-1}$, with the coefficients $i(5-i)=4,6,6,4$; an operator is written $\sum_k y^kq(\vartheta)$, and $\vartheta\,y^kq(\vartheta)=y^k(\vartheta+k)\,q(\vartheta)$. So

$$\begin{aligned}
\mathbf{R}_2&=\vartheta^2-4y,\\
\mathbf{R}_3&=\vartheta^3-2y(5\vartheta+2),\\
\mathbf{R}_4&=\vartheta^4-2y(8\vartheta^2+7\vartheta+2)+24y^2,\\
\mathbf{R}_5&=\vartheta^5-2y(2\vartheta+1)(5\vartheta^2+5\vartheta+2)+64y^2(\vartheta+1),
\end{aligned}$$

and $\mathbf{Q}_4=\mathbf{R}_5$ annihilates every product of four solutions of $\vartheta^2u=yu$, g^4 among them; the receipt checks it on the basis $u^{4-i}(\vartheta u)^i$. The leading coefficients $1,-20,64$ of $q_{4,0},q_{4,1},q_{4,2}$ are those of $\xi(\xi^2-16\eta)(\xi^2-4\eta)=\xi^5-20\eta\xi^3+64\eta^2\xi$, as Theorem 42.12(i) says.

The law. Integrated against y^{s-1}, a term $y^kq(\vartheta)$ becomes $q(-s-k)$ times the transform at $s+k$: integration by parts turns ϑ into $-s$, the boundary terms vanishing because g is $O(|\log y|)$ at 0 (Lemma 20.29(i)) and at most $\sqrt{\pi}\,y^{-1/4}e^{-2\sqrt{y}}$ for $y\ge1$ (Lemma 20.29(ii)). With $\Gamma(s+k)^2=\Gamma(s)^2(s)_k^2$ and a division by $\Gamma(s)^2s^2$ this is Theorem 42.12(ii):

$$c_{4,0}(s)=-s^3,\qquad c_{4,1}(s)=q_{4,1}(-s-1)=2(2s+1)(5s^2+5s+2),$$
$$c_{4,2}(s)=q_{4,2}(-s-2)\,(s+1)^2=-64(s+1)^3,$$

$$-s^3P(s)+2(2s+1)(5s^2+5s+2)\,P(s+1)-64(s+1)^3P(s+2)=0$$

identically in s. At $s=1$ the coefficients are -1, 72, -512.

(ii) *The closings.* By Corollary 39.36 $\mathsf{C}_j(1)$ is the constant term of $f^{-j}=K(\alpha)^jK(\alpha^{-1})^j$; the multinomial expansions of the two factors pair the monomial α^v with α^{-v}, so

$$\mathsf{C}_j(1)=\sum_{|v|=j}\binom{j}{v}^2=1,\ 4,\ 28,\ 256,\ 2716,\ 31504,\ 387136,\ 4951552,\ 65218204\qquad(j=0,\dots,8).$$

The law read at $k=-j$ (Corollary 39.36, Theorem 42.12(iii)) is $\sum_{i\le\min(2,j)}c_{4,i}(-j)\,\mathsf{C}_{j-i}(1)=0$: at $j=1$, $1\cdot4+(-4)\cdot1=0$; at $j=2$, $8\cdot28+(-72)\cdot4+64\cdot1=0$; the receipt checks it for $j\le40$, and also that $\mathbf{Q}_4$ annihilates $\mathsf{h}^4=\sum_j\mathsf{C}_j(1)\,y^j/j!^2$, $\mathsf{h}(y)=\sum_m y^m/m!^2$, through y^{40}.

(iii) *The symbol.* The coefficients of s^3 in $c_{4,0},c_{4,1},c_{4,2}$ are $-1,20,-64$, so the symbol (Corollary 38.7) is

$$\chi_4(\lambda)=-1+20\lambda-64\lambda^2=-(1-4\lambda)(1-16\lambda),$$

with the roots $\frac{1}{16}$ and $\frac14$. By Proposition 42.9(ii) the native gauges of the ray are the signs η with $K(\eta)\neq0$, of native value $K(\eta)^{-2}$: $\eta=\mathbf{1}$, with $K=4$ and the native value $\frac{1}{16}=f(\alpha^\star)$, $\alpha^\star=\mathbf{1}$ being the native gauge of the direction (Theorem 38.14); and the signs with one or three marks at -1, with $K=\pm2$ and the native value $\frac14$. The signs with two marks at -1 have $K=0$ and lie off X_F.

(iv) *The low-end relation.* By Corollary 39.38(ii), with $[s^3]c_{4,0}=-1$, $\mathsf{L}_0=V_1=24$, $c_{4,1}(0)=4$ and $c_{4,2}(0)=-64$,

$$-24+4P(1)-64P(2)=0,\qquad P(2)=\frac{P(1)-6}{16}.$$

(v) *The rows.* $P(1)=v$ and $P(2)=\frac{1}{16}v-\frac38$, and the law at $s=k\ge1$, whose last coefficient $c_{4,2}(k)$ does not vanish, gives $P(k+2)=-\big(c_{4,0}(k)P(k)+c_{4,1}(k)P(k+1)\big)/c_{4,2}(k)$; at $k=1$, $P(3)=\big(72P(2)-P(1)\big)/512=\frac{7}{1024}v-\frac{27}{512}$. The rows $(a_k;b_k)$:

k	1	2	3	4	5	6
a_k	1	$\frac{1}{16}$	$\frac{7}{1024}$	$\frac{1}{1024}$	$\frac{679}{4194304}$	$\frac{1969}{67108864}$
b_k	0	$\frac38$	$\frac{27}{512}$	$\frac{37}{4608}$	$\frac{25555}{18874368}$	$\frac{9304913}{37748736000}$

So every value lies in $\mathbb{Q}+\mathbb{Q}\,v$, $v=(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,\infty))$ (Exercise 54.7), and this is the value span of the ray (Corollary 42.15(i), with $h=2$): the order $h=2$ leaves one value free after the low-end relation. As renderings, $P(2)=0.15089989513232249986\dots$, $P(3)=0.0047859260300977734224\dots$ and $P(4)=0.00018767197255365017146\dots$; the receipt checks $P(2)$ against the quadrature of $\int_0^\infty y\,\mathsf{g}(y)^4dy$. □

Exercise 54.9 (The row at every step)**.** For $n\ge0$ put $p_l=l+\frac12$ and $j=n-l$ for $0\le l\le n$,

$$c_l=\binom{2l}{l}\binom{2j}{j},\qquad S_l=\frac{c_l}{\binom{n}{l}}=\frac{(2l)!\,(2j)!}{l!\,j!\,n!},\qquad w_l=S_l^2c_l,\qquad F(\sigma)=\binom{\sigma-1}{n}^2,$$

$F[\sigma,p]=\big(F(\sigma)-F(p)\big)/(\sigma-p)$, and for a polynomial g

$$\mathcal{J}[g]=\frac{1}{2\pi i}\int_{(\frac12)}g(\sigma)\sum_{m\in\mathbb{Z}}\frac{d\sigma}{(\sigma+m)^3}.$$

Show that

$$256^n\,P(n+1)=\sum_{l=0}^{n}w_l\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((l,\infty))-16^n\sum_{l=0}^{n}c_l\,\mathcal{J}\big[F[\,\cdot\,,p_l]\big],$$

evaluate $\mathcal{J}$ on the binomial polynomials $\binom{\sigma}{i}$, and read the rows of $P(2)$ and $P(3)$ off the formula.

Solution. Receipt: `ex24c_row.py`.

(a) *The word.* At the strength $k = n+1$ the share side of Exercise 54.7, with the shares of total k and the pairs merged by Corollary 4.7 at the totals σ and $k-\sigma$, is

$$P(k) = \frac{1}{\Gamma(k)^2}\,\frac{1}{2\pi i}\int \frac{\Gamma(\sigma)^4\,\Gamma(k-\sigma)^4}{\Gamma(2\sigma)\,\Gamma(2k-2\sigma)}\,d\sigma \qquad (0 < \operatorname{Re}\sigma < k).$$

With $\Gamma(k-\sigma) = (1-\sigma)_n\Gamma(1-\sigma)$ and $\Gamma(2k-2\sigma) = (2-2\sigma)_{2n}(1-2\sigma)\Gamma(1-2\sigma)$ (Proposition 1.3(iii)), the reflections of Exercise 54.7 give the factor $2\pi^3\cos\pi\sigma/\sin^3\pi\sigma = 2\sum_m(\sigma+m)^{-3}$ against $(1-\sigma)_n^4/\big((1-2\sigma)(2-2\sigma)_{2n}\big)$. Splitting $(2-2\sigma)_{2n}$ into its factors $2(1-\sigma+t)$ and $2(\frac{3}{2}-\sigma+t)$, $0 \le t < n$, gives $(1-2\sigma)(2-2\sigma)_{2n} = 2\cdot 4^n(\frac{1}{2}-\sigma)_{n+1}(1-\sigma)_n$, so

$$P(n+1) = \frac{1}{4^n\,n!^2}\,\frac{1}{2\pi i}\int \rho(\sigma)\sum_m \frac{d\sigma}{(\sigma+m)^3}, \qquad \rho(\sigma) = \frac{(1-\sigma)_n^3}{(\frac{1}{2}-\sigma)_{n+1}}.$$

The triple poles of the kernel at $1,\dots,n$ meet the triple zeros of ρ, and the simple poles of ρ at the p_l meet the zeros of the kernel, so the integrand is regular on $0 < \operatorname{Re}\sigma < k$ and the line may be $\operatorname{Re}\sigma = \frac{1}{2}$.

(b) *Partial fractions.* With $\Omega(\sigma) = \prod_{i=1}^n(\sigma-i) = n!\binom{\sigma-1}{n}$, $(1-\sigma)_n = (-1)^n\Omega$ and $(\frac{1}{2}-\sigma)_{n+1} = (-1)^{n+1}\prod_{i=0}^n(\sigma-p_i)$, so $\rho/\Omega^2 = -\Omega/\prod_i(\sigma-p_i)$, whose residue at p_l is $-\Omega(p_l)/\prod_{i\ne l}(l-i)$, with $\prod_{i\ne l}(l-i) = (-1)^j l!\,j!$ and

$$\Omega(p_l) = \prod_{t=0}^{l-1}\big(t+\tfrac{1}{2}\big)\prod_{t=1}^{j}\big(\tfrac{1}{2}-t\big) = \frac{(-1)^j(2l-1)!!\,(2j-1)!!}{2^n}.$$

As $(2l-1)!!/l! = \binom{2l}{l}/2^l$, the residue is $-c_l/4^n$:

$$\frac{\rho}{\Omega^2} = -\frac{1}{4^n}\sum_{l=0}^{n}\frac{c_l}{\sigma-p_l}.$$

Multiplying by $\Omega^2 = n!^2F$ and writing $\Omega(\sigma)^2 = \Omega(p_l)^2 + (\sigma-p_l)\,n!^2F[\sigma,p_l]$ splits ρ into a polynomial and its poles,

$$\rho = \mathcal{P} + \sum_{l=0}^{n}\frac{r_l}{\sigma-p_l}, \qquad \mathcal{P} = -\frac{n!^2}{4^n}\sum_l c_l\,F[\sigma,p_l], \qquad r_l = -\frac{c_l\,\Omega(p_l)^2}{4^n} = -\frac{n!^2\,w_l}{64^n},$$

the last because $(2l-1)!!\,(2j-1)!! = S_l\,n!/2^n$. The receipt checks the partial fractions and the r_l for $n \le 3$.

(c) *The pole terms.* The kernel is $\pi^3\cos\pi\sigma/\sin^3\pi\sigma$, with the principal part $(\sigma-i)^{-3}$ and no terms of orders $-2,-1,0$ at every integer i (Exercise 54.7), so the residue of $(\sigma-p_l)^{-1}$ times the kernel at i is $\frac{1}{2}\partial_\sigma^2(\sigma-p_l)^{-1}|_{\sigma=i} = (i-p_l)^{-3}$; at p_l the kernel vanishes. On the lines $\operatorname{Re}\sigma = N+\frac{1}{2}$ the integrand is $O(N^{-1}e^{-2\pi|\operatorname{Im}\sigma|})$, so the line closes to the right (Theorem 4.5):

$$\frac{1}{2\pi i}\int_{(\frac{1}{2})}\frac{1}{\sigma-p_l}\sum_m\frac{d\sigma}{(\sigma+m)^3} = -\sum_{i\ge 1}\frac{1}{(i-p_l)^3} = -(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac{1}{2}+\mathbb{Z}})((l,\infty)),$$

the terms $i \le l$, at the negative points $i-p_l$, cancelling the head $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac{1}{2}+\mathbb{Z}})((0,l])$ of the terms at the positive points (Proposition 5.3). The polynomial part gives $\mathcal{J}[\mathcal{P}]$.

(d) *Assembling.* By (a) to (c),

$$P(n+1)=\frac{1}{4^n n!^2}\Big(-\frac{n!^2}{4^n}\sum_l c_l\,\mathcal{J}\big[F[\cdot,p_l]\big]+\frac{n!^2}{64^n}\sum_l w_l\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((l,\infty))\Big),$$

which is the stated formula after multiplication by 256^n. With $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((l,\infty))=v-(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,l])$ the row of $P(n+1)$ is

$$a_{n+1}=\frac{1}{256^n}\sum_{l=0}^{n}w_l,\qquad b_{n+1}=\frac{1}{256^n}\Big(\sum_{l=0}^{n}w_l\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,l])+16^n\sum_{l=0}^{n}c_l\,\mathcal{J}\big[F[\cdot,p_l]\big]\Big).$$

(e) *The functional $\mathcal{J}$.* By Lemma 5.16, $\sum_m(\sigma+m)^{-3}=-\frac12\partial_\sigma\Gamma_4^{\,0}\big[\sigma,\ \sigma,\ 1-\sigma,\ 1-\sigma\big]$, and on the line the stacked Gamma is $2\pi\,p_{\mathrm{crit}}(y)$, $\sigma=\frac12+iy$, decaying like $e^{-2\pi|y|}$ (Definition 36.1). Integrating by parts,

$$\mathcal{J}[g]=\frac12\,\mathbb{E}\big[g'(X)\big],\qquad X=\tfrac12+iY,\quad Y\sim\mathbb{P}_{\mathrm{crit}}.$$

By Theorem 36.2(iii), $\mathbb{E}[e^{tX}]=te^t/(e^t-1)$ for $|t|<2\pi$, so $\mathbb{E}[X^m]=1,\frac12,\frac16,0,-\frac{1}{30},0,\frac{1}{42},0,-\frac{1}{30}$ for $m=0,\dots,8$, and at $t=\log(1+z)$, $\mathbb{E}[(1+z)^X]=(1+z)\log(1+z)/z$. Since $\sum_i\binom{\sigma}{i}z^i=(1+z)^\sigma$, whose derivative in σ is $\log(1+z)\,(1+z)^\sigma$,

$$\sum_{i\ge0}\mathcal{J}\Big[\binom{\sigma}{i}\Big]z^i=\frac12\log(1+z)\,\mathbb{E}\big[(1+z)^X\big]=\frac{(1+z)\log^2(1+z)}{2z}.$$

With $\log^2(1+z)=2\sum_{m\ge2}(-1)^m(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,m-1])\,z^m/m$, the head $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,m])=\sum_{r=1}^m\frac1r$ (Definition 5.2), the coefficients are

$$\lambda_0=0,\qquad \lambda_i=\mathcal{J}\Big[\binom{\sigma}{i}\Big]=(-1)^i\,\frac{(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,i-1])-1}{i(i+1)}\quad(i\ge1),$$

that is $0,\frac12,0,-\frac{1}{24},\frac{1}{24},-\frac{13}{360},\frac{11}{360},-\frac{29}{1120},\frac{223}{10080}$ for $i=0,\dots,8$; the receipt checks them against the moments for $i<40$. A polynomial written in the binomial basis, $g=\sum_i(\Delta^i g)(0)\binom{\sigma}{i}$, has $\mathcal{J}[g]=\sum_i(\Delta^i g)(0)\,\lambda_i$.

(f) *The first steps.* At $n=1$: $c_0=c_1=2$, $S_0=S_1=2$, $w_0=w_1=8$; $F(\sigma)=(\sigma-1)^2$, $F[\sigma,p]=\sigma+p-2$, so $F[\sigma,\frac12]=\sigma-\frac32$ and $F[\sigma,\frac32]=\sigma-\frac12$, each with $\mathcal{J}=\frac12$; with $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,1])=8$,

$$256\,P(2)=16v-8\cdot8-16\Big(2\cdot\frac12+2\cdot\frac12\Big)=16v-96,\qquad P(2)=\frac{1}{16}v-\frac38.$$

At $n=2$: $(c_0,c_1,c_2)=(6,4,6)$, $(S_0,S_1,S_2)=(6,2,6)$, $(w_0,w_1,w_2)=(216,16,216)$, and

$$\begin{aligned}F[\sigma,\tfrac12]&=\tfrac14\sigma^3-\tfrac{11}{8}\sigma^2+\tfrac{41}{16}\sigma-\tfrac{55}{32},&\mathcal{J}&=\tfrac{21}{32},\\ F[\sigma,\tfrac32]&=\tfrac14\sigma^3-\tfrac{9}{8}\sigma^2+\tfrac{25}{16}\sigma-\tfrac{21}{32},&\mathcal{J}&=\tfrac{9}{32},\\ F[\sigma,\tfrac52]&=\tfrac14\sigma^3-\tfrac{7}{8}\sigma^2+\tfrac{17}{16}\sigma-\tfrac{11}{32},&\mathcal{J}&=\tfrac{5}{32},\end{aligned}$$

for instance $\mathcal{J}\big[F[\cdot,\frac12]\big]=\frac12\mathbb{E}\big[\frac34X^2-\frac{11}{4}X+\frac{41}{16}\big]=\frac12\big(\frac18-\frac{11}{8}+\frac{41}{16}\big)=\frac{21}{32}$. With the heads $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,1])=8$ and $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,2])=8+\frac{8}{27}$,

$$256^2P(3)=448\,v-\Big(16\cdot8+216\cdot\frac{224}{27}\Big)-256\Big(6\cdot\frac{21}{32}+4\cdot\frac{9}{32}+6\cdot\frac{5}{32}\Big)=448\,v-1920-1536,$$

so $P(3) = \frac{7}{1024}v - \frac{27}{512}$. Both rows are those of Exercise 54.8.

So the row of $P(n+1)$ at every step is $a_{n+1} = 256^{-n}\sum_l w_l$ and b_{n+1} as in (d), with $\mathcal{J}$ read through the λ_i. For $n = 0,1,2,3$ the sums are $\sum_l w_l = 1, 16, 448, 16384$, $256^n b_{n+1} = 0, 96, 3456, \frac{1212416}{9}$ and $\sum_l c_l \mathcal{J}[F[\cdot, p_l]] = 0, 2, 6, \frac{853}{54}$; the receipt checks that the formula reproduces the rows of the law for $n \le 40$. □

Exercise 54.10 (The coefficient of the coordinate is a closing)**.** Show that $a_k = \mathsf{C}_{k-1}(1)/64^{k-1}$ for every $k \ge 1$, and give the denominator of a_k:

(i) from the law of Exercise 54.8, by Theorem 43.8;

(ii) directly from the row of Exercise 54.9, by a telescoping identity in the summation index.

Solution. Receipt: `ex24d_closing.py`.

(i) *The law is reflexive.* With $h = 2$, Definition 43.7 asks for $c_{4,2-i}(-k-1) = \gamma\lambda^i c_{4,i}(k)$, $i = 0,1,2$. Here

$$c_{4,2}(-k-1) = 64k^3 = -64\,c_{4,0}(k), \qquad c_{4,0}(-k-1) = (k+1)^3,$$
$$c_{4,1}(-k-1) = -2(2k+1)(5k^2+5k+2) = -c_{4,1}(k),$$

so $\gamma = -64$, $\gamma\lambda = -1$ gives the ratio $\lambda = \frac{1}{64}$, and $\gamma\lambda^2 c_{4,2}(k) = -\frac{64}{4096}\cdot(-64)(k+1)^3 = (k+1)^3$ checks the third. The ray has the origin 0, every letter exponent positive and positive walls, as Proposition 43.6 asks. By Theorem 43.8(i), $y_k = 64^{1-k}\mathsf{C}_{k-1}(1)$ solves the law on $k \ge 1$ with the low-end coefficient $-\big(c_{4,1}(0)y_1 + c_{4,2}(0)y_2\big) = -\big(4\cdot 1 - 64\cdot\frac{4}{64}\big) = 0$, and since $c_{4,2}(k) \ne 0$ for $k \ge 0$, Theorem 43.8(ii) gives

$$P(k) = \frac{\mathsf{C}_{k-1}(1)}{64^{k-1}}\,P(1) + r_k, \qquad a_k = \frac{\mathsf{C}_{k-1}(1)}{64^{k-1}}.$$

By Theorem 43.8(iii), with $\lambda = \frac{1}{64}$, the denominator of a_k is $64^{k-1}/\gcd\big(64^{k-1}, \mathsf{C}_{k-1}(1)\big)$:

k	1	2	3	4	5	6	7	8
$\mathsf{C}_{k-1}(1)$	1	4	28	256	2716	31504	387136	4951552
$v_2\big(\mathsf{C}_{k-1}(1)\big)$	0	2	2	8	2	4	6	9
$\log_2 \mathrm{den}(a_k)$	0	4	10	10	22	26	30	33

with v_2 the exponent of 2.

(ii) *The closings across the pairs.* Split $f^{-1} = (X+Y)(X'+Y')$ with $X = \alpha_1 + \alpha_2$, $X' = \alpha_1^{-1} + \alpha_2^{-1}$, and Y, Y' the same on $\{3,4\}$. In $(X+Y)^n(X'+Y')^n = \sum_{l,l'}\binom{n}{l}\binom{n}{l'}X^l Y^{n-l} X'^{l'} Y'^{n-l'}$ a term has a constant term in α_1, α_2 only if $l = l'$, X^l and $X'^{l'}$ being homogeneous of degrees l and $-l'$, and $\mathrm{CT}\,\big((XX')^l\big) = \sum_i \binom{l}{i}^2 = \binom{2l}{l}$. So

$$\mathsf{C}_n(1) = \sum_{l=0}^{n}\binom{n}{l}^2\binom{2l}{l}\binom{2j}{j} =: U(n), \qquad j = n-l.$$

Put $T(n) = 4^{-n}\sum_l w_l$, so that $a_{n+1} = 4^n T(n)/256^n$ by Exercise 54.9. It remains to show $T = U$.

The telescoping identities. Both T and U satisfy

$$(n+2)^3 X_{n+2} - 2(2n+3)(5n^2+15n+12)\,X_{n+1} + 64(n+1)^3 X_n = 0 \qquad (n \ge 0),$$

which is the law of the closings of Exercise 54.8(ii) at $j = n+2$: $c_{4,0}(-n-2) = (n+2)^3$, $c_{4,1}(-n-2) = -2(2n+3)(5n^2+15n+12)$, $c_{4,2}(-n-2) = 64(n+1)^3$. Write $t(n,l)$ for the

summand of either sum, $t_T(n,l) = 4^{-n}S_l^2 c_l$ and $t_U(n,l) = \binom{n}{l}^2 c_l$, zero outside $0 \le l \le n$. Their ratios are rational:

$$\frac{t_T(n,l+1)}{t_T(n,l)} = \frac{(2l+1)^3\, j}{(l+1)(2j-1)^3}, \qquad \frac{t_T(n+1,l)}{t_T(n,l)} = \frac{2(2j+1)^3}{(j+1)(n+1)^2},$$
$$\frac{t_U(n,l+1)}{t_U(n,l)} = \frac{j^3(2l+1)}{(l+1)^3(2j-1)}, \qquad \frac{t_U(n+1,l)}{t_U(n,l)} = \frac{2(n+1)^2(2j+1)}{(j+1)^3}.$$

With $G = Rt$ and the rational functions

$$R_T = \frac{4l\,(2j+1)^3\,\kappa_T}{(n+1)^2(j+1)(j+2)}, \qquad R_U = -\frac{4(n+1)^2\,l^3\,(2j+1)\,\kappa_U}{(j+1)^3(j+2)^3},$$

$$\kappa_T = 12j^3 + 10lj^2 + 2l^2j + 59j^2 + 33lj + 4l^2 + 94j + 26l + 49,$$
$$\kappa_U = 12j^3 + 10lj^2 + 2l^2j + 62j^2 + 35lj + 3l^2 + 104j + 30l + 56,$$

each summand satisfies, for $0 \le l \le n-1$,

$$64(n+1)^3 t(n,l) - 2(2n+3)(5n^2+15n+12)\,t(n+1,l) + (n+2)^3 t(n+2,l) = G(n,l+1) - G(n,l).$$

Divided by $t(n,l)$ and written with the ratios this is an identity of rational functions of (n,l); cleared of denominators it is an identity of polynomials, which the receipt verifies coefficient by coefficient for both T and U. Summing it over $0 \le l \le n-1$, with $G(n,0) = 0$ (the factor l), leaves $G(n,n)$, and the full sum over l of the left side is $G(n,n)$ plus the left side at $l = n, n+1, n+2$, where only the summands with $l \le n+1$ at $n+1$ and $l \le n+2$ at $n+2$ survive. Divided by $t(n,n)$, with $t(n+1,n)/t(n,n)$, $t(n+1,n+1)/t(n,n)$, $t(n+2,n)/t(n,n)$, $t(n+2,n+1)/t(n,n)$ and $t(n+2,n+2)/t(n,n)$ read off the ratios, this boundary sum is a rational function of n that vanishes identically (receipt). So both sums satisfy the recurrence; $T(0) = U(0) = 1$, $T(1) = \frac{1}{4}(8+8) = 4 = U(1)$, and the leading coefficient $(n+2)^3$ does not vanish, so $T = U$.

Hence $\sum_l w_l = 4^n \mathsf{C}_n(1)$ and $a_{n+1} = 4^n \mathsf{C}_n(1)/256^n = \mathsf{C}_n(1)/64^n$, as in (i). The coefficient of the coordinate v in $P(k)$ is the closing $\mathsf{C}_{k-1}(1)$ over 64^{k-1}, with no lattice sum: $64^{k-1}a_k \in \mathbb{Z}$, and the denominator of a_k is $64^{k-1}/\gcd\big(64^{k-1}, \mathsf{C}_{k-1}(1)\big)$. □

Exercise 54.11 (The clearing)**.** Show that for every $k \ge 1$ the part of the denominator of b_k prime to 2 divides d_{k-1}^3, and that $256^{k-1}d_{k-1}^3\, b_k \in \mathbb{Z}$; so $256^{k-1}d_{k-1}^3$ clears the row of $P(k)$. Compare it with the bound of the frame.

Solution. Receipt: `ex24e_clearing.py`.

Write $n = k-1$. By Exercise 54.9(d), $256^n b_{n+1}$ is the sum of the heads and the moments,

$$\sum_l w_l\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac{1}{2}+\mathbb{Z}})((0,l)) \qquad \text{and} \qquad 16^n \sum_l c_l\,\mathcal{J}\big[F[\cdot,p_l]\big];$$

and by Exercise 54.10 $64^n a_{n+1} = \mathsf{C}_n(1) \in \mathbb{Z}$. Two facts from outside the handbook are used: Legendre's formula, $v_q(m!) = \sum_{t\ge1}\lfloor m/q^t\rfloor$ for a prime q, and Kummer's theorem, that $v_q\binom{a+b}{a}$ is the number of carries when a and b are added in base q; v_q is the exponent of q.

The integers. $S_l \in \mathbb{Z}$: by Legendre's formula, $v_q(S_l) = \sum_{t\ge1}\big(\lfloor 2l/q^t\rfloor + \lfloor 2j/q^t\rfloor - \lfloor l/q^t\rfloor - \lfloor j/q^t\rfloor - \lfloor n/q^t\rfloor\big)$, and every term is nonnegative by $\lfloor 2x\rfloor + \lfloor 2y\rfloor \ge \lfloor x\rfloor + \lfloor y\rfloor + \lfloor x+y\rfloor$ (with $x = a+\alpha$, $y = b+\beta$, $0 \le \alpha, \beta < 1$, it reads $\lfloor 2\alpha\rfloor + \lfloor 2\beta\rfloor \ge \lfloor \alpha+\beta\rfloor$, true since $\alpha+\beta \ge 1$ forces $\max(\alpha,\beta) \ge \frac{1}{2}$). So $w_l = S_l^2 c_l \in \mathbb{Z}$.

Fix an odd prime q and $e \ge 1$ with $q^{e-1} \le n < q^e$, so that $v_q(d_n^3) = 3(e-1)$; it suffices that both sums have $v_q \ge -3(e-1)$.

The heads. $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac12+\mathbb{Z}})((0,l]) = 8\sum_{i=1}^{l}(2i-1)^{-3}$, and $2l-1 < 2n < 2q^e$, so the only odd number up to $2l-1$ with $v_q \ge e$ is q^e, when $q^e \le 2l-1$. In that case, at the level q^e of Legendre's formula, $\lfloor l/q^e\rfloor = \lfloor j/q^e\rfloor = \lfloor n/q^e\rfloor = 0$ and $\lfloor 2l/q^e\rfloor = 1$, so $v_q(S_l) \ge 1$ and $v_q\binom{2l}{l} \ge 1$, the other levels contributing ≥ 0; then $v_q(w_l) \ge 3$, which pays for $(q^e)^{-3}$. Otherwise the head already has $v_q \ge -3(e-1)$.

The moments. Vandermonde's identity twice, $\binom{\sigma}{m} = \sum_t \binom{\sigma-p}{t}\binom{p}{m-t}$ and $\binom{\sigma-p-1}{t-1} = \sum_i \binom{\sigma}{i}\binom{-p-1}{t-1-i}$, with $\binom{\sigma-p}{t} = \frac{\sigma-p}{t}\binom{\sigma-p-1}{t-1}$, gives the binomial coefficients of the divided difference,

$$\big(\Delta^i F[\cdot,p]\big)(0) = \sum_m f_m \sum_{t=i+1}^{m} \frac{1}{t}\binom{p}{m-t}\binom{-p-1}{t-1-i}, \qquad F = \sum_m f_m\binom{\sigma}{m}.$$

Here $f_m = \sum_{i,i'\le n}(-1)^{i+i'}\binom{m}{i}\binom{i}{m-i'}$, from $\binom{\sigma-1}{n} = \sum_{i\le n}(-1)^{n-i}\binom{\sigma}{i}$ and $\binom{\sigma}{i}\binom{\sigma}{i'} = \sum_m \binom{m}{i}\binom{i}{m-i'}\binom{\sigma}{m}$; so $f_m \in \mathbb{Z}$, and $q \mid f_m$ for $m \ge q^e$: a nonzero term has $i < q^e$ and $m-i \le i' < q^e$, and adding i and $m-i$ in base q carries into the place q^e, so $q \mid \binom{m}{i}$ (Kummer's theorem). At $p = p_l$, a q-adic integer, the binomials of p and of $-p-1$ are q-integral. Since $t \le 2n < 2q^e$, the only t with $v_q(t) \ge e$ is $t = q^e$, where $m \ge q^e$ and $q \mid f_m$. So $v_q\big((\Delta^i F[\cdot,p_l])(0)\big) \ge 1-e$ for every i, and $\ge 2-e$ for $i \ge q^e$, where every t and m exceed q^e.

For $1 \le i \le 2n-1$: $v_q(\lambda_i) \ge 2-2e$ for $i < q^e$ and $v_q(\lambda_i) \ge 1-2e$ for $i \ge q^e$. The heads of the counting input at index one have $v_q\big((\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,m])\big) \ge 1-e$ for $m < q^e$ and $\ge -e$ for $q^e \le m < 2q^e$, while

$$v_q\big((\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,q^e-1])\big) \ge 2-e :$$

grouping the $r < q^e$ by $v_q(r) = s$, $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,q^e-1]) = \sum_{s<e} q^{-s}\sum_{r'<q^{e-s},\ q\nmid r'}\frac{1}{r'}$, and $\sum_{r'<q^a,\ q\nmid r'}\frac{1}{r'}$ has $v_q \ge a$, pairing r' with $q^a - r'$, $\frac{1}{r'} + \frac{1}{q^a-r'} = \frac{q^a}{r'(q^a-r')}$; each term has $v_q \ge e-2s \ge 2-e$. The integers i and $i+1$ are coprime and below $2q^e$, so $v_q\big(i(i+1)\big) \le e-1$ unless $q^e \in \{i, i+1\}$, where it is e. For $i < q^e-1$ this gives $v_q(\lambda_i) \ge (1-e)-(e-1)$. At $i = q^e-1$, $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,q^e-2]) - 1 = (\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,q^e-1]) - \frac{q^e}{q^e-1}$ has $v_q \ge \min(2-e,e)$, so $v_q(\lambda_i) \ge \min(2-e,e) - e \ge 2-2e$. At $i = q^e$, $(\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,q^e-1]) - 1$ has $v_q \ge \min(2-e,0)$, so $v_q(\lambda_i) \ge \min(2-e,0) - e \ge 1-2e$; and for $q^e < i \le 2n-1$, $v_q(\lambda_i) \ge -e-(e-1)$. In each case the product of the coefficient and λ_i has $v_q \ge 3-3e$, and 16^n and c_l are q-integral. The receipt checks every one of these estimates for $n \le 30$ and every odd prime $q \le 2n$; for instance $v_3\big((\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,26])\big) = -1$, $v_5\big((\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,24])\big) = 1$.

The prime 2. For $p \in \frac12+\mathbb{Z}$, $v_2\binom{p}{r} = -r - v_2(r!) \ge 1-2r$ for $r \ge 1$; the product of the two binomials in the coefficient, of total order $m-1-i \le 2n-1$, has $v_2 \ge 3-4n$; $v_2(1/t) \ge -\lfloor\log_2 2n\rfloor$; and $v_2(\lambda_i) \ge -2\lfloor\log_2 2n\rfloor$, from $v_2\big((\mathsf{T}_{1;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,i-1])\big) \ge -\lfloor\log_2(i-1)\rfloor$ and $v_2(i(i+1)) \le \lfloor\log_2(i+1)\rfloor$. So each term of $16^n\sum_l c_l\mathcal{J}[F[\cdot,p_l]]$ has $v_2 \ge -3\lfloor\log_2 n\rfloor = -v_2(d_n^3)$, and the heads, w_l times 8 times odd denominators, are 2-integral. Hence $256^n d_n^3 b_{n+1} \in \mathbb{Z}$.

The numbers. The receipt checks both statements for $k \le 80$. The first denominators, with their parts at 2:

k	2	3	4	5	6	7	8
$\operatorname{den}(b_k)$	2^3	2^9	$2^9\cdot 9$	$2^{21}\cdot 9$	$2^{25}\cdot 1125$	$2^{29}\cdot 125$	$2^{32}\cdot 42875$
d_{k-1}^3	1	2^3	$2^3\cdot 27$	$2^6\cdot 27$	$2^6\cdot 3375$	$2^6\cdot 3375$	$2^6\cdot 1157625$

The frame. The sequences (a_k) and (b_k) both solve the law of Exercise 54.8: (a_k) by Exercise 54.10(i), and $b_k = a_k v - P(k)$ as a difference of two solutions. They are independent,

$(a_1,a_2)=(1,\frac{1}{16})$ and $(b_1,b_2)=(0,\frac{3}{8})$. Their frame (Proposition 38.11) $C_k=a_kb_{k+1}-a_{k+1}b_k$ has $C_1=\frac{3}{8}$ and $C_{k+1}=\frac{c_{4,0}(k)}{c_{4,2}(k)}C_k=\frac{k^3}{64(k+1)^3}C_k$, so

$$C_k=\frac{3}{8\cdot 64^{k-1}k^3}.$$

By Theorem 43.3(i), every integer D_k that clears the rows of $P(k)$ and $P(k+1)$ has $D_k^2\geq|C_k|^{-1}=\frac{8}{3}\,64^{k-1}k^3$, so $\liminf_k\frac{1}{k}\log D_k\geq\log 8$. The clearing found grows like 256^k times d_{k-1}^3; its merit (Definition 43.4) is at most $-\log f(\alpha^\star)-\log 256=\log 16-\log 256=-\log 16$, so Theorem 43.5(ii) does not apply to these rows. For every clearing the frame bounds the merit by $\log 16-\log 8=\log 2$, and Corollary 43.9, with the ratio $\frac{1}{64}$, by $-\log 4+\liminf_k\frac{1}{k}\log\gcd\big(64^{k-1},\mathsf{C}_{k-1}(1)\big)$.

So the row of $P(k)$ is cleared by $256^{k-1}d_{k-1}^3$: the coefficient a_k by 64^{k-1}, the rational part b_k by 256^{k-1} at the prime 2 and by d_{k-1}^3 at the odd primes. □

54.8 The centre of $\binom{[5]}{1}$

The list $\binom{[5]}{1}$ has the marks $1,\dots,5$ and the five singletons as its bases, every weight 1. Its centre ray at the strength one has the stride $f=\big(K(\alpha)K(\alpha^{-1})\big)^{-1}$, $K(\alpha)=\sum_{e=1}^5\alpha_e$, the walls $\kappa_{1,S}=1$ for every nonempty proper S, the volume of the direction $V_1=5!=120$, and the values $P(k)=\langle 1\rangle_k=P_{\binom{[5]}{1}}(k\mathbf{1};k,k)$. In this section P_4 denotes the values of the centre ray of $\binom{[4]}{1}$, continued in the strength, and $v=P_4(1)=7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ (Section 54.7); $\mathsf{g}(y)=\mathsf{G}_{0;(1,-1)}(1,y)$ and $\mathsf{h}(y)=\sum_{m\geq 0}y^m/m!^2$, both solutions of $\vartheta^2u=yu$, $\vartheta=y\frac{d}{dy}$ (Exercise 54.8; $\vartheta^2y^m=m^2y^m$ gives $\vartheta^2\mathsf{h}=y\,\mathsf{h}$).

Exercise 54.12 (The law, the low-end relation and the value span)**.** (i) Compute the operators $\mathbf{R}_2,\dots,\mathbf{R}_6$ of Theorem 42.12 for $n=5$ and the law of the values $\sum_{k=0}^3 c_{5,k}(s)\,P(s+k)=0$.

(ii) Give the closings $\mathsf{C}_j(1)$ for $j\leq 6$, the symbol, its roots and their native gauges.

(iii) Write the low-end relation and the value span, and write $\Gamma(s)^2P(s)$ for $s=3,4$ in 1, $P(1)$ and $P(2)$.

Solution. Receipt: `ex25a_law.py`.

(i) As in Exercise 54.8, Corollary 18.24 and Proposition 8.15 give $\Gamma(s)^2P(s)=\int_0^\infty y^{s-1}\mathsf{g}(y)^5dy$. Theorem 42.12(i) at $n=5$ has the coefficients $i(6-i)=5,8,9,8,5$ in $\mathbf{R}_{i+1}=\vartheta\mathbf{R}_i-i(6-i)\,y\,\mathbf{R}_{i-1}$:

$$\begin{aligned}
\mathbf{R}_2&=\vartheta^2-5y,\\
\mathbf{R}_3&=\vartheta^3-y(13\vartheta+5),\\
\mathbf{R}_4&=\vartheta^4-y(22\vartheta^2+18\vartheta+5)+45y^2,\\
\mathbf{R}_5&=\vartheta^5-y(30\vartheta^3+40\vartheta^2+23\vartheta+5)+y^2(149\vartheta+130),\\
\mathbf{R}_6&=\vartheta^6-y(35\vartheta^4+70\vartheta^3+63\vartheta^2+28\vartheta+5)+y^2(259\vartheta^2+518\vartheta+285)-225y^3.
\end{aligned}$$

The leading coefficients $1,-35,259,-225$ are those of $(\xi^2-25\eta)(\xi^2-9\eta)(\xi^2-\eta)$. Theorem 42.12(ii) gives

$$\begin{gathered}
c_{5,0}(s)=s^4,\qquad c_{5,1}(s)=-(35s^4+70s^3+63s^2+28s+5),\\
c_{5,2}(s)=(s+1)^2(259s^2+518s+285),\qquad c_{5,3}(s)=-225(s+1)^2(s+2)^2,
\end{gathered}$$

and the law $\sum_{k=0}^{3} c_{5,k}(s)P(s+k) = 0$ identically in s; every $c_{5,k}$ has degree 4 and $c_{5,k}(-s-k) = c_{5,k}(s)$. At $s = 1$ and $s = 2$ the coefficients are $(1, -201, 4248, -8100)$ and $(16, -1433, 21213, -32400)$.

(ii) The closings are $\mathsf{C}_j(1) = \sum_{|v|=j} \binom{j}{v}^2 = 1, 5, 45, 545, 7885, 127905, 2241225$ for $j \le 6$, and they satisfy $\sum_{i \le \min(3,j)} c_{5,i}(-j)\,\mathsf{C}_{j-i}(1) = 0$ (Corollary 39.36; the receipt checks $j \le 40$). The coefficients of s^4 give the symbol

$$\chi_5(\lambda) = 1 - 35\lambda + 259\lambda^2 - 225\lambda^3 = (1-\lambda)(1-9\lambda)(1-25\lambda),$$

with the roots $\frac{1}{25}, \frac{1}{9}, 1$. By Proposition 42.9(ii) they are the native values $K(\eta)^{-2}$ of the signs: $\eta = \mathbf{1}$, with $K = 5$, the native gauge of the direction; the signs with one or four marks at -1, $K = \pm 3$; and those with two or three marks at -1, $K = \pm 1$.

(iii) *The low-end relation.* By Corollary 39.38(ii), with $[s^4]c_{5,0} = 1$, $\mathsf{L}_0 = V_1 = 120$ and $\big(c_{5,1}(0), c_{5,2}(0), c_{5,3}(0)\big) = (-5, 285, -900)$,

$$120 - 5P(1) + 285P(2) - 900P(3) = 0, \qquad P(3) = \frac{2}{15} - \frac{1}{180}P(1) + \frac{19}{60}P(2).$$

The value span. The law has order 3 and its last coefficient does not vanish at the positive integers, so every value is a rational combination of 1, $P(1)$ and $P(2)$: the value span of the ray is $\mathbb{Q} + \mathbb{Q}\,P(1) + \mathbb{Q}\,P(2)$ (Corollary 42.15(i), $h = 3$). The law at $s = 1$ gives $P(4) = \big(P(1) - 201P(2) + 4248P(3)\big)/8100$, so

$$\Gamma(3)^2 P(3) = \frac{8}{15} - \frac{1}{45}P(1) + \frac{19}{15}P(2),$$
$$\Gamma(4)^2 P(4) = \frac{944}{375} - \frac{113}{1125}P(1) + \frac{1907}{375}P(2).$$

As renderings, $P(1) = 39.94558801199624569894\ldots$, $P(2) = 0.2946961074182751313903\ldots$ and $P(3) = 0.00473383839491413155016 85\ldots$ (quadrature of the share side, a check; Exercise 54.15 reads them exactly from the gauge end). □

Exercise 54.13 (The exact pairing and the Hessian)**.** Show that for every integer $\sigma \ge 1$ the concomitant

$$B(\sigma) = \sum_{i=1}^{3} \sum_{j=1}^{i} c_{5,i}(\sigma - j)\,\mathsf{C}_{\sigma-j}(1)\,P(\sigma - j + i),$$

with the closings at negative indices read as 0, equals -120. Deduce $\det H$, H the Hessian of $-\log f$ at $\mathbf{1}$ on the chart $\alpha_5 = 1$, and compute H directly.

Solution. Receipt: `ex25b_pairing.py`.

The adjoint. The law is self-adjoint under the reflection of the strength: $c_{5,i}(-\sigma - i) = c_{5,i}(\sigma)$ for $i = 0, \ldots, 3$ (Exercise 54.12), so $c_{5,i}(\sigma - i) = c_{5,i}(-\sigma)$, and $\sum_i c_{5,i}(\sigma - i)\,\mathsf{C}_{\sigma-i}(1) = \sum_i c_{5,i}(-\sigma)\,\mathsf{C}_{\sigma-i}(1)$ is the law of the closings at $j = \sigma$, which vanishes for $\sigma \ge 0$; for $\sigma < 0$ every closing in it is 0. The closings solve the adjoint recurrence (Proposition 42.8(i)).

The concomitant is constant. Shifting j by one in $B(\sigma + 1)$,

$$B(\sigma+1) - B(\sigma) = \mathsf{C}_\sigma(1) \sum_{i=1}^{3} c_{5,i}(\sigma)P(\sigma + i) - P(\sigma) \sum_{i=1}^{3} c_{5,i}(\sigma - i)\,\mathsf{C}_{\sigma-i}(1),$$

and by the law and the adjoint recurrence the two sums are $-c_{5,0}(\sigma)P(\sigma)$ and $-c_{5,0}(\sigma)\mathsf{C}_\sigma(1)$, so the difference vanishes (the receipt checks the identity symbolically). At $\sigma=1$ only $j=1$ survives, and by the low-end relation of Exercise 54.12

$$B(1) = -5P(1) + 285P(2) - 900P(3) = -120.$$

At $\sigma=2$, with $\mathsf{C}_1(1)=5$, the five terms are $-201\cdot 5\,P(2)$, $4248\cdot 5\,P(3)$, $285\,P(2)$, $-8100\cdot 5\,P(4)$ and $-900\,P(3)$, so $B(2) = -720P(2) + 20340P(3) - 40500P(4)$; with the rows of Exercise 54.12,

$$20340P(3) = 2712 - 113P(1) + 6441P(2), \qquad 40500P(4) = 2832 - 113P(1) + 5721P(2),$$

and $B(2)=-120$, the coefficients of $P(1)$ and $P(2)$ cancelling. The receipt checks $B(\sigma)=-120$ exactly in the value span for $\sigma\le 50$. This is Corollary 42.16 at $n=5$, with $(-1)^n n! = -120$.

The limit. Every $c_{5,i}$ has degree $4 = n-1$, $\chi_5(0)=1$, and $\lambda_\star = \frac{1}{25}$ is a simple root. By Proposition 42.8(iii),

$$V_1 \det H = -\frac{\lambda_\star \chi_5'(\lambda_\star)}{\chi_5(0)} = \prod_{c\neq\star}\Big(1-\frac{\lambda_\star}{\lambda_c}\Big):$$

$$\chi_5'\big(\tfrac{1}{25}\big) = -25\cdot\frac{24}{25}\cdot\frac{16}{25} = -\frac{384}{25}, \qquad \Big(1-\frac{9}{25}\Big)\Big(1-\frac{1}{25}\Big) = \frac{384}{625},$$

so $120\det H = \frac{384}{625}$ and $\det H = \frac{16}{3125} = \frac{2^4}{5^5}$.

Directly. By Theorem 38.15 at the centre, $H = 2\big(\kappa_{\mathbf{1}}(X_e, X_{e'})\big)_{e,e'\neq 5}$, the covariances of the indicators under the weight law at $\mathbf{1}$, which picks one mark of five with the chance $\frac{1}{5}$: $\operatorname{Var} X_e = \frac{1}{5} - \frac{1}{25}$ and $\operatorname{Cov}(X_e, X_{e'}) = -\frac{1}{25}$. So

$$H = 2\Big(\frac{1}{5}I - \frac{1}{25}J\Big) = \frac{1}{25}\begin{pmatrix} 8 & -2 & -2 & -2 \\ -2 & 8 & -2 & -2 \\ -2 & -2 & 8 & -2 \\ -2 & -2 & -2 & 8 \end{pmatrix},$$

J the matrix of ones, with the eigenvalues $\frac{2}{5}$ on the vectors of sum zero and $\frac{2}{25}$ on $\mathbf{1}$: $\det H = \big(\frac{2}{5}\big)^3\frac{2}{25} = \frac{16}{3125}$, as Proposition 42.9(ii) gives at $\eta=\mathbf{1}$, $(2\sigma)^{n-1}/K(\mathbf{1})^n = 2^4/5^5$.

So $B(\sigma) = -120$ at every strength, the low-end relation carried to every σ, and its limit at high strength gives $\det H = 2^4/5^5$, the value of the Hessian computed directly. □

Exercise 54.14 (The lowered settings and the frame)**.** For $j=0,1,2$ the lowered setting with j marks lowered is $\xi_{5,j}(s) = \Gamma(s)^{-2}\int_0^\infty y^{s-1}\mathsf{g}(y)^{5-j}\mathsf{h}(y)^j\,dy$ (Proposition 42.14); put $x^{(j)}(s) = \Gamma(s)^2\xi_{5,j}(s)$, so that $x^{(0)}(s) = \Gamma(s)^2P(s)$.

(i) Show that the $x^{(j)}$ satisfy the law of Exercise 54.12 in this normalization, and find their low-end coefficients and their rates.

(ii) Write the frame $\Phi(s) = \det\big[x^{(i)}(s+l)\big]_{i,l=0}^{2}$ in terms of $\Phi(1)$, and find $\Phi(1)$ from the behaviour of the $x^{(j)}$ at large s.

(iii) Deduce the value of $x^{(1)}(1)\,x^{(2)}(2) - x^{(1)}(2)\,x^{(2)}(1)$.

Solution. Receipt: `ex25c_lowered.py`.

(i) *The law.* $\mathsf{g}^{5-j}\mathsf{h}^j$ is a product of five solutions of $\vartheta^2 u = yu$, so $\mathbf{Q}_5 = \mathbf{R}_6$ annihilates it (Theorem 42.12(i)), and integration against y^{s-1} turns it into the law for $x(s) = \Gamma(s)^2\xi(s)$:

$$s^6x(s) - (35s^4+70s^3+63s^2+28s+5)\,x(s+1) + (259s^2+518s+285)\,x(s+2) - 225\,x(s+3) = 0,$$

the coefficients being $q_{5,k}(-s-k)$; this is the law of Exercise 54.12 multiplied by $\Gamma(s)^2 s^2$ (Proposition 42.14(i)). The boundary terms vanish: near 0, $\mathsf{g}^{5-j}\mathsf{h}^j = O(|\log y|^{5-j})$ (Lemma 20.29(i)), and for $y \ge 1$, $\mathsf{g} \le \sqrt{\pi}\, y^{-1/4} e^{-2\sqrt{y}}$ (Lemma 20.29(ii)) and $\mathsf{h} \le e^{2\sqrt{y}}$, so the integrand decays like $e^{-2(5-2j)\sqrt{y}}$, $j < \frac{5}{2}$.

The low-end coefficients. Near $y = 0$, $\mathsf{g}(y) = -\log y + 2(\log\Gamma)'(1) + O(y|\log y|)$ (Lemma 20.29(i)) and $\mathsf{h}(y) = 1 + O(y)$, and $\int_0^1 y^{s-1}(-\log y)^{5-j} dy = \Gamma(6-j)\, s^{j-6}$; so $x^{(j)}(s) = \Gamma(6-j)\, s^{j-6}\big(1+O(s)\big)$ and $s^4 \xi_{5,j}(s) \to 120, 0, 0$ for $j = 0, 1, 2$, $\Gamma(s)^{-2}$ being $s^2(1+O(s))$. Read at $s \to 0$, the law gives

$$-5x^{(j)}(1) + 285x^{(j)}(2) - 225x^{(j)}(3) = -120,\ 0,\ 0 \qquad (j = 0, 1, 2):$$

the lowered settings with $j \ge 1$ have no low-end coefficient (Proposition 42.14(ii)).

The rates. $x^{(j)}(s+1)/\big(s^2 x^{(j)}(s)\big) \to (5-2j)^{-2} = \frac{1}{25}, \frac{1}{9}, 1$ (Proposition 42.14(iii)): the setting with j marks lowered carries the native value of the signs with j marks at -1. This also follows from the amplitudes below.

(ii) *The frame.* The end coefficients of the law in x are s^6 and -225, with no zero at the integers $s \ge 1$, so Proposition 38.11 gives $\Phi(s+1) = (-1)^3 \frac{s^6}{-225}\Phi(s) = \frac{s^6}{225}\Phi(s)$ and

$$\Phi(s) = \Phi(1)\,\Gamma(s)^6\, 225^{1-s}.$$

One mark at large y. By the torus homogeneity (Theorem 2.4(iii)) $\mathsf{g}(y) = \mathsf{G}_{0;(1,-1)}(\lambda, \lambda)$ with $\lambda = \sqrt{y}$, and Theorem 4.3(iii) at $t = (1, -1)$, $\boldsymbol{\xi} = (1, 1)$, $\nu = \nu' = 0$ applies: $\Phi_{\boldsymbol{\xi}}(y') = e^{y'} + e^{-y'}$, $y^\star = 0$, $\Phi_{\boldsymbol{\xi}}(0) = 2$, $\sum_k w_k^\star t_k^2 = 2$, so

$$\mathsf{g}(y) = e^{-2\sqrt{y}}\Big(\frac{2\pi}{\sqrt{y}}\Big)^{\frac{1}{2}} 2^{-\frac{1}{2}}\big(1 + O(y^{-\frac{1}{2}})\big) = \sqrt{\pi}\, y^{-\frac{1}{4}} e^{-2\sqrt{y}}\big(1 + O(y^{-\frac{1}{2}})\big).$$

$\mathsf{h}(y)$ is the constant term of $e^{\sqrt{y}(z+z^{-1})}$, that is $\frac{1}{2\pi}\int_{-\pi}^{\pi} e^{2\sqrt{y}\cos\theta} d\theta$, and Laplace's method (an outside result; it applies because $\cos\theta$ has one maximum on the circle, at $\theta = 0$, where its second derivative is -1) gives $\mathsf{h}(y) = e^{2\sqrt{y}}(4\pi\sqrt{y})^{-1/2}\big(1 + O(y^{-1/2})\big)$. So, with $\rho_j = 2(5-2j) = 10, 6, 2$,

$$\mathsf{g}^{5-j}\mathsf{h}^j = \pi^{\frac{5-2j}{2}} 2^{-j}\, y^{-\frac{5}{4}} e^{-\rho_j\sqrt{y}}\big(1 + O(y^{-\frac{1}{2}})\big).$$

The amplitudes. With $y = u^2$, $x^{(j)}(s) = 2\int_0^\infty u^{2s-1}\mathsf{g}(u^2)^{5-j}\mathsf{h}(u^2)^j\, du$; the part $u \le u_0$ is $O(u_0^{2s})$, negligible against $\Gamma(2s)\rho_j^{-2s}$, and the rest gives

$$x^{(j)}(s) = A_j\,\Gamma\big(2s - \tfrac{5}{2}\big)\,\rho_j^{-2s}\big(1 + O(s^{-1})\big), \qquad A_j = 2\pi^{\frac{5-2j}{2}} 2^{-j} \rho_j^{\frac{5}{2}},$$

$A_0 = 200\sqrt{10}\,\pi^{5/2}$, $A_1 = 36\sqrt{6}\,\pi^{3/2}$, $A_2 = 2\sqrt{2}\,\pi^{1/2}$, $\prod_j A_j = \pi^{9/2}\, 120^{5/2}$. Factoring $A_i\rho_i^{-2s}$ out of the rows and $\Gamma(2s + 2l - \frac{5}{2})$ out of the columns,

$$\Phi(s) = \prod_i A_i \rho_i^{-2s} \prod_{l=0}^{2} \Gamma\big(2s + 2l - \tfrac{5}{2}\big)\big(V + O(s^{-1})\big), \qquad V = \det\big[u_i^l\big] = \prod_{i<i'}(u_{i'} - u_i) = \frac{16}{16875},$$

$u_i = \rho_i^{-2} = \frac{1}{100}, \frac{1}{36}, \frac{1}{4}$. Theorem 4.3(iii) for $\Gamma(\lambda + a) = \lambda^{\lambda+a}\mathsf{G}_{\lambda+a;(1)}(\lambda)$, with $\Phi_\xi(y') = e^{y'} - y'$, $y^\star = 0$ and $w^\star = 1$, gives $\Gamma(\lambda + a) = \lambda^{\lambda+a} e^{-\lambda}(2\pi/\lambda)^{1/2}\big(1 + O(\lambda^{-1})\big)$, hence $\prod_l \Gamma(2s + 2l - \frac{5}{2}) = \Gamma(2s)^3 (2s)^{-3/2}\big(1 + O(s^{-1})\big)$ and $\Gamma(2s) = 2^{2s-1}\pi^{-1/2} s^{1/2}\Gamma(s)^2\big(1 + O(s^{-1})\big)$, so

$$\Phi(s) = \prod_j A_j \cdot V \cdot 2^{-\frac{9}{2}}\pi^{-\frac{3}{2}}\,\Gamma(s)^6\Big(\frac{64}{\prod_j \rho_j^2}\Big)^s\big(1 + O(s^{-1})\big), \qquad \frac{64}{\prod_j \rho_j^2} = \frac{64}{14400} = \frac{1}{225}.$$

Comparing with $\Phi(s) = 225\,\Phi(1)\,\Gamma(s)^6\,225^{-s}$,

$$\Phi(1) = \frac{\pi^{9/2}\,120^{5/2}}{225}\cdot\frac{16}{16875}\cdot\frac{1}{2^{9/2}\pi^{3/2}} = \frac{128\sqrt{15}}{16875}\,\pi^3 = \frac{128\sqrt{15}}{16875}\,\Gamma\big(\tfrac12\big)^6,$$

which is $0.91088056479820303289039 72\ldots$ to 25 places; the receipt computes the nine settings by quadrature and reproduces it, and checks the law, the low-end coefficients and the amplitudes.

(iii) *The block.* By (i), $x^{(j)}(3) = \big(-5x^{(j)}(1) + 285x^{(j)}(2) + 120\,\delta_{j0}\big)/225$, so subtracting $-\frac{5}{225}$ times the first column and $\frac{285}{225}$ times the second from the third leaves the column $(\frac{120}{225}, 0, 0)$:

$$\Phi(1) = \frac{120}{225}\Big(x^{(1)}(1)\,x^{(2)}(2) - x^{(1)}(2)\,x^{(2)}(1)\Big), \qquad x^{(1)}(1)\,x^{(2)}(2) - x^{(1)}(2)\,x^{(2)}(1) = \frac{16\sqrt{15}}{1125}\,\Gamma\big(\tfrac12\big)^6,$$

which is $1.70790105899663068666949 5\ldots$ to 24 places. The values $P(1), P(2)$ do not enter Φ: their coefficients are minors that the vanishing low-end coefficients of the lowered settings remove. □

Exercise 54.15 (The reading from the gauge end)**.** Read $P(1)$, $P(2)$ and $P(3)$ from the gauge end (Theorem 40.6, Definition 40.10): the native gauge and the constant $g(0)$; the density operator of the law and its exponents at $f^\star = \frac{1}{25}$; the germs that extend by zero; the Taylor coefficients of the germ; the values at a large strength and the law run back; and the low-end relation read on the output.

Solution. Receipt: `ex25d_gauge.py`.

(1) *The native gauge.* $\alpha^\star = \mathbf{1}$ (Theorem 38.14), $f^\star = f(\mathbf{1}) = \frac{1}{25}$, $\det H = \frac{16}{3125}$ (Exercise 54.13) and $(\omega_0/dy)(\mathbf{1}) = 1$, the origin being 0. By Proposition 40.3(ii), with $n = 5$,

$$g(0) = \frac{1}{\Gamma(2)\sqrt{\det H}}\Big(\frac{2\pi}{f^\star}\Big)^2 = \frac{25\sqrt5}{4}\,(50\pi)^2 = 15625\sqrt5\,\Gamma\big(\tfrac12\big)^4.$$

(2) *The operator.* The density operator of the law $\mathbf{p} = (c_{5,0}, \ldots, c_{5,3})$ is $\mathfrak{D}_\mathbf{p} = \sum_i t^i c_{5,i}(-1 - i - \theta)$, $\theta = t\frac{d}{dt}$ (Definition 40.4). With $\theta^m = \sum_j S(m,j)\,t^j\partial_t^j$, $S(m,j)$ the number of partitions of a set of m elements into j nonempty parts, $\mathfrak{D}_\mathbf{p} = \sum_{j=0}^4 a_j(t)\partial_t^j$ with

$$\begin{aligned}
a_0 &= 1 - 201t + 4248t^2 - 8100t^3,\\
a_1 &= -t\,(24300t^3 - 16965t^2 + 1232t - 15),\\
a_2 &= -t^2(16650t^3 - 14271t^2 + 1358t - 25),\\
a_3 &= -2t^3(1800t^3 - 1813t^2 + 210t - 5),\\
a_4 &= -t^4(t-1)(9t-1)(25t-1) = t^4\chi_5(t).
\end{aligned}$$

In $s = \frac{1}{25} - t$, $\mathfrak{D}_\mathbf{p} = \sum_j b_j(s)\partial_s^j$ with $b_{4,0} = 0$ and $b_{4,1} = -(f^\star)^4\chi_5'(f^\star) = \frac{384}{25^5}$. The second symbol is $\chi_1(\lambda) = -70\lambda + 1036\lambda^2 - 1350\lambda^3$, and Theorem 40.6(i) gives

$$\gamma = -1 + \frac{\chi_1(f^\star)}{f^\star\chi_5'(f^\star)} = -1 + \frac{-768/625}{-384/625} = 1 = \frac{n-3}{2}, \qquad R_0(x) = \frac{384}{25^5}\,x(x-1)^2(x-2)\,:$$

the exponents at $f^\star$ are $0, 1, 2$ and $\gamma = 1$, a double root. The further polynomials $R_m(x) = \sum_j b_{j,m-3+j}[x]_j$ are

$$R_1 = -\tfrac{8}{25^4}\,x(x-1)(163x^2 - 67x + 72), \qquad R_2 = \tfrac{1}{25^3}\,x(1385x^3 + 1840x^2 + 1631x + 576),$$

$$R_3 = -\tfrac{1}{625}(180x^4 + 1290x^3 + 2129x^2 + 1619x + 476),$$
$$R_4 = -\tfrac{1}{25}(490x^4 + 2530x^3 + 5454x^2 + 5789x + 2499),$$
$$R_5 = (x+2)^2(196x^2 + 802x + 819), \qquad R_6 = 225(x+2)^2(x+3)^2,$$

and $R_m = 0$ for $m \geq 7$.

(3) *The line.* As $\gamma = 1 \in \{0, 1, 2\}$, the germ is $\varrho_f = \sum_r u_r s^r$ with $u_0 = 0$, $u_1 = g(0)$ (Theorem 40.6(iv)). The germs that extend by zero are fixed by the conditions $\mathsf{p}_r(u) = 0$, $r \leq 2$, the point masses of $\mathfrak{D}_{\mathbf{p}}$ applied to the germ cut at $f^\star$:

$$\mathsf{p}_0(u) = -\frac{384}{25^5}u_0, \qquad \mathsf{p}_1(u) = -\frac{576}{25^4}u_0, \qquad \mathsf{p}_2(u) = \frac{576}{25^3}u_0 - \frac{1344}{25^4}u_1 + \frac{768}{25^5}u_2,$$

the coefficient of u_r in p_r being $r!\, b_{4,1}(r-\gamma)$. They leave one line, $u_0 = 0$ and $u_2 = \frac{1344 \cdot 25}{768}u_1 = \frac{175}{4}u_1$ (Theorem 40.6(ii)): the germ vanishes to the first order, as the exponent $\gamma = 1$ says, and the receipt also derives the three conditions from the distributional derivatives of the cut germ.

(4) *The germ.* For $N \geq 3$, $R_0(N)u_N = -\sum_{m=1}^{\min(N,6)} R_m(N-m)\, u_{N-m}$. At $N = 3$, $R_0(3) = \frac{4608}{25^5}$, $R_1(2) = -\frac{9440}{25^4}$, $R_2(1) = \frac{5432}{25^3}$, so

$$u_3 = -\frac{25^5}{4608}\Big(-\frac{9440}{25^4}\cdot\frac{175}{4} + \frac{5432}{25^3}\Big)u_1 = \frac{48125}{32}u_1, \qquad u_4 = \frac{35703125}{768}u_1,$$

and the receipt continues to u_{400}, all rational multiples of u_1, and checks that the series solves $\mathfrak{D}_{\mathbf{p}}\varrho = 0$ to the order kept.

(5) *Large strengths.* The singular points of $\mathfrak{D}_{\mathbf{p}}$ in t are $0, \frac{1}{25}, \frac{1}{9}, 1$, so the series converges for $|s| < \frac{1}{25}$, on $0 < t \leq f^\star$, and by Proposition 40.9(ii) at $j = 0$

$$P(K) = \int_0^{f^\star} t^K \varrho_f(t)\, dt = g(0)\sum_{r\geq 1}\frac{u_r}{u_1}\,(f^\star)^{K+r+1}\,\mathrm{B}(K+1, r+1),$$

the terms falling like $\prod_{i\leq r}\frac{i}{K+1+i}$; at $K = 150$ the term $r = 400$ is $3 \cdot 10^{-136}$ of the sum. These are the values at $K = 150, 151, 152$.

(6) *The run back.* The law holds at every positive integer (Proposition 40.5), and $c_{5,0}(k) = k^4 \neq 0$, so $P(k) = -\big(c_{5,1}(k)P(k+1) + c_{5,2}(k)P(k+2) + c_{5,3}(k)P(k+3)\big)/k^4$ from $k = 149$ down to $k = 1$. In 150-digit arithmetic, with the renderings to 60 places,

$$P(1) = 39.945588011996245698944028498423995891849782924769859572366 6\ldots,$$
$$P(2) = 0.294696107418275131390303208655999730074422376946254727936899\ldots,$$
$$P(3) = 0.004733833949141315501684746638711048457734958673148110666870 36\ldots,$$

and the reading from $K = 250$ agrees to 10^{-133}.

(7) *Checks.* The low-end relation read on the output (Definition 40.10 step (7)) gives $5P(1) - 285P(2) + 900P(3) = 120.000\ldots$ to all the places computed: the output returns $V_1 = 120$, which the reading did not use. The values agree with the quadrature of Exercise 54.12 to its 22 places.

So $P_{\binom{[5]}{1}}(\mathbf{1}; 1, 1) = 39.945588011996245698944028498 42\ldots$, read from the law, the native gauge $\mathbf{1}$ and $\det H$ alone, with the germ of the density ϱ_f exact over $\mathbb{Q}$ up to the factor $15625\sqrt{5}\,\Gamma(\frac{1}{2})^4$. $\square$

Exercise 54.16 (The value as a Trailmoment of the slope input of four marks)**.** Let $\tilde{p}_4 = -P_4'$ be the slope input of the centre ray of $\binom{[4]}{1}$ (Definition 42.1). Show that $P(1) = (\mathsf{T}_{0;(1)}[x]\,\tilde{p}_4\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = \sum_{x\geq 1}\tilde{p}_4(x)$, find the recurrence of the slope input and its relation at the cut, and write $\tilde{p}_4(m)$, $m \leq 5$, in 1, v and $\tilde{p}_4(1)$.

Solution. Receipt: `ex25e_slope.py`.

The mark added. By Proposition 42.11(i), merging four marks, $\Gamma(s)^2 P(s) = \frac{1}{2\pi i}\int_{(c)} \Gamma(d)^2\Gamma(s-d)^2 P_4(d)\,dd$; at $s=1$ the kernel is $\Gamma_4^{\,0}\big[d,\ d,\ 1-d,\ 1-d\big]$, whose right closing reads the derivative of the rest at the positive integers (Lemma 5.16(i)). Proposition 42.11(ii) at $s=1$, with $W_1 = 1$, gives

$$P(1) = (\mathsf{T}_{0;(1)}[x]\,\tilde{p}_4\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = \sum_{x\geq 1}\tilde{p}_4(x)\,:$$

the centre of five marks at the strength one is the slope input of four marks summed over the positive integers.

The recurrence. By Proposition 42.2(ii), $L\tilde{p}_4 = L'P_4$ for the law L of Exercise 54.8:

$$\sum_{i=0}^{2} c_{4,i}(\sigma)\,\tilde{p}_4(\sigma+i) = \sum_{i=0}^{2} c'_{4,i}(\sigma)\,P_4(\sigma+i),$$
$$c'_{4,0} = -3\sigma^2, \qquad c'_{4,1} = 6(10\sigma^2+10\sigma+3), \qquad c'_{4,2} = -192(\sigma+1)^2.$$

The cut. Proposition 42.6 at $x_0 = 0$, $j=0$, with $c_{4,0} = -\sigma^3$, so $\gamma_3 = -1$ and $\gamma_4 = 0$, and with $\ell_1 = 0$, every weight being 1:

$$\sum_{i=1}^{2}\big(c_{4,i}(0)\,\tilde{p}_4(i) - c'_{4,i}(0)\,P_4(i)\big) = \gamma_3\ell_1 + \gamma_4 V_1 = 0, \qquad 4\tilde{p}_4(1) - 64\tilde{p}_4(2) - 18P_4(1) + 192P_4(2) = 0.$$

With $P_4(1) = v$ and $P_4(2) = \frac{1}{16}v - \frac{3}{8}$ (Exercise 54.8),

$$\tilde{p}_4(2) = \frac{1}{16}\tilde{p}_4(1) - \frac{3}{32}v - \frac{9}{8}.$$

The rows. The recurrence, whose coefficient $c_{4,2}(m) = -64(m+1)^3$ does not vanish, gives every slope from the first two:

$$\tilde{p}_4(3) = \tfrac{7}{1024}\tilde{p}_4(1) - \tfrac{57}{4096}v - \tfrac{279}{2048},$$
$$\tilde{p}_4(4) = \tfrac{1}{1024}\tilde{p}_4(1) - \tfrac{73}{32768}v - \tfrac{2819}{147456},$$
$$\tilde{p}_4(5) = \tfrac{679}{4194304}\tilde{p}_4(1) - \tfrac{13081}{33554432}v - \tfrac{463499}{150994944},$$

the coefficient of $\tilde{p}_4(1)$ being a_m of Exercise 54.8, since the recurrence has the law as its homogeneous part. So every $\tilde{p}_4(m)$ lies in $\mathbb{Q} + \mathbb{Q}\,v + \mathbb{Q}\,\tilde{p}_4(1)$.

The value. The slopes have the root rate $\frac{1}{16}$ along the positive integers (Proposition 42.2(iii)). As renderings, $\tilde{p}_4(1) = -P_4'(1) = 39.381582123122165624939809345 1\ldots$ by quadrature of $-\int_0^\infty \log y\,\mathsf{g}(y)^4 dy + 2(\log\Gamma)'(1)\,v$, then $\tilde{p}_4(2) = 0.547499039997\ldots$, $\tilde{p}_4(3) = 0.0158846667692\ldots$, $\tilde{p}_4(4) = 0.00059555377139\ldots$, $\tilde{p}_4(5) = 0.0000253984887\ldots$ from the rows; the sum over $m \leq 70$ is $39.945588011996245694894402849842\ldots$, the value of Exercise 54.15 to all 36 places computed, and the steps $m \geq 2$ add $0.564005888874080074\ldots$ to the first slope. The receipt also checks Proposition 42.11(iii) at $n=4$, $5\,(\mathsf{T}_{0;(1)}[x]\,P_4\mathbb{I}_{\mathbb{Z}})((0,\infty)) - 5\,(\mathsf{T}_{0;(1)}[x]\,(x-1)\,\tilde{p}_4\mathbb{I}_{\mathbb{Z}})((0,\infty)) = (\mathsf{T}_{0;(1)}[x]\,\tilde{p}_4\mathbb{I}_{\mathbb{Z}})((0,\infty))$.

So $P_{\binom{[5]}{1}}(\mathbf{1};1,1) = (\mathsf{T}_{0;(1)}[x]\,\tilde{p}_4\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$, a Trailmoment at the index zero of the slope input of four marks, whose density lies in $\mathbb{Q} + \mathbb{Q}\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) + \mathbb{Q}\,\tilde{p}_4(1)$ at every point. □

54.9 W_3 at $(\mathbf{1}; 0, 2)$

The wheel W_3 (Proposition 39.65) has the hub, the rim vertices $1, 2, 3$, the spokes s_1, s_2, s_3 and the rims r_1, r_2, r_3, r_i joining i to $i+1$; its bases are the 16 spanning trees, the triples of marks other than the four triangles $\{r_1, r_2, r_3\}$, $\{s_1, s_2, r_1\}$, $\{s_2, s_3, r_2\}$, $\{s_3, s_1, r_3\}$, its rank is 3, its cobases are the complements of the bases and every weight is 1. The ray of this section has the origin 0 and the direction $(\mathbf{1}; 0, 2)$: masses 1, exponent 0 for K and 2 for Ψ, on the balance wall, $m_{\mathcal{E}} = 6 = 0 \cdot 3 + 2 \cdot 3$. Its stride is $f = \alpha^{\mathbf{1}}/\Psi^2$, only Ψ being active; its walls are $\kappa_{1,S} = |S| - 2\big(|S| - r(S)\big) = 2r(S) - |S|$, with the values $1, 2, 3$ on the nonempty proper S; and its volume of the direction is $V_1 = \sum_\pi \prod_{l=2}^{6} \kappa_{1,U_l}^{-1} = 84$. At $\mathbf{1}$ every mark lies in 8 of the 16 bases, so every dual occupation is $\frac{1}{2}$, the defects $1 - 2 \cdot \frac{1}{2}$ vanish, and $\alpha^\star = \mathbf{1}$ with $f^\star = \Psi(\mathbf{1})^{-2} = \frac{1}{256}$. The values are $P(k) = \langle 1 \rangle_k = P_{W_3}(k\mathbf{1}; 0, 2k)$. Since K has the exponent 0, the constant terms of the powers of $f^{-1} = \Psi^2/\alpha^{\mathbf{1}}$ are written explicitly: $\mathrm{CT}(f^{-j}) = [\alpha^{j\mathbf{1}}]\, \Psi^{2j}$.

Exercise 54.17 (The box, the law and the spectrum)**.** (i) Read the box $\mathfrak{B}_2$ with one unit of Ψ (Definition 39.15) modulo the automorphisms of W_3, find its free orbits, and show that it is accepted at $\mathfrak{s} = 1$ with the spanning set $b_1 = 1$, $b_2 = b = \frac{1}{4} \sum_T \alpha^T/\alpha^{\mathcal{E}\setminus T}$, the sum over the four triangles T; give its matrix $\mathbf{B}(k)$.

(ii) Derive the law of [1] from the rows, its symbol, and show that b_1, b_2 are masters.

(iii) Show that $\mathbf{B}$ is not regular at $k = \infty$, and repair it by a change of masters.

Solution. Receipt: `ex26a_box.py` (with `w3common.py`).

(i) *Symmetries.* The 24 permutations of the four vertices of the graph induce permutations of the marks that carry the spanning trees onto themselves and keep the masses and the exponents: maps ϕ_β of the first kind of Proposition 39.11(ii), forming a group G. The level bounds are $\bar{a} = 0$, K being inactive, and $\bar{b} = 1$; G keeps Ψ, so it keeps the box.

The box. $\mathfrak{B}_2(0, 1)$ holds the symbols of wall degree at most 2 at the levels $(0, 0)$ and $(0, 1)$ (Definition 39.15(iv)): 1167 Laurent symbols α^u, $u_{\mathcal{E}} = 0$, which are the stems, and 2848 symbols at the level $(0, 1)$, $u_{\mathcal{E}} = 3$. Its relations are the letter identities of Ψ, $\alpha^u - \sum_T (u + \mathbf{1}_{\mathcal{E}\setminus T}; 0, 1)$, of the 1167 Laurent symbols, and the mark relations of the stems at the six marks (Definition 39.15(iii)), here, with the origin 0, $m_{1,e} = 1$, $s_1 = 0$ and $t_1 = 2$,

$$\mathrm{MR}_e(\alpha^u) = (k + u_e)\, \alpha^u - 2k \sum_{T \not\ni e} (u + \mathbf{1}_{\mathcal{E}\setminus T}; 0, 1),$$

7002 of them. Modulo G (Definition 39.20(i)) there are 66 Laurent orbits, of wall degrees 0 (one orbit), 1 (eight) and 2 (fifty-seven), and 145 orbits at the level $(0, 1)$: 211 orbit averages, on which the averaged relations, 389 distinct ones, have the rank 200 over $\mathbb{Q}(k)$.

The reduction. The ranking puts the orbits at the level $(0, 1)$ highest, then the Laurent orbits by decreasing wall degree, with the orbit of $\alpha^{r_1 r_2 r_3}/\alpha^{s_1 s_2 s_3}$ last among those of wall degree 1 (Definition 39.20(ii)). The free orbits are 11: nine at the level $(0, 1)$ and the Laurent orbits of 1 and of $\alpha^{r_1 r_2 r_3}/\alpha^{s_1 s_2 s_3}$. The latter orbit has four members, $\alpha^T/\alpha^{\mathcal{E}\setminus T}$ for the four triangles T, each with its complement the star at the opposite vertex; so the spanning set at $\mathfrak{s} = 1$ is $b_1 = 1$, $b_2 = b$ (Definition 39.20(iii)). The targets $f^{-1} b_1 = \Psi^2/\alpha^{\mathbf{1}}$ and $f^{-1} b_2$ involve 9 and 22 orbits.

Acceptance. The reductions of the two targets were computed by elimination at integer strengths and reconstructed over $\mathbb{Q}(k)$ (Proposition 41.10(i),(ii)); with the common denominator $Q_c = (k-1)^2 (k-2)^5 (k^2 - k + 1)$ every $Q_c \mathbf{B}_{il}$ is a polynomial of degree at most 10:

$$\mathbf{B}_{11} = -\frac{2(2k-1)(k^2 - 4k + 2)(7k^2 - 8k + 3)}{(k-1)^2 (k^2 - k + 1)}, \qquad \mathbf{B}_{12} = \frac{14k^2 (2k-1)}{k^2 - k + 1},$$

$$\mathbf{B}_{21} = -\frac{2k(k-3)(k-1)(k+1)(2k-1)(7k^2-14k+8)}{(k-2)^4(k^2-k+1)},$$
$$\mathbf{B}_{22} = \frac{2k^2(k-1)(2k-1)(k^2-2)(7k^2-20k+15)}{(k-2)^5(k^2-k+1)}.$$

The proof that these are the reductions over $\mathbb{Q}(k)$: for each target x_i the row $x_i - \sum_l \mathbf{B}_{il} b_l$, times Q_c, stacked under the relation matrix $A(k)$, whose entries are affine in k (Proposition 41.9(iii)), has the rank 200 at 230 integer strengths; its minors of order 201 are polynomials of degree at most 219, so they vanish identically, the row lies in $\mathcal{R}^G_{\mathfrak{B}}$ over $\mathbb{Q}(k)$, and $\sum_l \mathbf{B}_{il} b_l$, a combination of free orbits, is the reduction (Definition 39.20(ii)). So the box is accepted at $\mathfrak{s} = 1$ with the matrix $\mathbf{B}$, the classes of b_1, b_2 span a submodule $\mathfrak{N} \ni [1]$, there is a certificate supported on the stems, and $\langle b_i \rangle_{k-1} = \sum_l \mathbf{B}_{il}(k) \langle b_l \rangle_k$ at every strength (Theorem 39.21(i)–(iii)).

(ii) *The law.* With $w_0 = (1, 0)$ and $w_i(k) = w_{i-1}(k-1)\mathbf{B}(k)$, the first dependence is $q_0 w_0 + q_1 w_1 + q_2 w_2 = 0$ with

$$q_0 = 16(k-1)(2k-3)(2k-1)(4k-5)(4k-3), \qquad q_2 = (k-2)^5,$$
$$q_1 = -2(2k-3)(65k^4 - 390k^3 + 885k^2 - 900k + 346),$$

and $p_j(k) = q_{2-j}(k+2)$ (Proposition 39.6(ii), Theorem 39.21(iv)) gives

$$k^5 P(k) - 2(2k+1)(65k^4 + 130k^3 + 105k^2 + 40k + 6)\, P(k+1) + 16(k+1)(2k+1)(2k+3)(4k+3)(4k+5)\, P(k+2) = 0$$

at every strength (Corollary 39.38(i)). Its symbol is $1 - 260\lambda + 1024\lambda^2 = (1 - 4\lambda)(1 - 256\lambda)$, and at both roots the exponent $-\chi_1(\lambda)/(\lambda\chi'(\lambda))$, with the second symbol $\chi_1(\lambda) = 10\lambda(512\lambda - 65)$, is $-\frac{5}{2} = -\frac{n-1}{2}$ (Proposition 40.7). The constant terms $\mathrm{CT}(f^{-j}) = 1, 12, 756, 78960, 10451700, 1587790512, 263964176784$ ($j \le 6$) satisfy $\sum_i p_i(-j)\,\mathrm{CT}(f^{i-j}) = 0$ (Corollary 39.38(i)), a check.

Masters. Two native gauges: $\mathbf{1}$, with $\Psi = 16$, the native value $\frac{1}{256}$ and the determinant $\frac{3}{256}$ of the Hessian of $-\log f$ on the chart; and $\alpha_c = (1, \omega, \omega^2, \omega^2, 1, \omega)$ on $(s_1, s_2, s_3, r_1, r_2, r_3)$, $\omega = e^{2\pi i/3}$, at which every triangle and every star has the product 1, $\Psi(\alpha_c) = -2$, every dual occupation is $\frac{1}{2}$ (so $c^{(1)} = 0$), the native value is $\prod_e \alpha_{c,e}/\Psi^2 = \frac{1}{4}$, and the Hessian has the determinant $-\frac{3}{2}$. Both are nondegenerate with distinct native values, so by Corollary 38.7 at $g = 1$ every recurrence of $\langle 1 \rangle$ that follows from the relations has order at least 2: the cyclic submodule of $[1]$, inside $\mathfrak{N}$ of dimension at most 2, has dimension 2. So b_1, b_2 are masters, $\mathbf{B} = \mathbf{B_b}$, and the relation above is the law of [1].

(iii) *The spectrum.* $b(\alpha_c) = 1 = b(\mathbf{1})$, so the vectors $\beta_c = (1, 1)$ of the two native gauges are proportional with distinct native values, and $\mathbf{B}$ is not regular at $k = \infty$ (Proposition 39.42(ii)); indeed $\mathbf{B}(k)/k \to \begin{bmatrix} -28 & 28 \\ -28 & 28 \end{bmatrix}$. The change $T(k) = \begin{bmatrix} 1 & 0 \\ -k & k \end{bmatrix}$, to the elements $[1]$ and $k([b] - [1])$, gives $\tilde{\mathbf{B}}(k) = T(k-1)\mathbf{B}(k)T(k)^{-1}$ with

$$\tilde{\mathbf{B}}(\infty) = \begin{bmatrix} 88 & 28 \\ 504 & 172 \end{bmatrix}, \qquad \det\big(\lambda - \tilde{\mathbf{B}}(\infty)\big) = (\lambda - 256)(\lambda - 4),$$

the eigenvectors $(\frac{1}{6}, 1)$ and $(-\frac{1}{3}, 1)$: the reciprocals of the native values $\frac{1}{256}$ and $\frac{1}{4}$ (Proposition 39.42(iii)). As $T(k-1)T(k)^{-1} = \mathrm{diag}\big(1, \frac{k-1}{k}\big) \to I$, the eigenvalues of $\mathbf{B}(k)$ tend to 256 and 4: $\mathrm{tr}\,\mathbf{B}(k) \to 260$ and

$$\det \mathbf{B}(k) = \frac{16k^2(2k-1)^2(4k-5)(4k-3)(k^2-3k+3)}{(k-2)^5(k-1)(k^2-k+1)} \to 1024.$$

So the box gives the masters $1, b$, the matrix $\mathbf{B_b}$ above and the law of [1] of symbol $(1-4\lambda)(1-256\lambda)$; $\mathbf{B_b}$ grows like k, and the masters 1 and $k(b-1)$ repair it. □

Exercise 54.18 (The low-end relation, the brackets and the value)**.** From the law of Exercise 54.17: write the low-end relation; show $7 < P(1) < \frac{64}{7}$; give the brackets of the two conditions $P(K) > 0$ and $P(K) < f^\star P(K-1)$ at every K, their widths and their rate; and give $P(1)$.

Solution. Receipt: `ex26b_bracket.py`.

The low-end relation. By Corollary 39.38(ii), with $[k^5]p_0 = 1$, $\mathsf{L}_0 = V_1 = 84$ (Definition 39.37, Proposition 39.35(ii), which allows the exponent 0 of K), $p_1(0) = -12$ and $p_2(0) = 720$:

$$84 - 12P(1) + 720P(2) = 0, \qquad P(2) = \frac{P(1) - 7}{60},$$

and every value lies in $\mathbb{Q} + \mathbb{Q}\,P(1)$, p_2 having no zero at $k \geq 0$.

The first bracket. Proposition 41.7(ii), with $a = 1$: $-aV_1/p_1(0) = 7$ and $-aV_1/\big(p_1(0) + f^\star p_2(0)\big) = -84/(-12 + \frac{720}{256}) = -84/(-\frac{147}{16}) = \frac{64}{7}$, both positive, so $7 < P(1) < \frac{64}{7}$.

The brackets. Let c and r solve the law with $(c(1), c(2)) = (1, \frac{1}{60})$, of low-end coefficient 0, and $(r(1), r(2)) = (0, -\frac{7}{60})$, of low-end coefficient 84; then $P(K) = c(K)P(1) + r(K)$ (Proposition 43.6(ii)):

K	1	2	3	4	5	6
$c(K)$	1	$\frac{1}{60}$	$\frac{1}{900}$	$\frac{47}{400400}$	$\frac{79}{5105100}$	$\frac{2273}{977728752}$
$r(K)$	0	$-\frac{7}{60}$	$-\frac{173}{21600}$	$-\frac{73219}{86486400}$	$-\frac{140653}{1260230400}$	$-\frac{3541028833}{211189410432000}$

Positivity at K (Proposition 41.4(i) with $p = 1$) and at $K-1$ with $p = f^\star - t$, where $c(K) > 0$ and $256c(K) - c(K-1) > 0$ (true for $2 \leq K \leq 90$), give

$$a_K = -\frac{r(K)}{c(K)} < P(1) < b_K = \frac{r(K-1) - 256\,r(K)}{256\,c(K) - c(K-1)};$$

$K = 2$ is the first bracket. The widths are 2.143, $1.297 \cdot 10^{-2}$, $1.513 \cdot 10^{-4}$, $2.042 \cdot 10^{-6}$ at $K = 2, \ldots, 5$, $3.50 \cdot 10^{-19}$ at $K = 12$ and $1.161 \cdot 10^{-33}$ at $K = 20$; the brackets are nested, and the ratio of consecutive widths, 0.01524 at $K = 10$ and 0.01562 at $K = 80$, tends to $\frac{1}{64} = f^\star/\lambda'$, $\lambda' = \frac{1}{4}$ (Theorem 41.3(iv)). At $K = 12$

$$\frac{125311627268888255929639}{17374611099178960704000} < P(1) < \frac{2909077508602860430922579 47}{40334717113590600816192000}.$$

The value. The roots $\frac{1}{256}$ and $\frac{1}{4}$ are distinct, the second outside the disc $|\lambda| \leq f^\star$, and p_0, p_2 have the largest degree 5 and no zero at $k \geq 1$: by Theorem 41.3(iii) the values are the minimal solution, and by (iv), with $x^{(0)} = r$ and $x^{(1)} = c$, the approximants are $M^{(K)} = a_K$. At $K = 90$, of width $4 \cdot 10^{-160}$, as a rendering,

$$P(1) = 7.21234141895756571239842896906869994458991775404299329075362\ldots,$$

and $P(2) = (P(1) - 7)/60$. The continued fraction of Proposition 41.7(iii), $\rho_1 = \mathsf{M}_1 \circ \cdots \circ \mathsf{M}_K(0)$ and $P(1) = -aV_1/(p_1(0) + p_2(0)\rho_1)$, gives the same number, to 20 places at depth 10 and to 39 at depth 40. □

54.10 Positivity against the gauge end

The centre ray of $\binom{[3]}{1}$ at the strength one has the stride $\big(K(\alpha)K(\alpha^{-1})\big)^{-1}$, $K=\alpha_1+\alpha_2+\alpha_3$, $V_1=3!=6$, and the values $P(k)=P_{\binom{[3]}{1}}(k\mathbf{1};k,k)$; $\ell=P(1)$. By Theorem 42.12 at $n=3$ its law is $s^2P(s)-(10s^2+10s+3)P(s+1)+9(s+1)^2P(s+2)=0$, of symbol $(1-\lambda)(1-9\lambda)$ with the roots $f^\star=\frac{1}{9}$ and 1 (Proposition 42.9), and the low-end relation (Corollary 39.38(ii)) is $6-3\ell+9P(2)=0$. So $P(K)=c(K)\,\ell+r(K)$ with $(c(1),c(2))=(1,\frac{1}{3})$ and $(r(1),r(2))=(0,-\frac{2}{3})$; the law is reflexive with the ratio $\frac{1}{9}$, and $c(K)=9^{1-K}\mathsf{C}_{K-1}(1)$ (Theorem 43.8(ii)), $\mathsf{C}_j(1)=1,3,15,93,639,4653,\dots$.

Exercise 54.19 (All positivity conditions on the centre of $\binom{[3]}{1}$)**.** (i) Read ℓ from the gauge end.

(ii) For $N\le 22$ compare the bracket of the two conditions $P(K)>0$, $P(K)<\frac{1}{9}P(K-1)$ at $K=N+1$ with the bracket of all positivity conditions of degree at most N at the strength 1 (Proposition 41.4), both read on $P(1),\dots,P(N+1)$.

(iii) Find the rate of the second (Theorem 41.5).

Solution. Receipt: `ex27_positivity.py`.

(i) *The gauge end.* $n=3$, $f^\star=\frac{1}{9}$, $\det H=(2\sigma)^2/K(\mathbf{1})^3=\frac{4}{27}$ (Proposition 42.9(ii)), so $g(0)=\frac{2\pi}{f^\star\sqrt{\det H}}=27\sqrt{3}\,\Gamma(\frac{1}{2})^2$ (Proposition 40.3(ii)). The density operator (Definition 40.4) is $a_0+a_1\partial_t+a_2\partial_t^2$ with $a_0=1-23t+36t^2$, $a_1=t(3-40t+45t^2)$, $a_2=t^2(t-1)(9t-1)$. At $\frac{1}{9}$, $b_{2,1}=\frac{8}{81}$, $\gamma=0=\frac{n-3}{2}$, $R_0=\frac{8}{81}x^2$, $R_1=-\frac{1}{9}(15x^2+23x+10)$, $R_2=(2x+3)(3x+5)$, $R_3=9(x+2)^2$: the exponents are 0 and $\gamma=0$, and the line is the holomorphic germ, $u_0=g(0)$ and $R_0(N)u_N=-\sum_{m=1}^{3}R_m(N-m)u_{N-m}$ (Theorem 40.6(iv)), so $u_r/u_0=1,\frac{45}{4},\frac{3645}{32},\frac{70713}{64},\frac{21500397}{2048}$ for $r\le 4$. The Beta sums at $K=200,201$ with 500 terms and the law run back give, as a rendering,

$$\ell=2.34390723868945889060156228887227706909540300963585626066630\dots;$$

the reading from $K=300$ agrees to 10^{-129}, and $3P(1)-9P(2)=6.000\dots$ returns V_1.

(ii) *The two conditions.* At $K=N+1$, $a_K=-r(K)/c(K)<\ell<b_K=\big(r(K-1)-9r(K)\big)/\big(9c(K)-c(K-1)\big)$: at $K=2$, $2<\ell<3$; at $K=3$, with $c(3)=\frac{5}{27}$ and $r(3)=-\frac{23}{54}$, $\frac{23}{10}<\ell<\frac{19}{8}$.

All conditions. By Proposition 41.4(ii) the conditions of degree at most N at the strength 1 are the positive semidefiniteness of the Hankel matrices $[P(1+i+i')]$, $[P(2+i+i')]$, $[\frac{1}{9}P(1+i+i')-P(2+i+i')]$ and $[\frac{1}{9}P(2+i+i')-P(3+i+i')]$ of the sizes allowed by N. Each is affine in ℓ; the set where one is positive semidefinite is an interval, its least eigenvalue being concave in ℓ, whose ends are the roots of its determinant nearest to a point where it is positive definite, such as the gauge-end ℓ. The determinants are computed exactly as polynomials in ℓ and their real roots isolated in ball arithmetic. At $N=1$ the conditions are $\frac{1}{3}\ell-\frac{2}{3}\ge 0$ and $\frac{2}{3}-\frac{2}{9}\ell\ge 0$: $2\le\ell\le 3$. At $N=2$ the binding ones are

$$\det\begin{bmatrix}P(1)&P(2)\\P(2)&P(3)\end{bmatrix}=\frac{4\ell^2+\ell-24}{54}\ge 0,\qquad \frac{1}{9}P(2)-P(3)=\frac{19}{54}-\frac{4}{27}\ell\ge 0,$$

so $\frac{\sqrt{385}-1}{8} \le \ell \le \frac{19}{8}$, of width $\frac{20-\sqrt{385}}{8} = 0.0473\ldots$. The widths:

N	two conditions	all conditions
1	1	1
2	$7.50 \cdot 10^{-2}$	$4.73 \cdot 10^{-2}$
4	$7.84 \cdot 10^{-4}$	$6.90 \cdot 10^{-5}$
8	$1.10 \cdot 10^{-7}$	$9.52 \cdot 10^{-11}$
12	$1.64 \cdot 10^{-11}$	$1.04 \cdot 10^{-16}$
16	$2.46 \cdot 10^{-15}$	$1.03 \cdot 10^{-22}$
22	$4.58 \cdot 10^{-21}$	$9.10 \cdot 10^{-32}$

and the ratio of the widths of all conditions at N and $N-1$ is 0.0382, 0.0335, 0.0320, 0.0314, 0.0308 at $N = 4, 8, 12, 16, 22$. Every bracket contains the gauge-end ℓ.

(iii) *The rate.* The free direction is $u = c$. By Proposition 40.12(i), $\mathsf{C}_j(1) = \int t^{-j} \nu_f^{\mathbb{T}}(dt)$, the torus law (Definition 40.11) being carried by $[\frac{1}{9}, \infty)$; with $\tau = 1/(9t)$, $c(K) = \int_0^1 \tau^K \nu(\tau)\, d\tau$, $\nu(\tau)$ being τ^{-1} times the density of the image of $\nu_f^{\mathbb{T}}$, and by Proposition 40.12(iii) $\nu(\tau) \to \frac{1}{9} \cdot \frac{g(0)}{(2\pi)^2} = \frac{3\sqrt{3}}{4\pi} \neq 0$ as $\tau \uparrow 1$: the exponent $a = 0$ of Theorem 41.5 at $\lambda = 1$. With $w = 2\lambda/f^\star - 1 = 17$ the bracket of degree N has length at most $C\, N\, e^{-N g(1)}$,

$$e^{-g(1)} = \frac{1}{17 + \sqrt{288}} = 17 - 12\sqrt{2} = 0.02943\ldots,$$

against the factor $\frac{1}{9}$ per step of the two conditions (Theorem 41.3(iv)): $-\log_{10}(17 - 12\sqrt{2}) = 1.531$ digits of ℓ per value against $\log_{10} 9 = 0.954$. The ratios of the table approach $17 - 12\sqrt{2}$ from above, as the factor N allows; with the nine values $P(1), \ldots, P(9)$ all conditions give ℓ to 10^{-10}, the two conditions to 10^{-7}. □

54.11 What the closings see

Exercise 54.20 (What the closings see at small centres)**.** Take the following lists, with unit weights, on the marks $[n] = \{1, \ldots, n\}$: the lists $\binom{[n]}{1}$, $n = 3, 4, 5$, whose bases are the single marks; the list H_4 on [4], whose bases are the pairs other than $\{1, 2\}$; the wheel W_3 of Proposition 39.65, whose marks are the six edges $e_1 = 01$, $e_2 = 02$, $e_3 = 03$, $e_4 = 12$, $e_5 = 13$, $e_6 = 23$ of the complete graph on the vertices $0, 1, 2, 3$ and whose bases are its sixteen spanning trees; the list N_6 on [6], whose bases are the nineteen triples other than $\{1, 2, 3\}$; and the uniform lists $\binom{[5]}{2}$ and $\binom{[6]}{3}$. Read each on its centre ray at the strength 1 (Definition 38.13), with origin 0, direction $(\mathbf{1}; 1, 1)$ and stride $f = \alpha^{\mathbf{1}}(K\Psi)^{-1}$, and read H_4 also on the ray with origin 0 and direction $(1, 1, 3, 3; 3, 1)$. Let G be generated by the automorphisms that keep the masses and, at a centre, the Cremona, with the exchanges where they are named. For a box accepted at $\mathfrak{s}$ (Definition 39.20), with the spanning set $\mathbf{b} = (b_1, \ldots, b_{\mathfrak{m}})$, $b_1 = 1$, and the matrix $\mathbf{B}$, write $\mathbf{B} = P_0/Q_0$ with Q_0 the monic least common denominator of its entries, $D_0 = \max(\deg P_0, \deg Q_0)$, and let $\mathcal{S}_D$ be the space of the pairs (P, Q) of a matrix and a scalar of polynomials of degree at most D with $Q(-j)\, \mathsf{C}_{j+1}(\mathbf{b}) = P(-j)\, \mathsf{C}_j(\mathbf{b})$ for all large j, the closing equations of Proposition 39.61.

(i) At the centres of $\binom{[3]}{1}$, $\binom{[4]}{1}$, $\binom{[5]}{1}$, H_4, W_3, with and without its exchanges, and N_6 with its exchanges, and on the ray $(1, 1, 3, 3; 3, 1)$ of H_4, show that $\dim \mathcal{S}_D = 0, 1, 2, 3$ at $D = D_0 - 1, \ldots, D_0 + 2$, the line at D_0 being spanned by (P_0, Q_0), and find a degree up to which no element of the span of $\mathbf{b}$ with polynomial coordinates is annihilated by the closings. Work the centre of $\binom{[3]}{1}$ in full.

(ii) At the centre of N_6, with G generated by the automorphisms and the Cremona but not the exchanges, show that the closings miss a nonzero submodule of the span of the spanning set.

(iii) At the centre of $\binom{[5]}{2}$, with every symmetry of the four kinds in G: find the native gauges; show that the spanning set of the box $\mathfrak{B}_3(1,1)$ at $\mathfrak{s}=2$ is a set of masters of its span $\mathfrak{N}$; show that $\mathfrak{N}$ is the direct sum of the cyclic submodule of [1] and a line L on which the closings, the values and $A_\star$ vanish, reading $\binom{[5]}{2}$ as the contraction of $\binom{[6]}{3}$ (Proposition 39.62); find which solutions at the native gauges see L; and read the centre of $\binom{[6]}{3}$ by its box.

Solution. Every ray here has origin 0, positive letter exponents and positive walls, so Definition 39.30, Theorem 39.33, Proposition 39.34 and Theorem 39.57 apply. Three facts are used throughout.

(a) If an element $m=\sum_l p_l(k)[b_l]$ with polynomial coefficients has values that vanish identically, then $\sum_l p_l(-j)\,\mathsf{C}_j(b_l)=0$ for every $j\ge 0$, not only for large j: the b_l are Laurent insertions, so their closings are defined from $j=0$ on, and Proposition 39.34 gives $V_1\sum_l p_l(-j)\mathsf{C}_j(b_l)=\lim_{k\to -j}(k+j)^{n-1}\langle m\rangle_k=0$. This holds for the elements of $\mathcal{L}$ (Proposition 38.5(ii)) and for the elements on which the closings vanish (Theorem 39.57). The box gives $Q_0(k)\big(f^{-1}b_i-\sum_l \mathbf{B}_{il}(k)\,b_l\big)\in\mathcal{L}$ (Theorem 39.21(i)), and $\mathsf{C}_j(f^{-1}b_i)=\mathsf{C}_{j+1}(b_i)$, so

$$\mathsf{C}_{j+1}(\mathbf{b})=\mathbf{B}(-j)\,\mathsf{C}_j(\mathbf{b})\qquad\text{for every } j\ge 0 \text{ with } Q_0(-j)\neq 0.$$

(b) By (a), $(P,Q)\in\mathcal{S}_D$ exactly when every row of $Q\mathbf{B}-P$, read as an element of the span of $\mathbf{b}$, is annihilated by the closings; Q_0 times such a row is a polynomial row p with $p(-j)\cdot\mathsf{C}_j(\mathbf{b})=0$ for every $j\ge 0$, so every pair of $\mathcal{S}_D$ satisfies its equation at every $j\ge 0$ with $Q_0(-j)\neq 0$. The equations at finitely many such j cut out a space that contains $\mathcal{S}_D$, and so does that system reduced modulo a prime, whose rank is at most its rank over $\mathbb{Q}$. The pairs (cP_0,cQ_0), $\deg c\le D-D_0$, lie in $\mathcal{S}_D$. So when a computed dimension is $\max(0,D-D_0+1)$, it is $\dim\mathcal{S}_D$.

(c) Likewise the polynomial rows of degree at most e that the closings annihilate at finitely many j contain the coordinate rows, of degree at most e, of the elements of the span of $\mathbf{b}$ on which the closings vanish.

(i) The centre of $\binom{[3]}{1}$. The letters are $K=\alpha_1+\alpha_2+\alpha_3$ and $\Psi=\alpha_1\alpha_2+\alpha_1\alpha_3+\alpha_2\alpha_3$, and

$$f^{-1}=\frac{K\Psi}{\alpha_1\alpha_2\alpha_3}=3+\sum_{i\neq j}\frac{\alpha_i}{\alpha_j}.$$

For a nonempty proper U, $d(U)=0$ and $d^*(U)=|U|-1$, so every wall of the direction is $\kappa_{1,U}=1$ and the wall degree of α^u is $\max_U(-u_U)$ (Definition 39.15(ii)). G is generated by the six bijections of [3] and the Cremona; it holds every symmetry of the four kinds, the list having no exchange (its bases have one mark, its cobases two). The box $\mathfrak{B}_2(1,1)$ has 110 symbols; modulo G its relations, taken at one symbol of each orbit, are 26 combinations of 16 orbit averages, of rank 13 over $\mathbb{Q}(k)$ (receipts `boxexact.py`, `boxes_all.py`, exact elimination over $\mathbb{Z}[k]$). The free orbits are those of 1, of α_3/α_1, of wall degree 1, and of $(\mathbf{1};1,1)$, at a positive level; so at $\mathfrak{s}=1$ the spanning set is $b_1=1$, $b_2=e_G(\alpha_3/\alpha_1)=\frac{1}{6}\sum_{i\neq j}\alpha_i/\alpha_j$, both targets reduce to it, and

$$\mathbf{B}(k)=\begin{bmatrix}3 & 6\\ \dfrac{2(k-1)}{k-2} & \dfrac{(k-1)(7k-11)}{(k-2)^2}\end{bmatrix},$$

with $Q_0=(k-2)^2$ and

$$P_0=\begin{bmatrix}3(k-2)^2 & 6(k-2)^2\\ 2(k-1)(k-2) & (k-1)(7k-11)\end{bmatrix},$$

so $D_0 = 2$; the first row is the Laurent identity $f^{-1}b_1 = 3b_1 + 6b_2$.

The native gauge of the direction, $\mathbf{1}$, has the native value $\frac{1}{9}$, and the three signs with one scale -1 have $K(\eta) = 1$, so they are native gauges of the native value 1 (Theorem 38.17(ii)); on a chart $\det(-H) = \frac{4}{27}$ at $\mathbf{1}$ and -4 at the signs (receipt `signs_span.py`), so all four are nondegenerate. Their solutions, summed over the two orbits, have distinct types and do not vanish at [1], so the span $\mathfrak{N}$ of b_1, b_2 has dimension 2 (Lemma 39.3): $\mathbf{b}$ is a set of masters and $\mathbf{B} = \mathbf{B_b}$. The rows $w_0 = (1, 0)$ and $w_1 = (3, 6)$ are independent, so $\mathfrak{N}$ is the cyclic submodule of [1] (Proposition 39.6(ii)).

The closings are the constant terms $\mathsf{C}_j(b) = \mathrm{CT}(b\, f^{-j})$; $\mathsf{C}_j(1)$ is the coefficient of $\alpha_1^j\alpha_2^j\alpha_3^j$ in $(K\Psi)^j$. By direct expansion,

j	0	1	2	3	4	5	6	7	8
$\mathsf{C}_j(b_1)$	1	3	15	93	639	4653	35169	272835	2157759
$\mathsf{C}_j(b_2)$	0	1	8	60	456	3535	27888	223209	1807760

for instance $\mathsf{C}_1(b_2) = \mathrm{CT}\left(b_2(3 + 6b_2)\right) = 6 \cdot \frac{6}{36} = 1$, the six products $\frac{\alpha_i}{\alpha_j}\frac{\alpha_j}{\alpha_i}$ in b_2^2 being the only constant ones. Q_0 has no zero at a nonpositive integer, so (a) gives $\mathsf{C}_{j+1} = \mathbf{B}(-j)\,\mathsf{C}_j$ for every $j \geq 0$: at $j = 1$ and $j = 2$,

$$\mathbf{B}(-1) = \begin{bmatrix} 3 & 6 \\ \frac{4}{3} & 4 \end{bmatrix}, \quad \mathbf{B}(-1)\begin{bmatrix} 3 \\ 1 \end{bmatrix} = \begin{bmatrix} 15 \\ 8 \end{bmatrix}; \qquad \mathbf{B}(-2) = \begin{bmatrix} 3 & 6 \\ \frac{3}{2} & \frac{75}{16} \end{bmatrix}, \quad \mathbf{B}(-2)\begin{bmatrix} 15 \\ 8 \end{bmatrix} = \begin{bmatrix} 93 \\ 60 \end{bmatrix},$$

and the direct expansion agrees for every $j \leq 79$ (receipt `three_exact.py`).

The closing equations at the degree D have $5(D + 1)$ unknowns, the coefficients of the four entries of P and of Q, and two equations for each j. With $1 \leq j \leq 79$, 158 equations, exact elimination over $\mathbb{Q}$ gives the solution dimensions $0, 1, 2, 3$ at $D = 1, 2, 3, 4$; by (b) these are $\dim \mathcal{S}_D$, and the line at $D = 2$ is spanned by (P_0, Q_0). So the closings alone single out $\mathbf{B_b}$ among the matrices of degree at most 2, with no source supplied. The rows (p_1, p_2) of degree at most 24 with $p_1(-j)\mathsf{C}_j(b_1) + p_2(-j)\mathsf{C}_j(b_2) = 0$ for $1 \leq j \leq 80$, 50 unknowns and 80 equations, are only 0; by (c), no nonzero element of $\mathfrak{N}$ with polynomial coordinates of degree at most 24 is annihilated by the closings.

(i) The other rays. The same computation runs on the other boxes (receipt `blind2.py`, driven by `run_blind2.sh`): the closings at $j \leq 7$ are read on the torus as constant terms and continued by (a), and the equations are reduced modulo the prime $2^{61} - 1$; by (b) and (c) the dimensions found are upper bounds, attained here. The matrices $\mathbf{B}$ are those of the boxes built from Definition 39.15 and eliminated exactly over $\mathbb{Q}(k)$ (receipt `boxes_all.py`); at N_6 they are the rayreader's, checked against an elimination of the whole box at a random prime and strength. The spanning sets, with exponents in the order of the marks, are: $1, e_G(\alpha_4/\alpha_1)$ for $\binom{[4]}{1}$; $1, e_G(\alpha_5/\alpha_1), e_G(\alpha_5^2/\alpha_1^2)$ for $\binom{[5]}{1}$; $1, e_G\alpha^u$ with $u = (-1,0,0,1), (-1,1,-1,1), (-1,1,0,0)$ for H_4 at its centre, and $u = (0,1,-1,0), (0,2,-2,0), (0,2,-1,-1)$ on its ray $(1,1,3,3;3,1)$; $1, e_G\alpha^u$ with $u = (-1,-1,0,0,1,1), (-1,-1,0,1,0,1), (-1,-1,1,1,-1,1), (-1,-1,1,1,0,0)$ for W_3, with or without the exchanges; and for N_6 with its exchanges $1, e_G\alpha^u$ with the twelve $u = (-1,-1,0,0,1,1)$, $(-1,-1,1,-1,1,1)$, $(-1,-1,1,0,0,1)$, $(-1,0,0,0,0,1)$, $(-1,0,1,-1,0,1)$, $(-1,0,1,0,0,0)$, $(-1,-1,-1,1,1,1)$, $(-2,-2,0,0,2,2)$, $(-2,-2,0,1,1,2)$, $(-2,-2,1,-1,2,2)$, $(-2,-2,1,0,1,2)$, $(-2,-2,1,1,1,1)$. In the table, $\dim \mathcal{S}_D$ is listed at $D = D_0 - 1, \ldots, D_0 + 2$, h is the first index at which the rows $w_0, \ldots, w_h$ of [1] are dependent (Proposition 39.6(ii)), and the last but one column gives the degree up to which no nonzero row is annihilated, at the j from 10 to the bound shown.

ray	$\lvert G\rvert$	box, $\mathfrak{s}$	$\mathfrak{m}$	D_0	$\dim \mathcal{S}_D$	rows	h
$\binom{[4]}{1}$	48	$(2;1,1)$, 1	2	3	$0,1,2,3$	24, $j \le 120$	2
$\binom{[5]}{1}$	240	$(3;1,1)$, 2	3	6	$0,1,2,3$	24, $j \le 120$	3
H_4	8	$(2;1,1)$, 1	4	3	$0,1,2,3$	24, $j \le 150$	4
H_4, $(1,1,3,3;3,1)$	4	$(2;1,1)$, 1	4	10	$0,1,2,3$	24, $j \le 150$	4
W_3	48, 96	$(2;1,1)$, 1	5	9	$0,1,2,3$	40, $j \le 260$	4
N_6, exchanges	144	$(3;1,1)$, 2	13	16	$0,1,2,3$	32, $j \le 480$	11

The denominators are $Q_0 = (k-2)^3$, $(k-3)^4$, $(k-2)^3$, $k(k-1)^3(k-\frac{4}{3})^3(k-\frac{5}{3})^3$, $(k-2)^5(k-\frac{3}{2})(k^3-3k^2+\frac{3}{2}k+2)$, and for N_6 a polynomial of degree 16 with the factors $(k-4)(k-3)^5(k-2)^3(k-\frac{5}{2})$ and an irreducible sextic; only that of the ray $(1,1,3,3;3,1)$ vanishes at a nonpositive integer, at $k=0$, below the j used. At $\binom{[4]}{1}$ the native gauges $\mathbf{1}$ and the four signs with one scale -1, of the native values $\frac{1}{16}$ and $\frac{1}{4}$, and at $\binom{[5]}{1}$ the native gauges $\mathbf{1}$ and the signs with one and with two scales -1, of the native values $\frac{1}{25}$, $\frac{1}{9}$ and 1, are nondegenerate (receipt `signs_span.py`), so by Lemma 39.3 their spanning sets are sets of masters. At H_4, W_3 and N_6 the signs of the largest native value are degenerate native gauges, and the computations are read for the spanning set as it stands; then h bounds the dimension of the cyclic submodule of [1] from above. At each of these rays the closings alone single out the box's matrix among the matrices of degree at most D_0; at W_3 and at N_6 the rows of [1] become dependent before the size of the spanning set is reached, and the closings single out the whole matrix on the spanning set, not only the law that the rows of [1] give.

(ii) N_6 *without the exchanges.* Now $\lvert G\rvert = 72$, and the box $\mathfrak{B}_3(1,1)$ is accepted at $\mathfrak{s}=2$ with 15 elements: the thirteen above, here averaged over the smaller group, and $e_G\alpha^u$ for $u = (-1,0,0,-1,1,1)$ and $(-2,-2,2,-2,2,2)$. The bijection x with $x(i) = i+3$ and $x(i+3) = i$, $i \le 3$, carries the bases, the triples other than $\{1,2,3\}$, onto the complements of the bases, the triples other than $\{4,5,6\}$: it exchanges the list, and at the centre it is a symmetry of the ray (Proposition 39.11(ii)). With G_x generated by G and x, G is normal of index 2 in G_x, and for $b = e_G\alpha^{(-1,-1,1,0,0,1)}$, an element of the spanning set, $x^*b = e_G\alpha^{(-1,0,0,-1,1,1)}$, another (receipt `n_exchange.py`); so $(1-e_{G_x})b = \frac{1}{2}(b-x^*b)$, on which the closings, the values and $A_\star$ vanish (Corollary 39.59, applied to G_x). It is not 0: at the sign η with the scales -1 on $\{4,5\}$, $K(\eta) = -5$, a nondegenerate native gauge of the native value $\frac{1}{25}$ with $\det(-H) = -\frac{9216}{15625}$ on a chart, $b(\eta) = -\frac{1}{3}$ and $x^*b(\eta) = 1$, so the leading coefficient of $A_\eta(b-x^*b)$ is $-\frac{4}{3}$ times that of $A_\eta(1)$ (Theorem 38.6(i)). So the closings miss the nonzero submodule generated by $b-x^*b$, the part of the span that the exchanges negate. The computation of (i) agrees: the rows of degree at most e annihilated at $10 \le j \le 400$ have the dimension $e+1$ for $e \le 8$, so by (c) they are exactly the multiples $p(k)(b-x^*b)$, $\deg p \le e$; and the solution spaces of the closing equations at $D = 17,18,19,20$ have dimensions at most $400, 431, 462, 493$, growing by $31 = 15\cdot 2+1$, the slope of Proposition 39.61 for a missed submodule of dimension two.

(iii) The centre of $\binom{[5]}{2}$. Here $K = e_2$, $\Psi = e_3$, $f^{-1} = e_2e_3/(\alpha_1\cdots\alpha_5)$, and G is generated by the bijections of [5] and the Cremona, $\lvert G\rvert = 240$: the list has no exchange, its bases having two marks and its cobases three, so this is every symmetry of the four kinds.

The native gauges. On the chart $\alpha_5 = 1$ the defects times e_2e_3 generate an ideal whose saturation by the scales and the letters is zero-dimensional and radical of degree 66 (receipt `u25.sing`, an exact Gröbner basis computation): there are 66 native gauges, all simple zeros of the defects and so nondegenerate. Five points, checked exactly to be native gauges (receipt `u25_core.py`),

and their orbits under G account for all 66; with $\zeta = e^{2\pi i/3}$ and the spanning set $\mathbf{b}$ found below,

point	native value	orbit	$(b_1,\dots,b_5)$ at the point
$\mathbf{1}$	$\frac{1}{100}$	1	$(1,1,1,1,1)$
$(1,1,1,1,-1)$	$\frac{1}{4}$	5	$(1,-\frac{3}{5},\frac{1}{5},1,\frac{1}{5})$
$(1,1,1,-1,-1)$	$\frac{1}{4}$	10	$(1,\frac{1}{5},-\frac{1}{5},1,-\frac{1}{5})$
$(\sqrt{3}-2,\sqrt{3}-2,\sqrt{3}-2,1,1)$	$-\frac{1}{8}$	20	$(1,1,-\frac{4}{5},\frac{113}{5},\frac{23}{5})$
$(1,1,\zeta,\zeta,\zeta^2)$	1	30	$(1,\frac{1}{10},-\frac{1}{5},\frac{1}{10},-\frac{1}{5})$

On the chart $\det(-H)$ is $\frac{81}{3125}$, -3, -3, $-\frac{81}{16}$ and 81 at these points. The orbits are the table's gauge, the signs with one and with two scales -1, the points with three scales $\sqrt{3}-2$ and two scales 1 or two and three, which the Cremona joins, and the points with two scales 1, two ζ and one ζ^2.

The box. The box $\mathfrak{B}_3(1,1)$ has 10322 symbols; modulo G its relations at the orbit representatives are 196 combinations of 114 orbit averages, of rank 103, eliminated exactly over $\mathbb{Q}(k)$. The free Laurent orbits of wall degree at most 2 give the spanning set

$$b_1 = 1, \qquad b_2 = e_G\alpha^{(-1,-1,0,1,1)}, \qquad b_3 = e_G\frac{\alpha_5}{\alpha_1} = \frac{1}{20}\sum_{i\neq j}\frac{\alpha_i}{\alpha_j},$$
$$b_4 = e_G\alpha^{(-2,-2,0,2,2)}, \qquad b_5 = e_G\alpha^{(-2,-2,1,1,2)},$$

of wall degrees $0,1,1,2,2$, and the box is accepted at $\mathfrak{s}=2$. With $q(k) = 3k^3+4k^2-61k+130$, its matrix has the rows $\mathbf{B}_{1\bullet} = (10,30,60,0,0)$, the Laurent identity $f^{-1} = 10b_1+30b_2+60b_3$, and

$$\tfrac{q}{k-1}\mathbf{B}_{2\bullet} = \Big(27k^2+111k-130,\ \tfrac{2(51k^3+137k^2-756k+580)}{k-2},\ \tfrac{16(9k^3+33k^2-155k+108)}{k-2},$$
$$-3(3k^2-9k-10),\ 12(3k^2-k+2)\Big),$$
$$\tfrac{q}{k-1}\mathbf{B}_{3\bullet} = \Big(6(5k^2+8k-65),\ \tfrac{6(15k^3+6k^2-313k+440)}{k-2},\ \tfrac{4(33k^3+74k^2-971k+1340)}{k-2},$$
$$-12(k-5)(k-2),\ 12(5k^2-14k+5)\Big),$$

$$\tfrac{q\,(k-3)^4}{k-1}\mathbf{B}_{41} = k(27k^5+245k^4-1789k^3+3709k^2-5388k+5820),$$
$$\tfrac{q\,(k-3)^4}{k-1}\mathbf{B}_{42} = \tfrac{2(45k^7+225k^6-2310k^5+3606k^4+1139k^3-157k^2-7152k+2460)}{k-2},$$
$$\tfrac{q\,(k-3)^4}{k-1}\mathbf{B}_{43} = \tfrac{4(216k^7-552k^6-925k^5-1703k^4+18473k^3-28953k^2+33288k-33444)}{3(k-2)},$$
$$\tfrac{q\,(k-3)^4}{k-1}\mathbf{B}_{44} = 3k^6-283k^5+3037k^4-13753k^3+33126k^2-43566k+25020,$$
$$\tfrac{q\,(k-3)^4}{k-1}\mathbf{B}_{45} = -4(k-2)(27k^5-373k^4+1321k^3-1507k^2-450k+1878),$$
$$\tfrac{q\,(k-3)^3}{k-1}\mathbf{B}_{51} = 2k(15k^4+52k^3-232k^2+153k-420),$$
$$\tfrac{q\,(k-3)^3}{k-1}\mathbf{B}_{52} = \tfrac{2(45k^6+111k^5-963k^4+461k^3+936k^2+478k-540)}{k-2},$$
$$\tfrac{q\,(k-3)^3}{k-1}\mathbf{B}_{53} = \tfrac{4(117k^6+225k^5-2281k^4+1565k^3+1564k^2-1562k+5028)}{3(k-2)},$$
$$\tfrac{q\,(k-3)^3}{k-1}\mathbf{B}_{54} = -2(6k^5-17k^4-185k^3+1052k^2-2368k+2280),$$
$$\tfrac{q\,(k-3)^3}{k-1}\mathbf{B}_{55} = 4(9k^5+32k^4-250k^3+412k^2-65k-522),$$

so $Q_0 = (k-3)^4(k-2)\,q(k)/3$ and $D_0 = 8$; it equals the rayreader's matrix.

Masters. The five orbit sums of the solutions A_c (Theorem 39.12(iii)) have the types $\frac{1}{100}, \frac{1}{4}, \frac{1}{4}, -\frac{1}{8}, 1$. Those alone in their type do not vanish at [1]. On b_1, b_2 the two of the type $\frac{1}{4}$ have the leading coefficients $5C(1, -\frac{3}{5})$ and $10C'(1, \frac{1}{5})$, $C, C' \neq 0$, and $\det \begin{bmatrix} 1 & -\frac{3}{5} \\ 1 & \frac{1}{5} \end{bmatrix} = \frac{4}{5} \neq 0$, so they are linearly independent on $\mathfrak{N}$. By Lemma 39.3, $\dim \mathfrak{N} \geq 5$: the spanning set is a set of masters of $\mathfrak{N}$, of dimension exactly 5, and $\mathbf{B} = \mathbf{B_b}$. The five rows of values in the table have the determinant $\frac{3888}{625}$, so $\mathbf{B}(\infty)$ is diagonalizable with the eigenvalues $100, 4, 4, -8, 1$ (Proposition 39.42(i), (ii)); indeed

$$\mathbf{B}(\infty) = \begin{bmatrix} 10 & 30 & 60 & 0 & 0 \\ 9 & 34 & 48 & -3 & 12 \\ 10 & 30 & 44 & -4 & 20 \\ 9 & 30 & 96 & 1 & -36 \\ 10 & 30 & 52 & -4 & 12 \end{bmatrix}, \qquad \det(\lambda - \mathbf{B}(\infty)) = (\lambda - 100)(\lambda - 4)^2(\lambda + 8)(\lambda - 1)$$

(receipt `binf_exact.py`).

The law and the line. The rows $w_i(k) = w_{i-1}(k-1)\mathbf{B}(k)$, $w_0 = (1, 0, 0, 0, 0)$, are independent for $i \leq 3$ and dependent at $i = 4$, so the cyclic submodule $\mathfrak{N}_1$ of [1] has dimension 4 and the law of [1] (Proposition 39.6(ii)) is $\sum_{j=0}^{4} p_j(k)\,\mathrm{Sh}^j[1] = 0$ with

$$\begin{aligned} p_0 &= k^4(33k^2 + 88k + 60), \\ p_1 &= -(3201k^6 + 14938k^5 + 27699k^4 + 26214k^3 + 13598k^2 + 3736k + 440), \\ p_2 &= -4(2772k^6 + 18480k^5 + 48699k^4 + 63150k^3 + 40515k^2 + 11296k + 1140), \\ p_3 &= 16(k+2)^2(7491k^4 + 34958k^3 + 51724k^2 + 24507k + 4430), \\ p_4 &= -3200(k+2)^2(k+3)^2(33k^2 + 22k + 5). \end{aligned}$$

Put

$$\begin{aligned} m = {} & k(k-5)(k-2)(k+2)\,[b_1] - (3k^4 + 11k^3 - 71k^2 + 227k - 210)\,[b_2] \\ & - \tfrac{2}{3}(3k^4 - 11k^3 + 119k^2 - 125k - 90)\,[b_3] - (k-5)(k-2)^3\,[b_4] + (k-2)^2(5k^2 - 14k + 5)\,[b_5] \end{aligned}$$

and $\tilde{m} = \frac{k-1}{q(k)}\,m$. With $\tilde{w}$ the coordinate row of $\tilde{m}$, the identity $\tilde{w}(k-1)\mathbf{B}(k) = 4\,\tilde{w}(k)$ holds exactly, that is $\mathrm{Sh}^{-1}\,\tilde{m} = 4\tilde{m}$, so $L = \mathbb{C}(k)\tilde{m}$ is a submodule; and at $k = \frac{37}{3}$ the rows $w_0, \ldots, w_3, \tilde{w}$ have rank 5. So

$$\mathfrak{N} = \mathfrak{N}_1 \oplus L.$$

The table one mark larger. $\binom{[5]}{2}$ is the contraction at the mark 6 of $\binom{[6]}{3}$, which is connected and identically self-dual, so Proposition 39.62 applies, with G' generated by the T_β, β a bijection of [6], and the Cremona, and $G \subseteq G'$. The native gauges lift by $\alpha_6 = \Psi/K$: the five points of the table to $\alpha_6 = 1, -1, 1, 1, \zeta^2$ (receipt `u36_lift.py`). The lifts are native gauges of the centre of $\binom{[6]}{3}$, which has 66 of them, all simple (receipt `u36.sing`), in orbits of S_6 and the Cremona of $1, 15, 20, 30$ points with the native values $\frac{1}{400}, \frac{1}{16}, -\frac{1}{32}, \frac{1}{4}$, a quarter of those below them: the two kinds of signs lift into one orbit of 15, the signs of $\binom{[6]}{3}$ with two scales -1, and this is Proposition 39.64(ii) at $r = 2$, with $C_2 = 2$.

The element ℓ. Put $S = \sum_{i \neq j \leq 5} \alpha_i/\alpha_j = 20\,b_3$ and $T = \frac{K}{\Psi}\sum_i \alpha_i + \frac{\Psi}{K}\sum_i \alpha_i^{-1}$. Since S is invariant under G, the image of the stabilizer of the mark 6, and the transpositions $(e\,6)$, $e \leq 5$,

with the identity, represent its cosets, $e_{G'}[S] = \frac{1}{6}\big([S] + \sum_{e\le 5} T_{(e\,6)}[S]\big)$. By Proposition 39.62(iii), with $\frac{\Gamma(k+1)\Gamma(k-1)}{\Gamma(k)^2} = \frac{k}{k-1}$,

$$T_{(e\,6)}\Big[\frac{\alpha_i}{\alpha_j}\Big] = \Big[\frac{\alpha_i}{\alpha_j}\Big]\ (e \notin \{i,j\}), \qquad \frac{k}{k-1}\Big[\frac{\Psi}{K\alpha_j}\Big]\ (e=i), \qquad \frac{k}{k-1}\Big[\frac{K\alpha_i}{\Psi}\Big]\ (e=j).$$

Each pair (i,j) is left alone by three of the five e, and each α_j^{-1} and each α_i arises four times, so $\sum_e T_{(e\,6)}[S] = 3[S] + \frac{4k}{k-1}[T]$, $e_{G'}[S] = \frac{2}{3}[S] + \frac{2k}{3(k-1)}[T]$, and

$$\ell = 3(1-e_{G'})[S] = [S] - \frac{2k}{k-1}\,[T].$$

The symbols of T, at the levels $(0,1)$ and $(1,0)$ and of wall degrees 0 and 1, lie in the box, which reduces T to the spanning set (receipt `u25_core.py`):

$$[T] = \frac{10(k-1)}{k}\,[b_3] - \frac{10}{k\,q(k)}\,m.$$

So

$$\ell = 20[b_3] - \frac{2k}{k-1}\Big(\frac{10(k-1)}{k}[b_3] - \frac{10}{k\,q(k)}m\Big) = \frac{20}{(k-1)\,q(k)}\,m = \frac{20}{(k-1)^2}\,\tilde{m}.$$

Since $e_{G'}(1-e_{G'}) = 0$, $e_{G'}\ell = 0$, hence $e_{G'}\tilde{m} = 0$ and $L \subseteq (1-e_{G'})\mathfrak{M}^G$: the closings, the values and $A_\star$ vanish on L (Proposition 39.62(iv)). The values can be seen to vanish directly as well: by the formula for π_* in Proposition 39.62, $\pi_*(\alpha_i/\alpha_6) = \frac{k}{k-1}\frac{K}{\Psi}\alpha_i$ and $\pi_*(\alpha_6/\alpha_i) = \frac{k}{k-1}\frac{\Psi}{K}\alpha_i^{-1}$, so $\ell = \pi_*\ell'$ with $\ell' = \sum_{i\ne j\le 5}\frac{\alpha_i}{\alpha_j} - 2\sum_{i\le 5}\big(\frac{\alpha_i}{\alpha_6} + \frac{\alpha_6}{\alpha_i}\big)$, three times the part of $\sum_{i\ne j\le 5}\alpha_i/\alpha_j$ that the average over the bijections of [6] removes; the values of $\binom{[6]}{3}$ are kept by those bijections (Proposition 39.11(ii)), so $\langle \ell'\rangle'_k = 0$ and $\langle \ell\rangle_k = \Gamma_{\!2\,1}\!\begin{bmatrix} k,\ k \\ 2k \end{bmatrix}^{-1}\langle \ell'\rangle'_k = 0$ (Proposition 39.62(i)). As a numerical check, a trapezoidal quadrature over the chart gives $|\langle \ell\rangle_k|/\langle 1\rangle_k$ equal to $1.0\cdot 10^{-13}$ at $k = \frac{13}{2}$ and $2.8\cdot 10^{-13}$ at $k = 8$, the accuracy of the quadrature (receipt `ell_check.py`). So L is a relation among the values of the five masters that the relations of the ray do not produce, m being nonzero in $\mathfrak{N}$, nor its symmetries of the four kinds, m lying in $\mathfrak{M}^G$.

What sees L. A solution V of the type $(\lambda, \rho+\mathbb{Z})$ has $\varsigma^{-1}V(\tilde{m}) = V(\mathrm{Sh}^{-1}\tilde{m}) = 4V(\tilde{m})$, which forces $V(\tilde{m}) = 0$ unless $\lambda^{-1} = 4$: the solutions at the orbits of the native values $\frac{1}{100}$, $-\frac{1}{8}$ and 1 vanish on L. At a sign, $A_c(b_l)/A_c(1) = b_l(\alpha_c) + O(1/k)$ (Theorem 38.6(i)), and the coefficients of k^4 in m are $(1,-3,-2,-1,5)$, so $A_c(m)/A_c(1)$ begins with

$$\big(1+\tfrac{9}{5}-\tfrac{2}{5}-1+1\big)k^4 = \tfrac{12}{5}k^4 \quad (\text{one scale } -1), \qquad \big(1-\tfrac{3}{5}+\tfrac{2}{5}-1-1\big)k^4 = -\tfrac{6}{5}k^4 \quad (\text{two scales } -1):$$

the solutions at both kinds of signs see L. With the solutions at the fifteen signs transported from one of them by G' as in Proposition 39.64(i), $A_c(1)$ is the same for all fifteen, $T_\gamma[1] = [1]$; their sum, invariant under G', has on m the leading coefficient $5\cdot\frac{12}{5} - 10\cdot\frac{6}{5} = 0$ times that of $A_c(1)$, as it must, while the mean over the five less the mean over the ten has $\frac{12}{5} + \frac{6}{5} = \frac{18}{5}$ and sees L.

The closings. The rows of degree at most e annihilated by the closings at $10 \le j \le 150$ have the dimension $\max(0, e-3)$ for $e \le 24$, which is the dimension of the multiples $p(k)\,w_m$, $\deg p \le e-4$, of the primitive coordinate row w_m of $3m$, of degree 4; by (c) the closings annihilate L and no element of $\mathfrak{N}$ outside L with polynomial coordinates of degree at most 24. The solution spaces of the closing equations at $D = 7, 8, 9, 10$ have dimensions at most $24, 30, 36, 42$, growing

by $6 = 5 \cdot 1 + 1$, the slope of Proposition 39.61 for a missed line; a step of more than one already shows that something is missed.

The centre of $\binom{[6]}{3}$ *by its box.* Modulo S_6 and the Cremona, of order 1440, the box $\mathfrak{B}_3(1,1)$, with 78296 symbols, has 406 relations at orbit representatives on 226 orbit averages, of rank 186; it is accepted at $\mathfrak{s} = 2$ with the spanning set 1, $e\,\alpha^{(-1,-1,-1,1,1,1)}$, $e\,\alpha^{(-1,-1,0,0,1,1)}$, $e\,\alpha^{(-2,-2,-2,2,2,2)}$, e the average over that group, and $Q_0 = (k-3)^5(k-2)^2(k+1)(k^3 - 8k^2 + \frac{71}{3}k - \frac{76}{3})$, $D_0 = 11$. The four orbits of native gauges give solutions of four distinct types, none vanishing at [1], so the spanning set is a set of masters of a submodule $\mathfrak{N}'$ of dimension 4 (Lemma 39.3), and $\mathbf{B}'(\infty)$ has the simple spectrum $400, 16, 4, -32$. Its rows of [1] are independent up to $h = 4$, so $\mathfrak{N}'$ is the cyclic submodule of [1]. Since $\pi_*[1] = [1]$ and $\pi_* \operatorname{Sh}' = \frac{k}{2(2k+1)} \operatorname{Sh} \pi_*$, $\pi_* \mathfrak{N}' = \mathfrak{N}_1$, and the law of [1] at the centre of $\binom{[6]}{3}$ is the law of $\binom{[5]}{2}$ for $\Gamma_{\substack{2\\1}}\begin{bmatrix} k,\ k \\ 2k \end{bmatrix} \langle 1 \rangle_k$: its coefficients are proportional to $p_i(k) \prod_{l=i}^{3} \frac{k+l}{2(2k+2l+1)}$, which is the law that the box gives, exactly (receipt `u36_lift.py`). So

$$\mathfrak{N} \cap \mathfrak{M}^{G'} = \mathfrak{N}_1 = \pi_* \mathfrak{N}', \qquad \mathfrak{N} \cap (1 - e_{G'}) \mathfrak{M}^G = L,$$

$\mathfrak{N}_1$ lying in $\mathfrak{M}^{G'}$, which contains [1], and L in $(1 - e_{G'})\mathfrak{M}^G$. At the centre of $\binom{[6]}{3}$ the closing equations have the dimensions $0, 1, 2, 3$ at $D = 10, \ldots, 13$, and no nonzero row of degree at most 40 is annihilated at $10 \le j \le 200$: the closings there single out $\mathbf{B}'$.

So: at the small centres of (i) the closings alone single out the box's matrix at the degree D_0, with nothing of low degree missed; at the centre of N_6 without its exchanges they miss the part that the exchanges negate; and at the centre of $\binom{[5]}{2}$, with every symmetry of the four kinds, the span of the box is the cyclic submodule of [1], which the box of $\binom{[6]}{3}$ reads, plus the line L that the symmetric group of $\binom{[6]}{3}$ hides from the closings, the values and $A_\star$, and that the signs see. $\square$

Chapter 55

Exercises on rays: other lists

These exercises read rays of lists other than the lists $\binom{\mathcal{E}}{1}$: the list H_4 on four marks at its centre and on a ray strictly inside its walls whose native value has a conjugate on the slit, and the five-mark lists along their hinge trees. Each exercise defines its list by its marks and its bases; every weight is 1. A recurrence of the closings is proved for every index by an explicit telescoping identity, and Theorems 39.33 and 39.57, with Corollary 39.60, carry it to the values. A *certificate* of a recurrence is an explicit element of the relation space $\mathcal{L}$ (Definition 38.4) that equals the recurrence applied to an insertion, as in Proposition 38.5(i); a telescoping identity among binomial sums is not one. Numbers are exact; a decimal is a rendering of an exact value, truncated. The receipts are the scripts `ex28_h4_centre.py`, `ex29_h4_lean.py` and `ex30_trees.py`, with the shared tools in `common.py`; each prints the numbers its solution displays.

55.1 The list H_4

In this section H_4 is the list on the marks $a, b, 2, 3$ whose bases are the five pairs other than $\{a, b\}$: $\{a, 2\}, \{a, 3\}, \{b, 2\}, \{b, 3\}, \{2, 3\}$. With $A = \alpha_a + \alpha_b$ and $B = \alpha_2 + \alpha_3$ its letters are

$$K = AB + \alpha_2\alpha_3, \qquad \Psi = AB + \alpha_a\alpha_b,$$

the second from the cobases $\{b, 3\}, \{b, 2\}, \{a, 3\}, \{a, 2\}, \{a, b\}$, and $\Psi(\alpha) = \alpha_a\alpha_b\alpha_2\alpha_3\, K(\alpha^{-1})$. The pair $\{a, b\}$ is a parallel class.

Exercise 55.1 (H_4 at its centre)**.** Let $P(k) = \langle 1\rangle_k = P_{\mathrm{H}_4}(k\mathbf{1}; k, k)$ be the values of the centre ray of H_4 at the strength one (Definition 38.13).

(i) Write the stride, the walls of the direction and V_1.

(ii) Find every native gauge of the ray with its native value, and decide which are nondegenerate.

(iii) Find the closings and a law of the values of order four, prove the law, and give its symbol.

(iv) Write $\Gamma(\sigma)^2 P(\sigma)$ on the share side of the hinge tree of H_4, close it at the integer strengths, and decide which of its two closings converges.

(v) Read the low-end relation, the principal parts of P at $k = 0$ and at $k = -1$, and the relation that the law gives at $k = -1$.

(vi) Give $P(1)$ and $P(2)$, and show that every value $P(k)$, $k \geq 1$, lies in $\mathbb{Q} + \mathbb{Q}\,P(1) + \mathbb{Q}\,P(2)$.

Solution. (i) Stride, walls, V_1. By Definition 38.13 the stride and its reciprocal are

$$f=\frac{\alpha_a\alpha_b\alpha_2\alpha_3}{K\Psi}=\frac{1}{K(\alpha)\,K(\alpha^{-1})},\qquad f^{-1}=\frac{(AB+\alpha_2\alpha_3)(AB+\alpha_a\alpha_b)}{\alpha_a\alpha_b\alpha_2\alpha_3},$$

and the walls of the direction are the widths, $\kappa_{1,S}=c(S)=r(S)+r(\mathcal{E}\setminus S)-2$ (Definition 7.12, Proposition 8.21(ii)). A single mark has rank one and its complement rank two; $\{a,b\}$ has rank one and $\{2,3\}$ rank two; the other pairs have rank two with complements of rank two; a triple has rank two and its complement rank one. So $\kappa_{1,S}=2$ for the four pairs $\{a,2\},\{a,3\},\{b,2\},\{b,3\}$, and $\kappa_{1,S}=1$ for every other nonempty proper S: all walls are positive. In $V_1=\sum_\pi\prod_{l=2}^{4}\kappa_{1,U_l}^{-1}$ (Proposition 39.34) the tails U_2 and U_4 have three marks and one mark, of wall 1, so an order contributes κ_{1,U_3}^{-1}, U_3 being its last two marks. Each of the six pairs ends four of the 24 orders, so

$$V_1=4\,(1+1)+4\cdot4\cdot\tfrac12=16.$$

(ii) Native gauges. By Proposition 38.16 a point α of X_F is a native gauge exactly when the occupations $R_e=\alpha_e\partial_{\alpha_e}\log K$ agree at α and at α^{-1}, and its native value is $\big(K(\alpha)K(\alpha^{-1})\big)^{-1}$. Here

$$R_a(\alpha)=\frac{\alpha_aB}{K},\quad R_a(\alpha^{-1})=\frac{\alpha_bB}{\Psi},\qquad R_2(\alpha)=\frac{\alpha_2(A+\alpha_3)}{K},\quad R_2(\alpha^{-1})=\frac{\alpha_3A+\alpha_a\alpha_b}{\Psi},$$

and R_b, R_3 follow by exchanging $a\leftrightarrow b$ and $2\leftrightarrow3$. So the native gauges are the solutions in X_F of

$$\begin{aligned}B(\alpha_a\Psi-\alpha_bK)&=0,&\qquad B(\alpha_b\Psi-\alpha_aK)&=0,\\ \alpha_2(A+\alpha_3)\Psi&=(\alpha_3A+\alpha_a\alpha_b)K,&\qquad \alpha_3(A+\alpha_2)\Psi&=(\alpha_2A+\alpha_a\alpha_b)K.\end{aligned}$$

The occupations add up to the rank 2 at α and at α^{-1}, so any three of the four equations imply the fourth.

If $B=0$, then $K=\alpha_2\alpha_3$ and $\Psi=\alpha_a\alpha_b$, and with $\alpha_3=-\alpha_2$ the third equation reads $\alpha_2A(\alpha_a\alpha_b-\alpha_2^2)=0$: either $A=0$ or $\alpha_a\alpha_b=\alpha_2^2$. If $B\neq0$, the first two equations give $(\alpha_a-\alpha_b)(\Psi+K)=0$ and $A(\Psi-K)=0$. For $A=0$ they leave $K=\alpha_2\alpha_3$, $\Psi=\alpha_a\alpha_b=-\alpha_a^2$ and $\Psi+K=0$, that is $\alpha_a^2=\alpha_2\alpha_3$, and the third equation, $\alpha_2\alpha_3\Psi=\alpha_a\alpha_bK$, holds there. For $A\neq0$ they give $\Psi=K$, that is $\alpha_a\alpha_b=\alpha_2\alpha_3$, and then $\alpha_a=\alpha_b$, since $\Psi+K=2K\neq0$; the third equation becomes $A(\alpha_2-\alpha_3)=0$, so $\alpha_2=\alpha_3$ and $\alpha_2^2=\alpha_a^2$. Up to scale the native gauges are therefore:

- the table's gauge $\mathbf{1}$, where $K=\Psi=5$: native value $\frac{1}{25}$;
- the sign $(1,1,-1,-1)$, where $K=\Psi=-3$: native value $\frac19$;
- the three curves $\{A=0,\ \alpha_a^2=\alpha_2\alpha_3\}$, $\{B=0,\ \alpha_2^2=\alpha_a\alpha_b\}$ and $\{A=B=0\}$, on which $K=\alpha_2\alpha_3$ and $\Psi=\alpha_a\alpha_b$: native value 1.

No letter vanishes at these points of the torus, so they lie in X_F. On the chart $y_3=0$, in the coordinates y_a,y_b,y_2, the Hessian of $-\log f$ at $\mathbf{1}$ is twice the covariance matrix of the indicators under the uniform weight law on the five bases (Theorem 38.15), and at the sign it is twice the covariance matrix under the signed measure $\mathbb{P}_\eta$ with the masses $\frac13,\frac13,\frac13,\frac13,-\frac13$ on $\{a,2\},\{a,3\},\{b,2\},\{b,3\},\{2,3\}$ (Theorem 38.17(ii)):

$$H_{\mathbf{1}}=\frac{2}{25}\begin{bmatrix}6&-4&-1\\-4&6&-1\\-1&-1&6\end{bmatrix},\quad \det H_{\mathbf{1}}=\frac{32}{625};\qquad H_\eta=\frac29\begin{bmatrix}2&-4&1\\-4&2&1\\1&1&2\end{bmatrix},\quad \det H_\eta=-\frac{32}{81}.$$

Both are nonsingular: the table's gauge and the sign are nondegenerate native gauges (Definition 38.4). The three curves are sources of dimension one (Definition 39.23), along which f is constant and the Hessian is singular.

(iii) Closings and the law. The origin is 0 and both letters have the exponent one, so the closings are $\mathsf{C}_j(1) = \mathrm{CT}(f^{-j})$ (Definition 39.30). In

$$(K\Psi)^j = \sum_{u,v} \binom{j}{u}\binom{j}{v} (AB)^{u+v} (\alpha_2\alpha_3)^{j-u} (\alpha_a\alpha_b)^{j-v}$$

the monomial $(\alpha_a\alpha_b\alpha_2\alpha_3)^j$ takes $\alpha_a^v\alpha_b^v$ from A^{u+v} and $\alpha_2^u\alpha_3^u$ from B^{u+v}, so $u = v$ and

$$\mathsf{C}_j(1) = \sum_{u=0}^{j} F(j,u), \qquad F(j,u) = \binom{j}{u}^2 \binom{2u}{u}^2; \qquad \mathsf{C}_j(1) = 1,\ 5,\ 53,\ 761,\ 12661,\ 229705,\ \ldots$$

Exact linear algebra on the first 150 closings gives one line of recurrences $\sum_{i=0}^{4} p_i(j)\,\mathsf{C}_{j+i}(1) = 0$ with $\deg p_i \le 7$, spanned by

$$\begin{aligned}
p_0(j) &= 225(j+1)^2(j+2)^2\,w(j), \qquad w(j) = 144j^3 + 1296j^2 + 3853j + 3790,\\
p_1(j) &= -2(j+2)^2(34848j^5 + 435600j^4 + 2135762j^3 + 5129622j^2 + 6027508j + 2768385),\\
p_2(j) &= 2(21168j^7 + 381024j^6 + 2917047j^5 + 12308044j^4\\
&\qquad + 30893608j^3 + 46094457j^2 + 37814839j + 13140768),\\
p_3(j) &= -2(j+3)(2592j^6 + 42768j^5 + 289602j^4 + 1028216j^3 + 2015044j^2 + 2063287j + 861336),\\
p_4(j) &= (j+3)(j+4)^3(144j^3 + 864j^2 + 1693j + 1089);
\end{aligned}$$

no recurrence of order at most three and degree at most 30 holds on the first 200 closings. The recurrence holds for every $j \in \mathbb{N}$, by a telescoping identity. For $0 \le u \le j+4$ put

$$T(j,u) = \frac{((j+4)!)^2\,((2u)!)^2}{(u!)^6\,((j+4-u)!)^2} > 0, \qquad G(j,u) = \frac{T(j,u)\,A(j,u)}{\prod_{l=1}^{4}(j+l)^2}, \qquad G(j,j+5) = 0,$$

with $A(j,u) = u^4(j+1)^2(j+2)^2 \sum_{q=0}^{4} Q_q(j)\,u^q$ and

$$\begin{aligned}
Q_0 &= (j+4)(6912j^6 + 125568j^5 + 938496j^4 + 3695236j^3 + 8085594j^2 + 9321748j + 4422321),\\
Q_1 &= -4(5760j^6 + 106272j^5 + 809680j^4 + 3260831j^3 + 7321143j^2 + 8687769j + 4256385),\\
Q_2 &= 2(13248j^5 + 198864j^4 + 1186148j^3 + 3514356j^2 + 5173077j + 3027087),\\
Q_3 &= -4(22j+63)\,w(j), \qquad Q_4 = 15\,w(j).
\end{aligned}$$

For $0 \le u \le j+4$, $F(j+i,u) = T(j,u)\prod_{l=i+1}^{4}\big((j+l-u)/(j+l)\big)^2$, which vanishes for $u > j+i$ as F does, and $T(j,u+1) = T(j,u)\,4(2u+1)^2(j+4-u)^2/(u+1)^4$, which vanishes at $u = j+4$. So, divided by $T(j,u)/\big((u+1)^4\prod_l (j+l)^2\big)$, the identity

$$\sum_{i=0}^{4} p_i(j)\,F(j+i,u) = G(j,u+1) - G(j,u) \qquad (0 \le u \le j+4)$$

is the identity of polynomials

$$(u+1)^4 \sum_{i=0}^{4} p_i(j) \prod_{l\le i}(j+l)^2 \prod_{l>i}(j+l-u)^2 = 4(2u+1)^2(j+4-u)^2 A(j,u+1) - (u+1)^4 A(j,u),$$

which holds in $\mathbb{Q}[j,u]$, both sides expanded. Summed over $0 \le u \le j+4$, the right side telescopes to $G(j,j+5) - G(j,0) = 0$, as $A(j,0) = 0$, and the left side is $\sum_i p_i(j)\,\mathsf{C}_{j+i}(1)$. So the closings satisfy the recurrence for every j.

The direction has the integral origin 0, both letter exponents 1 and positive walls. Written as $\sum_i c_i(-j)\,\mathsf{C}_{j-i}(1) = 0$ with $c_i(k) = -p_{4-i}(-k-4)$, the recurrence says that the closings vanish on $\sum_i c_i(k)\,\mathrm{Sh}^i[1]$ (Theorem 39.33); by Theorem 39.57 the values vanish on it as well, and the continuation of its value vanishes identically; Corollary 39.60 states the same for the recurrences of $\langle 1\rangle$. With $\langle f^i g\rangle_k = \langle g\rangle_{k+i}$ (Proposition 38.5(ii)) this is the law

$$\sum_{i=0}^{4} c_i(k)\,P(k+i) = 0,$$

an identity of meromorphic functions of k, with

$$\begin{aligned}
c_0(k) &= k^3(k+1)(144k^3+864k^2+1693k+1075),\\
c_1(k) &= -2(k+1)(2592k^6+19440k^5+56322k^4+80296k^3+60004k^2+23017k+3580),\\
c_2(k) &= 2(21168k^7+211680k^6+884919k^5+2003456k^4\\
&\qquad +2646984k^3+2031207k^2+830703k+137260),\\
c_3(k) &= -2(k+2)^2(34848k^5+261360k^4+741842k^3+984642k^2+598948k+127215),\\
c_4(k) &= 225(k+2)^2(k+3)^2(144k^3+432k^2+397k+102).
\end{aligned}$$

Its symbol (Corollary 38.7) is read off the coefficients of k^7:

$$\chi(\lambda) = 144 - 5184\lambda + 42336\lambda^2 - 69696\lambda^3 + 32400\lambda^4 = 144(25\lambda-1)(9\lambda-1)(\lambda-1)^2.$$

Its roots are the native values $\frac{1}{25}$ and $\frac{1}{9}$ of the two nondegenerate native gauges and the native value 1 of the curves, doubled; the root $\frac{1}{25} = f(\mathbf{1})$ is forced by Proposition 38.9.

(iv) The share side and its closings. A set of two marks has width one exactly for $\{a,b\}$ and $\{2,3\}$ (part (i)), so H_4 is the two-sum, at a hinge g, of the parallel cell $\mathcal{P}$ of $\{a,b\}$, with the core $\binom{\{g,a,b\}}{1}$, and the series cell $\mathcal{S}$ of $\{2,3\}$, with the core $\binom{\{g,2,3\}}{2}$: the bases $\{2,3\}$ and $\{x,y\}$, $x \in \{a,b\}$, $y \in \{2,3\}$, are those of the two-sum (Definition 23.15, Theorem 23.16). At the centre of real strength $\sigma > 0$, with the masses σ and $s = t = \sigma$, every mark is a one-mark cell of ratio 1, whose transform and dual transform are $\mathsf{g}(y) = \mathsf{G}_{0;(1,-1)}(1,y)$ (Definition 23.19(1)), and Theorem 23.14 gives

$$f_{\mathcal{S}} = \mathsf{g}^2, \quad \kappa_{\mathcal{S}} = 2\sigma - \sigma = \sigma; \qquad \check{f}_{\mathcal{P}} = \mathsf{g}^2, \quad \kappa_{\mathcal{P}} = 2\sigma - \sigma = \sigma.$$

The root of two one-mark leaves at the strength z (Definition 23.19(5)), whose transforms are again g, and the Beta integral give

$$\int_0^\infty y^{z-1}\mathsf{g}(y)^2\,dy = \Gamma(z)^2 P_2(z),$$

$$P_2(z) = P_{\binom{[2]}{1}}(z\mathbf{1}; z, z) = \int_0^\infty x^{z-1}(1+x)^{-2z}\,dx = \frac{\Gamma(z)^2}{\Gamma(2z)} \qquad (z>0).$$

By Proposition 23.8(iii), with $s = t = \kappa = \sigma$, the two Mellin transforms of the laws are $\int \varrho_{\mathcal{S}}^{-z} d\phi_{\mathcal{S}} = P_2(z)$ and $\int \varrho_{\mathcal{P}}^{z-\sigma} d\phi_{\mathcal{P}} = P_2(z)$ for $z > 0$. Theorem 23.9(iv) for one table, with $\mathcal{S}$ in the place of $\mathcal{A}$ and $\mathcal{P}$ in the place of $\mathcal{A}'$, on a line $\mathrm{Re}\, z = c$ with $0 < c < \sigma$, gives

$$\Gamma(\sigma)^2 P(\sigma) = \frac{1}{2\pi i}\int_{(c)} \Gamma(z)^2\,\Gamma(\sigma-z)^2\,P_2(z)^2\,dz = \frac{1}{2\pi i}\int_{(c)} \mathcal{F}(z,\sigma)\,dz, \qquad \mathcal{F} = \frac{\Gamma(z)^6\,\Gamma(\sigma-z)^2}{\Gamma(2z)^2},$$

and both sides are holomorphic in σ on $\operatorname{Re}\sigma > c$.

Closing (Theorem 4.5) moves the line across the poles of the Gammas on one side and needs the contribution of the moved line to tend to zero. At an integer strength $k \geq 1$, by the shift and the reflection of Proposition 1.3(iii),(v),

$$\Gamma(z)\,\Gamma(k-z) = \frac{\pi\,(z-1)(z-2)\cdots(z-k+1)}{\sin\pi(z-k+1)},$$
$$\mathcal{F}(z,k) = \frac{\pi^2\,V_k(z)\,P_2(z)^2}{\sin^2\pi(z-k+1)}, \qquad V_k(z) = \prod_{j=1}^{k-1}(z-j)^2.$$

On the line $\operatorname{Re} z = k+N+\frac12$, $|\sin\pi(z-k+1)| = \cosh(\pi \operatorname{Im} z)$, $|P_2(z)| \leq \int_0^1 \big(w(1-w)\big)^{\operatorname{Re} z-1} dw \leq 4^{1-\operatorname{Re} z}$ and $V_k(z)$ is a polynomial, so the contribution of that line is $O(N^{2k-2}16^{-N})$ and tends to zero. To the right the poles are the integers $x \geq k$, double, with the principal part $(z-x)^{-2}$ of $\pi^2/\sin^2$ and no simple part (Lemma 5.16), and closing to the right gives

$$\Gamma(k)^2 P(k) = -\sum_{x\geq k} \big(V_k P_2^2\big)'(x),$$
$$P(1) = \sum_{m\geq 0} \frac{4\,(m!)^4}{((2m+1)!)^2}\big(h_{2m+1} - h_m\big) = 4 + \frac{5}{54} + \frac{47}{13500} + \frac{319}{2058000} + \cdots,$$

with $h_n = \sum_{i=1}^n i^{-1}$, since $P_2'/P_2 = 2(\log\Gamma)'(x) - 2(\log\Gamma)'(2x)$ and $(\log\Gamma)'(n+1) - (\log\Gamma)'(1) = h_n$ (Proposition 1.3(vi)). The terms are rational and decrease like 16^{-x}: the share side of H_4 closes on the lattice of the integers to its right.

To the left the poles are at $z = -m$, $m \in \mathbb{N}$, of order four: $\Gamma(z)^6$ has order six there and $\Gamma(2z)^{-2}$ a double zero. With the duplication formula $\Gamma(2z) = \pi^{-1/2}2^{2z-1}\Gamma(z)\Gamma(z+\frac12)$ and the reflection,

$$\mathcal{F}(z,\sigma) = 4\pi^3\,16^{-z}\,\frac{\cos^2\pi z}{\sin^4\pi z}\,\mathcal{B}(z)^2, \qquad \mathcal{B}(z) = \frac{\Gamma(\frac12 - z)\,\Gamma(\sigma - z)}{\Gamma(1-z)^2},$$

so the residue at $-m$ is $16^m\,\mathcal{B}(-m)^2\big(c + O(m^{-1})\big)$ with $c = \frac{2}{3\pi}\log 16\,\big(2\pi^2 - (\log 16)^2\big) = 7.0911\ldots$: it is $4\pi^{-1}16^m/3!$ times the third derivative at 0 of $16^{-\varepsilon}\mathcal{B}(\varepsilon - m)^2(\pi\varepsilon)^4\cos^2(\pi\varepsilon)\sin^{-4}(\pi\varepsilon)$, in which the derivatives of $\log\mathcal{B}$ at $-m$ are $O(m^{-1})$; and $\mathcal{B}(-m)^2$ grows like $m^{2\sigma-3}$. At $\sigma = 1$ the ratios of consecutive residues are 14.5771, 15.2453, 15.4869, 15.6114 at $m = 10, 20, 30, 40$, against $16\big((m+\frac12)/(m+1)\big)^2 = 14.5785$, 15.2472, 15.4880, 15.6121, and the residue over $16^m\mathcal{B}(-m)^2$ is 7.1273, 7.1173, 7.1104, 7.1063. The residues grow like 16^m, and the closing to the left diverges.

(v) The low end. By (iii) the law holds as an identity of meromorphic functions. Near $k = 0$ the terms $i \geq 1$ are holomorphic, c_0 vanishes to order three, $[k^3]c_0 = 1075$, and $\lim_{k\to 0} k^3 P(k) = V_1\,\mathsf{C}_0(1) = 16$ (Proposition 39.34); the value of the law at 0 is the low-end relation, by the argument of Corollary 39.38(ii), which uses of the law only that it holds as an identity of meromorphic functions:

$$17200 - 7160\,P(1) + 274520\,P(2) - 1017720\,P(3) + 826200\,P(4) = 0.$$

At $k = -1$ the coefficients c_0 and c_1 vanish, simply, while $c_2(-1) = -342$, $c_3(-1) = 4842$, $c_4(-1) = -6300$, so the value of the law at -1 is

$$\operatorname*{CT}_{k=-1}\big(c_0(k)P(k) + c_1(k)P(k+1)\big) - 342\,P(1) + 4842\,P(2) - 6300\,P(3) = 0,$$

and the first term needs the principal parts of P at -1 and at 0. The share side gives them. On the line $\operatorname{Re} z = \frac12$ the bound $|\Gamma(c'+i\tau)| \leq C_{c'}e^{-\pi|\tau|/2}(1+|\tau|)^{c'-1/2}$, with $1/\Gamma(2z) = \Gamma(1-2z)\sin(2\pi z)/\pi$,

makes $|\mathcal{F}(z,\sigma)|$ at most a constant times $(1+|\operatorname{Im} z|)^{2\operatorname{Re}\sigma} e^{-2\pi|\operatorname{Im} z|}$ for $|\operatorname{Im} z| \geq 1$, uniformly for σ in compact sets; so $J(\sigma) = \frac{1}{2\pi i}\int_{(1/2)} \mathcal{F}\,dz$ is holomorphic wherever no pole of $\Gamma(\sigma - z)^2$ lies on the line, in particular on the strips $|\operatorname{Re}\sigma| < \frac{1}{2}$ and $-\frac{3}{2} < \operatorname{Re}\sigma < -\frac{1}{2}$. For $\operatorname{Re}\sigma > \frac{1}{2}$, $\Gamma(\sigma)^2 P(\sigma) = J(\sigma)$. As σ moves left the double poles $z = \sigma$ and then $z = \sigma + 1$ of $\Gamma(\sigma - z)^2$ cross the line, and the identity of meromorphic functions that continues it is

$$\Gamma(\sigma)^2 P(\sigma) = J(\sigma) - R_0(\sigma) \qquad (|\operatorname{Re}\sigma| < \tfrac{1}{2}),$$
$$\Gamma(\sigma)^2 P(\sigma) = J(\sigma) - R_0(\sigma) - R_1(\sigma) \qquad (-\tfrac{3}{2} < \operatorname{Re}\sigma < -\tfrac{1}{2}),$$

with the residues, by Proposition 5.14 at $p = 2$,

$$R_m(\sigma) = \operatorname*{Res}_{z=\sigma+m} \mathcal{F} = \frac{\Gamma(\sigma+m)^6}{(m!)^2\,\Gamma(2\sigma+2m)^2}\Big(6(\log\Gamma)'(\sigma+m) - 4(\log\Gamma)'(2\sigma+2m) - 2(\log\Gamma)'(m+1)\Big).$$

$\Gamma(\sigma)^{-2}$ vanishes to order two at 0 and at -1, so J enters P there only from the order $(\sigma - \sigma_0)^2$ on, and the principal parts of P are those of $-R_0\,\Gamma^{-2}$ and of $-(R_0 + R_1)\,\Gamma^{-2}$. Expanding every Gamma factor at its pole or regular point by Proposition 5.14, in $(\log\Gamma)'(1)$ and the Trailmoments $(\mathsf{T}_{n;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ of the counting input, gives $R_0(x) = -16x^{-5} - 32(\log\Gamma)'(1)\,x^{-4} + O(x^{-3})$ near 0 and $(R_0 + R_1)(-1+x) = -80x^{-5} + O(x^{-4})$ near -1, and, the terms in $(\log\Gamma)'(1)$ cancelling,

$$P(x) = \frac{16}{x^3} - \frac{24\,(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))}{x} + O(1),$$
$$P(-1+x) = \frac{80}{x^3} - \frac{152}{x^2} - \frac{120\,(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))}{x} + O(1),$$

with $(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = \sum_{n\geq 1} n^{-2} = \frac{1}{6}\Gamma(\frac{1}{2})^4$ (Lemma 5.16 at $a = \frac{1}{2}$). The top coefficients are $V_1\,\mathsf{C}_0(1) = 16$ and $V_1\,\mathsf{C}_1(1) = 80$ (Proposition 39.34), and the coefficient 0 of x^{-2} at 0 is the low-end coefficient L_1, which vanishes for a list (Proposition 39.39, every weight being 1). With

$$c_0(-1+x) = -102x - 91x^2 + 453x^3 + O(x^4), \qquad c_1(-1+x) = 510x - 514x^2 - 3056x^3 + O(x^4),$$

and $T = (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$, the coefficients of x^{-2} and x^{-1} in $c_0(k)P(k) + c_1(k)P(k+1)$ at $k = -1 + x$ are $-102\cdot 80 + 510\cdot 16 = 0$ and $-102\cdot(-152) - 91\cdot 80 - 514\cdot 16 = 0$, as the law asks, and its constant term is

$$-102\cdot(-120T) - 91\cdot(-152) + 453\cdot 80 + 510\cdot(-24T) - 514\cdot 0 - 3056\cdot 16 = 1176:$$

the multiples of $\Gamma(\frac{1}{2})^4$ cancel. Hence $-342\,P(1) + 4842\,P(2) - 6300\,P(3) = -1176$, that is

$$57\,P(1) - 807\,P(2) + 1050\,P(3) = 196,$$

the second low-end relation.

(vi) Values and their span. The share side at $\sigma = 1,\dots,5$, integrated on the line $\operatorname{Re} z = \frac{1}{2}$ in ball arithmetic, and the closing of (iv), summed over its first 80 terms at $k = 1, 2, 3$, agree to 80 digits and give

$$P(1) = 4.0962369983378828500555532283512\ldots,$$
$$P(2) = 0.047716498691513110297412080890663\ldots;$$

the law at $k = 1$, the low-end relation and the second low-end relation hold at these values to 75 digits. For $k \geq 1$, $c_4(k) > 0$, so the law gives $P(k+4)$ as a rational combination of

$P(k),\dots,P(k+3)$; the second low-end relation gives $P(3)$, and then the low-end relation $P(4)$, in $\mathbb{Q}+\mathbb{Q}\,P(1)+\mathbb{Q}\,P(2)$. So every value lies in $\mathbb{Q}+\mathbb{Q}\,P(1)+\mathbb{Q}\,P(2)$. An integer-relation search at 290 bits finds no relation among 1, $P(1)$, $P(2)$ with coefficients below 10^{25}.

Answer. $V_1=16$. The native gauges are $\mathbf{1}$ (native value $\frac{1}{25}$, $\det H=\frac{32}{625}$), the sign $(1,1,-1,-1)$ ($\frac{1}{9}$, $\det H=-\frac{32}{81}$) and three curves of native value 1. The closings are $\sum_u \binom{j}{u}^2\binom{2u}{u}^2$; the law is the display of (iii), of symbol $144(25\lambda-1)(9\lambda-1)(\lambda-1)^2$, proved by the telescoping identity and Theorem 39.57. On the share side $\Gamma(\sigma)^2P(\sigma)=\frac{1}{2\pi i}\int\Gamma(z)^6\Gamma(\sigma-z)^2\Gamma(2z)^{-2}dz$; it closes to the right, $\Gamma(k)^2P(k)=-\sum_{x\ge k}(V_kP_2^2)'(x)$, and not to the left. The low-end relation is $17200-7160P(1)+274520P(2)-1017720P(3)+826200P(4)=0$, the second low-end relation $57P(1)-807P(2)+1050P(3)=196$, and the values lie in $\mathbb{Q}+\mathbb{Q}\,P(1)+\mathbb{Q}\,P(2)$. □

Exercise 55.2 (H_4 on a ray with a conjugate on the slit)**.** On H_4 take the masses $\mathbf{m}_1=(1,1,3,3)$ on $(a,b,2,3)$ and the letter exponents $s_1=3$, $t_1=1$, and let $P(k)=\langle1\rangle_k=P_{\mathrm{H}_4}\big(k\mathbf{m}_1;3k,k\big)$, $k\ge1$, be the values of the ray with the origin 0 and the direction $(\mathbf{m}_1;3,1)$.

(i) Show that the direction lies on the balance wall and strictly inside its walls, and compute V_1.

(ii) Find the native gauge $\alpha^\star$ of the direction on the positive orthant, $f^\star=f(\alpha^\star)$ and its conjugate over $\mathbb{Q}$, and show that the conjugate is the native value of a nondegenerate native gauge and lies on the slit $(0,f^\star)$.

(iii) Find the closings and a law of the values of order four, prove the law, and give its symbol.

(iv) Write the low-end relation, and show that Theorem 41.3(iii) does not apply.

(v) Read $P(1)$ and $P(2)$ from the gauge end (Theorem 40.6), and check them against the low-end relation.

(vi) Write $\Gamma(3k)\Gamma(k)P(k)$ on the share side, read the second low-end relation from it, and give the value span.

Solution. (i) Walls and V_1. The direction has $m_{1,\mathcal{E}}=8=3r+1\cdot r^*=3\cdot2+2$, on the balance wall. Its walls are $\kappa_{1,S}=m_{1,S}-3d(S)-d^*(S)$ (Definition 8.1), with $d(S)=|S|-r^*(S)$ and $d^*(S)=|S|-r(S)$ (Definition 7.12). A single mark has $d=d^*=0$; $\{a,b\}$ has $d=0$, $d^*=1$; $\{2,3\}$ has $d=1$, $d^*=0$; the four pairs $\{x,y\}$, $x\in\{a,b\}$, $y\in\{2,3\}$, have $d=d^*=0$; every triple has $d=d^*=1$. So

$$\kappa_{1,S}=1\quad\text{for } S\in\big\{\{a\},\{b\},\{a,b\},\{a,b,2\},\{a,b,3\}\big\},$$
$$\kappa_{1,S}=3\quad\text{for } S\in\big\{\{2\},\{3\},\{2,3\},\{a,2,3\},\{b,2,3\}\big\},$$

and $\kappa_{1,S}=4$ for the four pairs $\{x,y\}$: all positive. An order of the marks is the chain of its tails $U_2\supset U_3\supset U_4$, and $V_1=\sum\big(\kappa_{1,U_2}\kappa_{1,U_3}\kappa_{1,U_4}\big)^{-1}$ (Proposition 39.34). Below $U_2=\{a,b,y\}$ the pairs and their marks give $1\cdot(1+1)+2\cdot\frac14(1+\frac13)=\frac83$; below $U_2=\{x,2,3\}$ they give $2\cdot\frac14(1+\frac13)+\frac13(\frac13+\frac13)=\frac89$. So

$$V_1=2\cdot\frac83+2\cdot\frac13\cdot\frac89=\frac{160}{27}.$$

(ii) The native gauge and its conjugate. The exchanges $a\leftrightarrow b$ and $2\leftrightarrow3$ keep the direction, and $\alpha^\star$ is unique up to scale (Theorem 38.14(i)), so $\alpha^\star=(x,x,1,1)$ for some $x>0$. On that slice $K=4x+1$, $\Psi=x(x+4)$ and

$$f=\frac{\alpha_a\alpha_b\alpha_2^3\alpha_3^3}{K^3\Psi}=\frac{x}{(x+4)(4x+1)^3},\qquad\frac{d}{dx}\log f=\frac{-4(3x^2+8x-1)}{x(x+4)(4x+1)},$$

so $x^\star = \frac{\sqrt{19}-4}{3}$, where the gradient of $\log f$ vanishes in all four coordinates, and

$$f^\star = \frac{7643+1064\sqrt{19}}{1366875} = 0.0089846317\ldots, \qquad \det H = \frac{376096\sqrt{19}-1614848}{151875} = 0.16142523\ldots,$$

H the Hessian of $-\log f$ on the chart $y_3 = 0$; $f^\star$ is a root of $1366875\lambda^2 - 15286\lambda + 27$. By Proposition 38.10 the conjugate point $\alpha' = (x', x', 1, 1)$, $x' = \frac{-\sqrt{19}-4}{3} = -2.786\ldots$, where $K = \frac{-13-4\sqrt{19}}{3}$ and $\Psi = x'(x'+4)$ do not vanish, is a nondegenerate native gauge, with

$$f(\alpha') = \frac{7643-1064\sqrt{19}}{1366875} = 0.0021985415\ldots,$$
$$\det H(\alpha') = \frac{-376096\sqrt{19}-1614848}{151875} = -21.4269\ldots,$$

and $0 < f(\alpha') < f^\star$: the conjugate lies on the slit, at a gauge where the class $\{a, b\}$ is flipped.

(iii) Closings and the law. Every letter exponent of the direction is positive and the origin is 0, so $\mathsf{C}_j(1) = \mathrm{CT}(f^{-j}) = [\alpha^{j\mathbf{m}_1}] K^{3j}\Psi^j$ (Definition 39.30). In

$$K^{3j}\Psi^j = \sum_{u,v} \binom{3j}{u}\binom{j}{v} (AB)^{4j-u-v} (\alpha_2\alpha_3)^u (\alpha_a\alpha_b)^v$$

the monomial $\alpha_a^j\alpha_b^j\alpha_2^{3j}\alpha_3^{3j}$ takes $(\alpha_a\alpha_b)^{j-v}$ from A^{4j-u-v} and $(\alpha_2\alpha_3)^{3j-u}$ from B^{4j-u-v}, so $u = 2j+v$, with the coefficient $\binom{2j-2v}{j-v}^2$; with $w = j-v$,

$$\mathsf{C}_j(1) = \sum_{w=0}^{j} F(j,w), \qquad F(j,w) = \binom{3j}{w}\binom{j}{w}\binom{2w}{w}^2;$$
$$\mathsf{C}_j(1) = 1,\ 13,\ 589,\ 37597,\ 2791949,\ \ldots$$

On the first 300 closings there is no recurrence of order one, two, three with degree at most 138, 91, 68, and none of order four with degree at most 24; at order four and degree 25 exact linear algebra on the first 170 closings gives one line, spanned by $p_0, \ldots, p_4 \in \mathbb{Z}[j]$ with coefficients of up to 36 digits, and the recurrence holds on all 300. It holds for every j. For $0 \le w \le j+4$ put

$$T(j,w) = \frac{((2w)!)^2}{(w!)^6\,(3j+12-w)!\,(j+4-w)!},$$
$$G(j,w) = (3j)!\,j!\,T(j,w)\,A(j,w), \qquad G(j,j+5) = 0,$$

with $A \in \mathbb{Q}[j,w]$, a polynomial of 416 terms, of degree 16 in w and divisible by w^4, printed by the receipt. As $F(j+i,w) = (3j)!\,j!\,T(j,w)\prod_{l=1}^{3i}(3j+l)\prod_{l=1}^{i}(j+l)\prod_{l=3i+1}^{12}(3j+l-w)\prod_{l=i+1}^{4}(j+l-w)$ and $T(j,w+1) = T(j,w)\,4(2w+1)^2(3j+12-w)(j+4-w)/(w+1)^4$, the identity $\sum_i p_i(j)F(j+i,w) = G(j,w+1) - G(j,w)$ for $0 \le w \le j+4$ is the identity of polynomials

$$(w+1)^4 N(j,w) = 4(2w+1)^2(3j+12-w)(j+4-w)A(j,w+1) - (w+1)^4 A(j,w),$$

$N = \sum_i p_i(j)\prod_{l=1}^{3i}(3j+l)\prod_{l=1}^{i}(j+l)\prod_{l=3i+1}^{12}(3j+l-w)\prod_{l=i+1}^{4}(j+l-w)$, which holds in $\mathbb{Q}[j,w]$; summed over w it telescopes to 0, as $A(j,0) = 0$. As in Exercise 55.1(iii), Theorems 39.33 and 39.57 turn it into the law

$$\sum_{i=0}^{4} c_i(k)\,P(k+i) = 0, \qquad c_i(k) = -p_{4-i}(-k-4),$$

an identity of meromorphic functions of k. The coefficients factor as

$$c_0 = 3k^3(k+1)(3k+1)^3(3k+2)^3a_0, \qquad c_1 = -2(k+1)a_1, \qquad c_2 = 2(3k+4)(3k+5)a_2,$$
$$c_3 = -2(3k+4)(3k+5)(3k+7)(3k+8)(k+2)^2a_3,$$
$$c_4 = 151875(3k+4)(3k+5)(3k+7)(3k+8)(3k+10)(3k+11)(k+2)^2(k+3)^2a_4,$$

with $a_i \in \mathbb{Z}[k]$ of degrees $15, 24, 23, 19, 15$, printed by the receipt, and the symbol is

$$\chi(\lambda) = 168132676253771376\,(\lambda-1)^2\,(1366875\lambda^2 - 15286\lambda + 27)\,:$$

$f^\star$, its conjugate, and 1, doubled. The root 1 is the native value of the line $\{A = B = 0\}$, a source of dimension one (Definition 39.23): there $K = \alpha_2\alpha_3$ and $\Psi = \alpha_a\alpha_b$, the occupations of K and of Ψ are $(0,0,1,1)$ and $(1,1,0,0)$ on $(a,b,2,3)$, so the usage $3R + R^*$ is $\mathbf{m}_1$, and $f = 1$.

(iv) The low end and positive selection. c_0 vanishes to order three at 0 with $[k^3]c_0 = 656679698393897858976$, and with $V_1 = \frac{160}{27}$ the argument of Corollary 39.38(ii) gives the low-end relation, divided by 15360,

$$253348649071719853 + 204923553451974000\,P(1) - 272918959559705480400\,P(2)$$
$$+ 1177478827066019041200\,P(3) - 1011712684533185250000\,P(4) = 0.$$

Theorem 41.3 asks the roots of the symbol to be distinct, which the double root 1 already violates, and (iii) asks every root other than $f^\star$ to have modulus greater than $f^\star$. The conjugate $f(\alpha')$ lies in $(0, f^\star)$, so a solution of the law that grows like $f(\alpha')^k$ grows more slowly than the values, and growth does not separate it from them: the hypothesis fails. Set up anyway, the equations of Theorem 41.3(iv), with $P(1), P(2), P(3)$ free, $P(4)$ from the low-end relation and the solution required to vanish at $K, K+1, K+2$, return $P(1) = -2.6 \cdot 10^{23}$ at $K = 40$ and $-7.4 \cdot 10^{47}$ at $K = 80$.

(v) The gauge end. $f^\star$ is a simple root of χ, and the density operator $\mathfrak{D}_{\mathbf{p}}$ of the law (Theorem 40.6) has order $D = 25$; at $f^\star$ its coefficient $b_{D,0}$ vanishes and the extra exponent is $\gamma = D - 1 - b_{D-1,0}/b_{D,1} = \frac{1}{2} = \frac{n-3}{2}$, as Theorem 40.6(iii) requires. As $\gamma \notin \{0, \dots, 23\}$, the germ of the density is $\varrho_f(t) = s^{1/2}g(0)\Phi(s)$, $s = f^\star - t$, with Φ fixed by the recursion of Theorem 40.6(iv), 1800 terms computed over $\mathbb{Q}(\sqrt{19})$ in ball arithmetic, and the scale read off the Hessian at $\alpha^\star$ (the end of the stride's law at $f^\star$, Definition 40.1, with $(\omega_0/dy)(\alpha^\star) = 1$):

$$g(0) = \frac{1}{\Gamma(\frac{3}{2})\sqrt{\det H}}\Big(\frac{2\pi}{f^\star}\Big)^{3/2} = 51938.4198592508155915\dots$$

By Theorem 40.6(v) the density continues holomorphically along $(0, f^\star)$, through the root $f(\alpha')$ of the symbol, so the series of Φ converges on $[0, f^\star)$: the coefficients g_m of $g = g(0)\Phi$ have $|g_m|(f^\star)^m \le 5.2 \cdot 10^5$ for $m \le 1800$. The Beta integral gives

$$P(k) = \int_0^{f^\star} t^k \varrho_f(t)\,dt = \sum_{m \ge 0} g_m\,(f^\star)^{k+\frac{3}{2}+m}\,\mathrm{B}\big(k+1, m+\tfrac{3}{2}\big),$$

read at $k = K, \dots, K+3$, and the law, with $c_0(k) \neq 0$ at every integer $1 \le k \le 200$, runs back to $k = 1$. From $K = 80$ and from $K = 120$ the readings agree to 92 digits:

$$P(1) = 0.48830319489526888388541464396010900874354031922042\dots,$$

$$P(2) = 0.00132119179498773222717641714721510065075969610885\ldots$$

The low-end relation, which the reading does not use, returns $V_1 = \frac{160}{27}$ from these values to 191 digits.

(vi) The share side and the second low-end relation. The widths of (i) of Exercise 55.1 do not depend on the direction, so the hinge tree is the same: the series cell $\mathcal{S}$ of $\{2,3\}$, whose two marks have the masses $3k$, and the parallel cell $\mathcal{P}$ of $\{a,b\}$, with the masses k, at $s = 3k$, $t = k$. Every mark is again a one-mark cell whose transform, or dual transform, is g (Definition 23.19(1): $s = m_2 = m_3$, $t = m_a = m_b$), the hinge walls are $\kappa_{\mathcal{S}} = 6k - 3k = 3k$ and $\kappa_{\mathcal{P}} = 2k - k = k$, the walls of $\{2,3\}$ and $\{a,b\}$ (Theorem 23.14), and Proposition 23.8(iii) gives $\int \varrho_{\mathcal{S}}^{-z} d\phi_{\mathcal{S}} = P_2(z) = \int \varrho_{\mathcal{P}}^{z-k} d\phi_{\mathcal{P}}$. Theorem 23.9(iv), on a line $\operatorname{Re} z = c$, $0 < c < k$, gives

$$\Gamma(3k)\Gamma(k)\,P(k) = \frac{1}{2\pi i}\int_{(c)} \frac{\Gamma(z)^6\,\Gamma(k-z)\,\Gamma(3k-z)}{\Gamma(2z)^2}\,dz,$$

which at $k = 1$, on $c = \frac{1}{2}$ in ball arithmetic, agrees with (v) to 60 digits. At $k = -1$ the coefficients c_0 and c_1 vanish, simply, and the second low-end relation needs the principal parts of P at 0 and -1. As in Exercise 55.1(v), the integral on $\operatorname{Re} z = \frac{1}{2}$ is holomorphic near $k = 0$ and $k = -1$, $\Gamma(3k)\Gamma(k)$ has a double pole at both, and the principal parts of P come from the poles that cross the line, $z = k$ and $z = 3k$ near 0, and $z = k, k+1$ and $z = 3k, \ldots, 3k+3$ near -1, each simple, with the residues $(-1)^{m+1}\Gamma(2k-m)\,\Gamma(k+m)^6/\big(m!\,\Gamma(2k+2m)^2\big)$ at $z = k+m$ and $(-1)^{m+1}\Gamma(-2k-m)\,\Gamma(3k+m)^6/\big(m!\,\Gamma(6k+2m)^2\big)$ at $z = 3k+m$ (Proposition 1.3(iv)). Expanded by Proposition 5.14, with $T = (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$,

$$P(x) = \frac{160}{27x^3} - \frac{208\,T}{9x} + O(1), \qquad P(-1+x) = \frac{2080}{27x^3} - \frac{21118}{81x^2} - \frac{2704\,T + \frac{887}{9}}{9x} + O(1),$$

with the top coefficients $V_1\mathsf{C}_0(1)$ and $V_1\mathsf{C}_1(1) = \frac{160}{27}\cdot 13$ (Proposition 39.34). With the expansions of c_0 and c_1 at -1 to the order three, the multiples of T cancel in the constant term at $k = -1$, which is -2077616120857361856, and $(c_2, c_3, c_4)(-1) = 625190400\cdot(7005765879, -74409017489, 88989468750)$; so

$$7005765879\,P(1) - 74409017489\,P(2) + 88989468750\,P(3) = \frac{5981712159277}{1800},$$

which the values of (v) satisfy to 109 digits. For $k \geq 1$, $c_4(k) > 0$ (its real roots are below $\frac{1}{9}$), so, as in Exercise 55.1(vi), every value lies in $\mathbb{Q} + \mathbb{Q}\,P(1) + \mathbb{Q}\,P(2)$.

Answer. $V_1 = \frac{160}{27}$; $f^\star = \frac{7643+1064\sqrt{19}}{1366875}$ at $\alpha^\star = (x^\star, x^\star, 1, 1)$, $x^\star = \frac{\sqrt{19}-4}{3}$, $\det H = \frac{376096\sqrt{19}-1614848}{151875}$; its conjugate $\frac{7643-1064\sqrt{19}}{1366875}$ is the native value of the nondegenerate native gauge $(x', x', 1, 1)$, $x' = \frac{-\sqrt{19}-4}{3}$, and lies on the slit. The closings are $\sum_w \binom{3j}{w}\binom{j}{w}\binom{2w}{w}^2$, the law has order four, degree 25 and the symbol $(\lambda-1)^2(1366875\lambda^2 - 15286\lambda + 27)$ up to a constant, positive selection does not apply, and the gauge end gives $P(1) = 0.4883031948952688838854\ldots$ The second low-end relation is $7005765879P(1) - 74409017489P(2) + 88989468750P(3) = \frac{5981712159277}{1800}$, and the value span is $\mathbb{Q} + \mathbb{Q}\,P(1) + \mathbb{Q}\,P(2)$. □

55.2 The five-mark lists

In this section the marks are $1, \ldots, 5$, every weight is 1, and $\ell = P_{\binom{[3]}{1}}(\mathbf{1}; 1, 1)$ is the value at the strength one of the centre ray of the list $\binom{[3]}{1}$, $P_3(\sigma) = P_{\binom{[3]}{1}}(\sigma\mathbf{1}; \sigma, \sigma)$ $P_2(\sigma) = P_{\binom{[2]}{1}}(\sigma\mathbf{1}; \sigma, \sigma) =$

$\Gamma(\sigma)^2/\Gamma(2\sigma)$, and $\mathsf{g}(y) = \mathsf{G}_{0;(1,-1)}(1,y)$ as in Exercise 55.1(iv). The lists are $\binom{[5]}{1}$ and $\binom{[5]}{2}$, and three lists of rank two named by their parallel classes:

- P_5, whose bases are the nine pairs other than $\{1,2\}$: the classes $\{1,2\},\{3\},\{4\},\{5\}$;
- R_5, whose bases are the eight pairs $\{x,y\}$ with x,y in different classes of $\{1,2\},\{3,4\},\{5\}$;
- T_5, whose bases are the seven pairs $\{x,y\}$ with x,y in different classes of $\{1,2,3\},\{4\},\{5\}$.

Exercise 55.3 (The five-mark lists along their hinge trees)**.** (i) Find, for each of the five lists, the sets of width one with at least two marks on each side, and its canonical hinge tree.

(ii) Show that $P_{\mathrm{P}_5}(\sigma\mathbf{1};\sigma,\sigma) = P_3(\sigma)^2$. Prove the law of P_3, and derive from it the law of the centre ray of P_5, its symbol, its low-end relation and its value span.

(iii) Show that $q(\sigma) = P_{\binom{[4]}{2}}(\sigma\mathbf{1};\sigma,\sigma) = P_2(\sigma)P_3(\sigma)$, and find the law of q.

(iv) Write the centres of T_5 and R_5 on their share sides, close T_5 at the integer strengths, and write $P_{\mathrm{T}_5}(\mathbf{1};1,1)$ in the coordinates 1, ℓ and $\ell' = \partial_\sigma P_3(\sigma)|_{\sigma=1}$.

Solution. (i) Widths and trees. The width of S is $c(S) = r(S) + r(\mathcal{E}\setminus S) - r$ (Definition 7.12). In $\binom{[5]}{1}$ every nonempty set has rank one, so every proper S has width 1, and the list is one parallel node. In $\binom{[5]}{2}$ every set of two or three marks has rank two and so has its complement: width 2, and the list is prime (Theorem 23.16); so is $\binom{[4]}{2}$, whose pairs have width 2. In a list of rank two whose classes are the parallel classes, a set of two or three marks has width one exactly when it, or its complement, lies in one class, and width two otherwise. So the sets of width one with at least two marks on each side are $\{1,2\}$ for P_5; $\{1,2\}$ and $\{3,4\}$ for R_5; $\{1,2,3\}$ and its pairs for T_5; each with its complement. The canonical hinge trees (Definition 23.15, Theorem 23.16) are:

- $\binom{[5]}{1}$: one parallel node; $\binom{[5]}{2}$: one prime node;
- P_5: the parallel node $\binom{\{g,1,2\}}{1}$ and the prime node $\binom{\{g,3,4,5\}}{2}$;
- R_5: the series node $\binom{\{g_1,g_2,5\}}{2}$ with the parallel nodes $\binom{\{g_1,1,2\}}{1}$ and $\binom{\{g_2,3,4\}}{1}$;
- T_5: the series node $\binom{\{g,4,5\}}{2}$ with the parallel node $\binom{\{g,1,2,3\}}{1}$ of four marks.

For P_5, for instance, the bases of the two-sum are $\{x,y\}\subseteq\{3,4,5\}$, from $\{g\}$ and a pair of $\{3,4,5\}$, and $\{1,y\}$, $\{2,y\}$, $y\in\{3,4,5\}$, from $\{1\}$ or $\{2\}$ and $\{g,y\}$: the nine pairs other than $\{1,2\}$.

(ii) The doubled mark of $\binom{[4]}{2}$. The cell $\mathcal{A} = \binom{\{g,3,4,5\}}{2}$ of the bunch $\{3,4,5\}$ has the hinge minors $\mathcal{A}\setminus g = \binom{\{3,4,5\}}{2}$ and $\mathcal{A}/g = \binom{\{3,4,5\}}{1}$, dual with the identity and the same weights, so by Corollary 23.12(ii) its ratio is identically 1 and $\phi_{\mathcal{A}}(\Delta) = P_{\binom{[3]}{2}}(\sigma\mathbf{1};\kappa_{\mathcal{A}},2\sigma-\kappa_{\mathcal{A}})$, with the hinge wall $\kappa_{\mathcal{A}} = \sigma\, c(\{3,4,5\}) = \sigma(2+1-2) = \sigma$. By Corollary 23.12(i) the cell acts in the gluing as $\phi_{\mathcal{A}}(\Delta)$ times one mark e of ratio 1 and mass σ, and the parallel cell of $\{1,2\}$ glued to that mark is the list $\binom{\{1,2,e\}}{1}$. By Proposition 8.15 the dual table $\binom{[3]}{1}$ at the swapped exponents (σ,σ) has the same period, so

$$P_{\mathrm{P}_5}(\sigma\mathbf{1};\sigma,\sigma) = P_{\binom{[3]}{2}}(\sigma\mathbf{1};\sigma,\sigma)\,P_{\binom{\{1,2,e\}}{1}}(\sigma\mathbf{1};\sigma,\sigma) = P_3(\sigma)^2.$$

The law of P_3. The centre ray of $\binom{[3]}{1}$ has $f^{-1} = (\alpha_1+\alpha_2+\alpha_3)(\alpha_1^{-1}+\alpha_2^{-1}+\alpha_3^{-1})$, and its closings are (Definition 39.30)

$$\mathsf{C}_j(1) = \sum_{a+b+c=j}\Big(\frac{j!}{a!\,b!\,c!}\Big)^2 = \sum_{u=0}^{j}\binom{j}{u}^2\binom{2u}{u} = 1,\ 3,\ 15,\ 93,\ 639,\ 4653,\ \ldots,$$

grouping $a+b=u$. No recurrence of order one and degree at most 40 holds on the first 120 closings, and exact linear algebra gives

$$(j+2)^2\,\mathsf{C}_{j+2}(1)-(10j^2+30j+23)\,\mathsf{C}_{j+1}(1)+9(j+1)^2\,\mathsf{C}_j(1)=0.$$

It holds for every j: with $F(j,u)=\binom{j}{u}^2\binom{2u}{u}$, $T(j,u)=((j+2)!)^2(2u)!/\big((u!)^4((j+2-u)!)^2\big)$ for $0\le u\le j+2$, $A(j,u)=u^3(j+1)^2(3u-4j-8)$ and $G(j,u)=T(j,u)A(j,u)/((j+1)^2(j+2)^2)$, $G(j,j+3)=0$, one has $F(j+i,u)=T(j,u)\prod_{l=i+1}^{2}\big((j+l-u)/(j+l)\big)^2$ and $T(j,u+1)=T(j,u)\,2(2u+1)(j+2-u)^2/(u+1)^3$, so the identity $\sum_i p_i(j)F(j+i,u)=G(j,u+1)-G(j,u)$, $p_0=9(j+1)^2$, $p_1=-(10j^2+30j+23)$, $p_2=(j+2)^2$, is the identity of polynomials

$$(u+1)^3\sum_{i=0}^{2}p_i(j)\prod_{l\le i}(j+l)^2\prod_{l>i}(j+l-u)^2=2(2u+1)(j+2-u)^2A(j,u+1)-(u+1)^3A(j,u),$$

which holds in $\mathbb{Q}[j,u]$; summed over u it telescopes to 0. As in Exercise 55.1(iii), Theorems 39.33 and 39.57 give the law of the values, an identity of meromorphic functions,

$$k^2P_3(k)-(10k^2+10k+3)\,P_3(k+1)+9(k+1)^2\,P_3(k+2)=0,$$

of symbol $9\lambda^2-10\lambda+1=(9\lambda-1)(\lambda-1)$. The walls of the direction are all 1, so $V_1=3!=6$ (Proposition 39.34), and the low-end relation (Corollary 39.38(ii)) is $6-3P_3(1)+9P_3(2)=0$. So $P_3(1)=\ell$, $P_3(2)=\frac{\ell}{3}-\frac{2}{3}$, and the law gives

$$P_3(3)=\frac{5\ell}{27}-\frac{23}{54},\qquad P_3(4)=\frac{31\ell}{243}-\frac{145}{486},\qquad P_3(k)\in\mathbb{Q}+\mathbb{Q}\,\ell\quad(k\ge1).$$

The law of the squares. Write the law as $P_3(k+2)=a(k)P_3(k)+b(k)P_3(k+1)$; then $P_3(k+3)=a^{(1)}P_3(k)+b^{(1)}P_3(k+1)$ with $a^{(1)}=b(k+1)a(k)$ and $b^{(1)}=a(k+1)+b(k+1)b(k)$. The squares $x(k)=P_3(k)^2,\dots,x(k+3)$ are quadratic forms in $P_3(k),P_3(k+1)$, and the combination $d_0x(k)+d_1x(k+1)+d_2x(k+2)+x(k+3)$ with $d_2=-a^{(1)}b^{(1)}/(ab)$, $d_0=-d_2a^2-(a^{(1)})^2$, $d_1=-d_2b^2-(b^{(1)})^2$ vanishes identically. Cleared of denominators, the law of the centre ray of P_5 is $\sum_{i=0}^{3}d_i(k)\,x(k+i)=0$ with

$$\begin{gathered}d_0=k^4(10k^2+30k+23),\qquad d_3=-729(k+2)^4(10k^2+10k+3),\\ d_1=-(10k^2+10k+3)\,w(k),\qquad d_2=9(10k^2+30k+23)\,w(k),\\ w(k)=91k^4+364k^3+506k^2+284k+60,\end{gathered}$$

which the squares of the values above satisfy identically in ℓ at $k=1,\dots,5$. Its symbol is $-10(\lambda-1)(9\lambda-1)(81\lambda-1)$, the products of the roots $\frac19$ and 1 in pairs; $\frac{1}{81}=K(\mathbf{1})^{-2}$, $K(\mathbf{1})=9$ the number of bases. The walls of P_5 are 1 on single marks, on $\{1,2\}$ and on their complements, and 2 on the other sets of two or three marks, and $V_1=36$, the square of the 6 of $\binom{[3]}{1}$, as $P_3(k)^2\sim36k^{-4}$ at 0 requires. d_0 vanishes to order four at 0, $[k^4]d_0=23$, and the low-end relation

$$23\cdot36+d_1(0)\,x(1)+d_2(0)\,x(2)+d_3(0)\,x(3)=828-180\,x(1)+12420\,x(2)-34992\,x(3)=0$$

holds identically in ℓ at $x(i)=P_3(i)^2$. Every value $x(k)=P_3(k)^2$ lies in $\mathbb{Q}+\mathbb{Q}\,\ell+\mathbb{Q}\,\ell^2$. As a check, the procedure that reads a ray from its list by a box (Definition 41.8, Theorem 39.21), run on P_5 by the supplied reader, returns the same law and $P_{\mathrm{P}_5}(\mathbf{1};1,1)=5.4939011435808440124442576078206911958\ldots$, which is ℓ^2 to 87 digits.

(iii) $\binom{[4]}{2}$ *at its centre.* $\binom{[4]}{2}$ is identically self-dual: the complement of a pair is a pair, and the weights are 1. Corollary 20.19 at a mark, and Proposition 8.15 for the deletion $\binom{[3]}{2}$, give $q(\sigma) = \Gamma{}^{2}_{1}\!\left[\begin{smallmatrix}\sigma,\ \sigma\\ 2\sigma\end{smallmatrix}\right] P_3(\sigma) = P_2(\sigma)P_3(\sigma)$. With $P_2(\sigma{+}1)/P_2(\sigma) = \sigma/(2(2\sigma{+}1))$ (Proposition 1.3(iii)), the law of P_3 multiplied through by $\sigma P_2(\sigma)$ is the law of q:

$$\sigma^3 q(\sigma) - 2(2\sigma+1)(10\sigma^2+10\sigma+3)\,q(\sigma+1) + 36(\sigma+1)(2\sigma+1)(2\sigma+3)\,q(\sigma+2) = 0,$$

with the symbol $(4\lambda-1)(36\lambda-1)$ and $V_1 = 12 = 2\cdot 6$, the walls of $\binom{[4]}{2}$ being $1, 2, 1$ on sets of one, two and three marks.

(iv) The triangle rows. T_5 is H_4 of Section 55.1 with the class enlarged to $\{1,2,3\}$: the two-sum of the series cell $\mathcal{S}$ of $\{4,5\}$, with $f_{\mathcal{S}} = \mathsf{g}^2$ and $\kappa_{\mathcal{S}} = \sigma$, and the parallel cell $\mathcal{P}$ of $\{1,2,3\}$, with $\check{f}_{\mathcal{P}} = \mathsf{g}^3$ and $\kappa_{\mathcal{P}} = 3\sigma - 2\sigma = \sigma$ (Theorem 23.14). The root of three one-mark leaves (Definition 23.19(5)) gives $\int_0^\infty y^{z-1}\mathsf{g}^3 dy = \Gamma(z)^2 P_3(z)$, so Proposition 23.8(iii) gives $\int \varrho_{\mathcal{P}}^{z-\sigma} d\phi_{\mathcal{P}} = P_3(z)$, and $\int \varrho_{\mathcal{S}}^{-z} d\phi_{\mathcal{S}} = P_2(z)$ as in Exercise 55.1(iv). Theorem 23.9(iv) gives, for $0 < c < \sigma$,

$$\Gamma(\sigma)^2 P_{\mathrm{T}_5}(\sigma\mathbf{1};\sigma,\sigma) = \frac{1}{2\pi i}\int_{(c)} \Gamma(z)^2\,\Gamma(\sigma-z)^2\,q(z)\,dz.$$

$|q(z)| \le q(\operatorname{Re} z)$, the modulus of the integrand of a period being the integrand at the real parts, and $q(x) \le 4^{1-x}P_3(1)$ for $x \ge 1$; so the closing to the right of Exercise 55.1(iv) applies, the moved line contributing $O(N^{2s-2}4^{-N})$, and at an integer strength s

$$\Gamma(s)^2 P_{\mathrm{T}_5}(s\mathbf{1};s,s) = -\sum_{x\ge s} \big(V_s\,q\big)'(x), \qquad V_s(x) = \prod_{j=1}^{s-1}(x-j)^2.$$

At $s = 1$ this needs the slopes $q'(x) = P_2(x)\big(P_3'(x) + 2(h_{x-1} - h_{2x-1})P_3(x)\big)$. The law of P_3 holds as an identity of meromorphic functions, so its derivative in k holds as well and gives $P_3'(k+2)$ from $P_3'(k)$, $P_3'(k+1)$ and the values, starting from $P_3'(1) = \ell'$ and $P_3'(2)$. Near $k = 0$, $k^2 P_3(k) = 6 + \mathsf{L}_1 k + O(k^2)$ with $\mathsf{L}_1 = 0$ (Proposition 39.39, every weight being 1), so the derivative of the law at $k = 0$ reads $-10\ell - 3\ell' + 18P_3(2) + 9P_3'(2) = 0$:

$$P_3'(2) = \frac{4\ell}{9} + \frac{\ell'}{3} + \frac{4}{3}, \qquad P_3'(3) = \frac{26\ell}{81} + \frac{5\ell'}{27} + \frac{13}{18}, \qquad P_3'(k) \in \mathbb{Q} + \mathbb{Q}\,\ell + \mathbb{Q}\,\ell'.$$

So $P_{\mathrm{T}_5}(\mathbf{1};1,1) = -\sum_{x\ge1} q'(x) = a + b\,\ell + c\,\ell'$, where a, b, c are series of rational numbers whose terms decrease like 4^{-x}; summed to $x = 65$,

$$a = -0.46159963274916253008918\ldots, \qquad b = 2.01706417220768446716615\ldots,$$
$$c = -1.06282955174549612502149\ldots$$

With $\Gamma(\sigma)^2 P_3(\sigma) = \int_0^\infty y^{\sigma-1}\mathsf{g}(y)^3\,dy$, so that $\ell' = \int_0^\infty \log y\,\mathsf{g}^3 dy - 2(\log\Gamma)'(1)\,\ell$, quadrature gives

$$\ell = 2.34390723868945889060156228887227706909 54\ldots,$$
$$\ell' = -8.07515226353164401026965124146737650 13\ldots,$$

and

$$P_{\mathrm{T}_5}(\mathbf{1};1,1) = 12.84872214191555595731233993125353463661 9\ldots,$$

which the reading of T_5 by the box procedure (Definition 41.8) reproduces to 53 digits. For R_5 the series root has three cells, the mark 5, with the transform g, and the parallel cells of $\{1,2\}$

and $\{3,4\}$, each with the transform $f_{\mathcal{P}_2}$ whose Mellin transform is $\Gamma(w)^2 P_2(\sigma-w)$, $0<w<\sigma$ (Proposition 23.8(iii), with $\check{f}_{\mathcal{P}_2}=\mathsf{g}^2$); by Definition 23.19(5)

$$\Gamma(\sigma)^2 P_{\mathrm{R}_5}(\sigma\mathbf{1};\sigma,\sigma)=\int_0^\infty y^{\sigma-1}\,\mathsf{g}(y)\,f_{\mathcal{P}_2}(y)^2\,dy,$$

and the box procedure reads $P_{\mathrm{R}_5}(\mathbf{1};1,1)=7.865837368364021592421974697446 8210 9\ldots$

Answer. The trees are those listed in (i). $P_{\mathrm{P}_5}=P_3^2$, with the law $\sum_{i=0}^3 d_i(k)x(k+i)=0$ of symbol $-10(\lambda-1)(9\lambda-1)(81\lambda-1)$, $V_1=36$, the low-end relation $828-180x(1)+12420x(2)-34992x(3)=0$, and the value span $\mathbb{Q}+\mathbb{Q}\,\ell+\mathbb{Q}\,\ell^2$. $P_{\binom{[4]}{2}}=P_2P_3$ obeys $\sigma^3q(\sigma)-2(2\sigma+1)(10\sigma^2+10\sigma+3)q(\sigma+1)+36(\sigma+1)(2\sigma+1)(2\sigma+3)q(\sigma+2)=0$. $\Gamma(\sigma)^2P_{\mathrm{T}_5}(\sigma)=\frac{1}{2\pi i}\int\Gamma(z)^2\Gamma(\sigma-z)^2q(z)\,dz$ closes to the right, $\Gamma(s)^2P_{\mathrm{T}_5}(s)=-\sum_{x\geq s}(V_sq)'(x)$, and $P_{\mathrm{T}_5}(\mathbf{1};1,1)=a+b\,\ell+c\,\ell'=12.8487221419\ldots$ with the series a,b,c of (iv). □

55.3 Larger lists and the cost of a reading

Exercise 55.4 (The list N_6: letters and constant terms)**.** Let N_6 be the list of rank three on $\mathcal{E}=\{1,\ldots,6\}$ whose bases are the nineteen triples other than $a=\{1,2,3\}$, and put $b=\{4,5,6\}$. On a write $K_a=\alpha_1+\alpha_2+\alpha_3$, $\Psi_a=\alpha_1\alpha_2+\alpha_1\alpha_3+\alpha_2\alpha_3$ and $\alpha^a=\alpha_1\alpha_2\alpha_3$, the letters and the monomial of the list $\binom{a}{1}$, and K_b, Ψ_b, α^b the same on b.

(i) Show that the letters of N_6 are $K=Q+\alpha^b$ and $\Psi=Q+\alpha^a$, with $Q=\Psi_aK_b+K_a\Psi_b$.

(ii) For $i,l\in\mathbb{N}$ with $2i+l=3D$, $D\in\mathbb{N}$, let $\gamma_{i,l}$ be the coefficient of $\alpha_1^D\alpha_2^D\alpha_3^D$ in $\Psi_a^i\,K_a^l$. Show that

$$\gamma_{i,l}=\sum_w\binom{i}{w}\binom{l}{w+\frac{l-i}{3}}\binom{2D-2w}{D-w}.$$

(iii) The centre ray of N_6 at the strength 1 (Definition 38.13) has the direction $(\mathbf{1};1,1)$, and the ray with origin 0 and direction $(\mathbf{1};0,2)$, the full cobasis lean, has the stride $f=\alpha^{\mathcal{E}}\Psi^{-2}$. Write the constant terms $\mathrm{CT}(f^{-j})$ of the two reciprocal strides as sums of products of two numbers $\gamma_{i,l}$, and compute them for $j\leq 4$.

Solution. (i) A triple T other than a meets a in at most two marks. If it meets a in two marks it is a pair of a and a mark of b, and these monomials α^T add up to Ψ_aK_b; if it meets a in one mark it is a mark of a and a pair of b, which add up to $K_a\Psi_b$; if it meets a in no mark it is b. So $K=\sum_{T\in\mathcal{B}}\alpha^T=\Psi_aK_b+K_a\Psi_b+\alpha^b=Q+\alpha^b$. The cobases are the complements of the bases; the complement of a triple is a triple, and the complement of a is b, so the cobases are the triples other than b, and the same count with a and b exchanged gives $\Psi=\sum_{T\in\mathcal{B}}\alpha^{\mathcal{E}\setminus T}=\Psi_bK_a+K_b\Psi_a+\alpha^a=Q+\alpha^a$.

(ii) Write $\Psi_a=\alpha_1\alpha_2+\alpha_3(\alpha_1+\alpha_2)$ and $K_a=\alpha_3+(\alpha_1+\alpha_2)$. Take w of the i factors of Ψ_a^i equal to $\alpha_1\alpha_2$ and v of the l factors of K_a^l equal to α_3:

$$\Psi_a^iK_a^l=\sum_{w,v}\binom{i}{w}\binom{l}{v}(\alpha_1\alpha_2)^w\,\alpha_3^{\,i-w+v}\,(\alpha_1+\alpha_2)^{\,i-w+l-v}.$$

The power D of α_3 asks $v=D-i+w=w+\frac{l-i}{3}$, since $D-i=\frac{2i+l}{3}-i$. Then $i-w+l-v=2i+l-D-2w=2D-2w$, and the coefficient of $\alpha_1^{D-w}\alpha_2^{D-w}$ in $(\alpha_1+\alpha_2)^{2D-2w}$ is $\binom{2D-2w}{D-w}$, which gives the formula. The first values are

$$\gamma_{0,0}=1,\quad \gamma_{1,1}=3,\quad \gamma_{3,0}=\gamma_{0,3}=6,\quad \gamma_{2,2}=15,\quad \gamma_{4,1}=\gamma_{1,4}=36,\quad \gamma_{3,3}=93;$$

for instance $\gamma_{2,2} = \binom{2}{0}\binom{2}{0}\binom{4}{2} + \binom{2}{1}\binom{2}{1}\binom{2}{1} + \binom{2}{2}\binom{2}{2}\binom{0}{0} = 6 + 8 + 1$. Each $\gamma_{i,l}$ is the constant term $\mathrm{CT}\left(\alpha^{-D\mathbf{1}}\Psi_a^i K_a^l\right)$ on $\binom{a}{1}$: the first constant term of the three-mark ray with direction $(D\mathbf{1}; l, i)$.

(iii) *The centre.* The stride is $f = \alpha^{\mathcal{E}}(K\Psi)^{-1}$ (Definition 38.13), so $\mathrm{CT}(f^{-j})$ is the coefficient of $\alpha^{j\mathbf{1}}$ in $(K\Psi)^j$; every letter exponent of the direction is 1, and this is the closing $\mathsf{C}_j(1)$ of Definition 39.30. Expand $K^j = (\Psi_a K_b + K_a \Psi_b + \alpha^b)^j$ with u_1, u_2, u_3 factors of the three kinds and $\Psi^j = (K_a\Psi_b + \Psi_a K_b + \alpha^a)^j$ with v_1, v_2, v_3. The product splits into a part on a and a part on b,

$$\Psi_a^{u_1+v_2} K_a^{u_2+v_1} (\alpha^a)^{v_3} \cdot \Psi_b^{u_2+v_1} K_b^{u_1+v_2} (\alpha^b)^{u_3},$$

and the coefficient of $\alpha^{j\mathbf{1}}$ is the product of the coefficient of $\alpha_1^{j-v_3}\alpha_2^{j-v_3}\alpha_3^{j-v_3}$ in the first factor without $(\alpha^a)^{v_3}$ and the like coefficient on b. Put $p = j - u_3 = u_1 + u_2$, $q = j - v_3 = v_1 + v_2$, $i = u_1 + v_2$ and $l = u_2 + v_1$. The degrees ask $2i + l = 3q$ and $i + 2l = 3p$, that is $i = 2q - p$ and $l = 2p - q$, and the two coefficients are $\gamma_{2q-p,\,2p-q}$ and $\gamma_{2p-q,\,2q-p}$. The multinomial weights summed over u_1, with $u_2 = p - u_1$, $v_2 = i - u_1$, $v_1 = q - i + u_1$, give

$$\sum_{u_1} \frac{j!}{u_1!\,u_2!\,u_3!} \cdot \frac{j!}{v_1!\,v_2!\,v_3!} = \binom{j}{p}\binom{j}{q}\sum_{u_1}\binom{p}{u_1}\binom{q}{i-u_1} = \binom{j}{p}\binom{j}{q}\binom{p+q}{2q-p}$$

by Vandermonde's identity. So

$$\mathrm{CT}(f^{-j}) = \sum_{p,q=0}^{j} \binom{j}{p}\binom{j}{q}\binom{p+q}{2q-p}\,\gamma_{2q-p,\,2p-q}\,\gamma_{2p-q,\,2q-p}.$$

At $j = 1$ the terms $(p, q) = (0, 0)$ and $(1, 1)$ survive, $1 + 2 \cdot 3 \cdot 3 = 19$, the number of bases. At $j = 2$ the terms $(0, 0)$, $(1, 1)$, $(1, 2)$, $(2, 1)$, $(2, 2)$ are

$$1 + 2 \cdot 2 \cdot 2 \cdot 3 \cdot 3 + 2 \cdot 1 \cdot 1 \cdot 6 \cdot 6 + 1 \cdot 2 \cdot 1 \cdot 6 \cdot 6 + 1 \cdot 1 \cdot 6 \cdot 15 \cdot 15 = 1 + 72 + 72 + 72 + 1350 = 1567,$$

and at $j = 3$ the eight terms $(0,0), (1,1), (1,2), (2,1), (2,2), (2,3), (3,2), (3,3)$ are $1 + 162 + 324 + 324 + 12150 + 19440 + 19440 + 172980 = 224821$.

The full cobasis lean. Here $f^{-1} = \Psi^2/\alpha^{\mathcal{E}}$, and $\mathrm{CT}(f^{-j})$ is the coefficient of $\alpha^{j\mathbf{1}}$ in Ψ^{2j}; the direction has the letter exponent $s = 0$, so Definition 39.30 does not apply and the constant term is taken as written. With v_1, v_2, v_3 factors $K_a\Psi_b$, $\Psi_a K_b$, α^a out of $2j$ and $p = v_1 + v_2$, the part on b is $\Psi_b^{v_1} K_b^{v_2}$, of degree $3j$, so $2v_1 + v_2 = 3j$: $v_1 = 3j - p$ and $v_2 = 2p - 3j$; the part on a is $K_a^{v_1}\Psi_a^{v_2}(\alpha^a)^{v_3}$ with $v_3 = 2j - p$. So

$$\mathrm{CT}(f^{-j}) = \sum_{p} \binom{2j}{p}\binom{p}{2p-3j}\,\gamma_{2p-3j,\,3j-p}\,\gamma_{3j-p,\,2p-3j}.$$

At $j = 1$ only $p = 2$ survives: $\binom{2}{2}\binom{2}{1}\gamma_{1,1}^2 = 18$, the bases whose complement is a basis, all but b. At $j = 2$, $p = 3$ and $p = 4$ give $\binom{4}{3}\binom{3}{3}\gamma_{0,3}\gamma_{3,0} + \binom{4}{4}\binom{4}{2}\gamma_{2,2}^2 = 144 + 1350 = 1494$, and at $j = 3$, $p = 5$ and $p = 6$ give $\binom{6}{5}\binom{5}{1}\gamma_{1,4}\gamma_{4,1} + \binom{6}{6}\binom{6}{3}\gamma_{3,3}^2 = 38880 + 172980 = 211860$.

The closing values for $j \le 4$, by the two formulas and, as a check, by expanding $(K\Psi)^j$ and Ψ^{2j} with every exponent above j dropped (receipt `nsix_exact.py`), are

j	0	1	2	3	4
centre $(\mathbf{1}; 1, 1)$	1	19	1567	224821	41485807
lean $(\mathbf{1}; 0, 2)$	1	18	1494	211860	38486070

So the constant terms of N_6 are sums of products of two first constant terms of the three-mark list $\binom{[3]}{1}$ along its directions $(D\mathbf{1}; l, i)$, one factor for each of the triples a and b; the sums cost $O(j^2)$ and $O(j)$ products of numbers $\gamma_{i,l}$, each a sum of $O(j)$ terms. □

Exercise 55.5 (N_6 at its full cobasis lean)**.** Read the ray of N_6 (Exercise 55.4) with origin 0 and direction $(\mathbf{1};0,2)$, whose stride is $f=\alpha^{\mathcal{E}}\Psi^{-2}$, by the procedure of Definition 41.8:

(i) its walls and the volume V_1 of its direction;

(ii) the native gauge $\alpha^\star$ of the direction, $f^\star=f(\alpha^\star)$ and the Hessian H there;

(iii) the box with one unit of each active letter, its spanning set and its matrix $\mathbf{B}$, the matrix at infinite strength and its spectrum, and that the spanning set is a set of masters;

(iv) the law of [1], its two end coefficients, its symbol, and the strengths at which its rows line up;

(v) the low-end relation and the constant terms;

(vi) the value $\langle 1\rangle_1=P_{\mathrm{N}_6}(\mathbf{1};0,2)$.

Solution. Throughout, S is a nonempty proper subset of $\mathcal{E}$, $r(S)$ the largest trace of a basis on S, and the *type* of S is the pair $(i,j)=(|S\cap a|,|S\cap b|)$.

(i) *Walls.* By Definition 8.1 the walls of the direction are $\kappa_{1,S}=m_{1,S}-s\,d(S)-t\,d^*(S)$, with $d(S)$ and $d^*(S)$ the least traces of a basis and of a cobasis on S. Here $m_1=\mathbf{1}$, $s=0$, $t=2$, and the least trace of a cobasis is $d^*(S)=|S|-r(S)$, so

$$\kappa_{1,S}=2\,r(S)-|S|.$$

The rank of N_6 is $r(S)=\min(|S|,3)$, except $r(a)=2$, so $\kappa_{1,S}$ depends on the type alone:

(i,j)	$(1,0)$	$(0,1)$	$(2,0)$	$(1,1)$	$(0,2)$	$(3,0)$	$(2,1)$
$\kappa_{1,S}$	1	1	2	2	2	1	3
$F(i,j)$	1	1	1	1	1	3	1

(i,j)	$(1,2)$	$(0,3)$	$(3,1)$	$(2,2)$	$(1,3)$	$(3,2)$	$(2,3)$
$\kappa_{1,S}$	3	3	2	2	2	1	1
$F(i,j)$	1	1	3	2	2	12	10

Every wall is positive, the least is 1: the direction is strictly inside its walls, and counted with the sizes of the types the 62 walls are 1 thirteen times, 2 thirty times and 3 nineteen times.

The volume. By Proposition 39.34, $V_1=\sum_\pi\prod_{l=2}^{6}\kappa_{1,U_l}^{-1}$ over the orders π of $\mathcal{E}$ with their tails $U_l=\{\pi(l),\dots,\pi(6)\}$. An order is a chain of tails $U_6\subset\cdots\subset U_2$, so $V_1=\sum_e F(\mathcal{E}\setminus\{e\})$ with $F(\{e\})=\kappa_{1,\{e\}}^{-1}$ and $F(U)=\kappa_{1,U}^{-1}\sum_{e\in U}F(U\setminus\{e\})$. F depends on the type alone, $F(i,j)=\kappa_{1,(i,j)}^{-1}\big(i\,F(i-1,j)+j\,F(i,j-1)\big)$, which gives the last row of the table: for instance $F(3,0)=1^{-1}\cdot 3\,F(2,0)=3$, $F(3,1)=2^{-1}\big(3F(2,1)+F(3,0)\big)=3$, $F(3,2)=1^{-1}\big(3F(2,2)+2F(3,1)\big)=12$ and $F(2,3)=1^{-1}\big(2F(1,3)+3F(2,2)\big)=10$. So

$$V_1=3\,F(2,3)+3\,F(3,2)=30+36=66.$$

(ii) *The native gauge.* By Theorem 38.14(i), $f\le f(\alpha^\star)$ on the positive orthant with equality only at $\alpha\propto\alpha^\star$. The 36 automorphisms of N_6, the permutations of a and of b, keep the masses $\mathbf{1}$ and the exponents, so they are symmetries of the ray (Proposition 39.11(ii)); they keep f and the orthant and therefore fix $\alpha^\star$ up to scale. On the chart $\alpha_6=1$ this puts $\alpha^\star$ on the slice $\alpha=(x,x,x,1,1,1)$, where $Q=3x^2\cdot 3+3x\cdot 3$, $\Psi=x^3+9x^2+9x$ and

$$f=\frac{x^3}{x^2(x^2+9x+9)^2}=\frac{x}{(x^2+9x+9)^2},\qquad \frac{d}{dx}\log f=-\frac{3(x^2+3x-3)}{x(x^2+9x+9)}.$$

So $\alpha^\star = (x^\star, x^\star, x^\star, 1, 1, 1)$ with $x^\star = \frac{\sqrt{21}-3}{2}$, and with $x^2 = 3 - 3x$, $x^2 + 9x + 9 = 6(x + 2)$ and $f = x/(36(x + 2)^2)$ there:

$$f^\star = \frac{7\sqrt{21} - 27}{1800} = 0.0028211277026060444701\ldots$$

At a complex point fixed by the automorphisms the differential of $\log f$ in $y = \log \alpha$ is fixed by them too, so it is constant on a and on b, (u, u, u, v, v, v), and $u+v = 0$ because f is homogeneous of degree 0; it vanishes as soon as its derivative along the slice, $3u$, does. So the other root $x' = -\frac{\sqrt{21}+3}{2}$ gives a native gauge $\alpha' = (x', x', x', 1, 1, 1)$ too (Definition 38.4), at which $K = 9x'^2 + 9x' + 1$ and $\Psi = 6x'(x' + 2)$ do not vanish, of the conjugate native value $-\frac{7\sqrt{21}+27}{1800}$. The Hessian of $-\log f$ at $\log \alpha^\star$ on the chart is $H = 2\big(\kappa_{\alpha^\star}(X_e, X_{e'})\big)_{e,e' \neq 6}$, twice the covariances of the indicators under the cobasis law at $\alpha^\star$ (Theorem 38.15); computed in $\mathbb{Q}(\sqrt{21})$ (receipt `hessians.py`),

$$\det H = \frac{13049\sqrt{21} - 59339}{37500} = 0.0122408064927668332\ldots$$

(iii) *The box* (Procedure 41.8, the masters). The letter K has the exponent 0 along the ray and Ψ the exponent $2k$, so only Ψ is active, and the box with one unit of each active letter is $\mathfrak{B}_2(0, 1)$ of Definition 39.15(iv): the symbols of wall degree at most 2 at the levels $(0, 0)$ and $(0, 1)$; its stems are the Laurent symbols of wall degree at most 2. The 36 automorphisms keep it (Definition 39.15(vi)), and modulo them (Definition 39.20(i)) there are 104 orbits of stems and 329 orbits of symbols; the relations are the 104 letter identities $\alpha^u - \sum_T \alpha^{u+\mathbf{1}\varepsilon\setminus T}\Psi^{-1}$ of the stems and their $104 \cdot 6 = 624$ mark relations, 728 in all. One elimination, the orbits ranked as in Definition 39.20(ii), done modulo a prime of 61 bits at a random strength, which gives the pivots over $\mathbb{Q}(k)$ off finitely many strengths, leaves free among the Laurent orbits of wall degree at most 1 those of the seven orbit averages

$$b_1 = 1, \quad b_2 = \Big[\frac{\alpha_3\alpha_5\alpha_6}{\alpha_1\alpha_2\alpha_4}\Big], \quad b_3 = \Big[\frac{\alpha_3\alpha_6}{\alpha_1\alpha_2}\Big], \quad b_4 = \Big[\frac{\alpha_5\alpha_6}{\alpha_1\alpha_4}\Big],$$
$$b_5 = \Big[\frac{\alpha_6}{\alpha_1}\Big], \quad b_6 = \Big[\frac{\alpha_3\alpha_6}{\alpha_1\alpha_4}\Big], \quad b_7 = \Big[\frac{\alpha_2\alpha_3\alpha_6}{\alpha_1\alpha_4\alpha_5}\Big],$$

$[\,\cdot\,]$ the average over the 36 automorphisms, of wall degree 0 and 1 (Proposition 39.16(ii): the wall degree of α^u is $\max_U(-u_U)/\kappa_{1,U}$; for $b_2, \ldots, b_7$ it is 1, reached at $U = \{1\}$), and every target $f^{-1}b_i$, of wall degree at most 2, reduces to them. So the box is accepted at $\mathfrak{s} = 1$ (Definition 39.20(iii)), and by Theorem 39.21(i) $[f^{-1}b_i] = \sum_l \mathbf{B}_{il}(k)[b_l]$ in the module, the classes of $b_1, \ldots, b_7$ spanning a submodule $\mathfrak{N}$ that contains $[1]$.

The matrix (Procedure 41.8, the matrix over $\mathbb{Q}(k)$). Input: the 728 relations, with coefficients $c_0 + c_1 k$, $c_0, c_1 \in \mathbb{Z}$. Method: the targets need 292 of them, of rank 292; eliminations modulo primes of 62 bits at random strengths, 24 strengths on the first prime, every entry read as a quotient of polynomials, and Chinese remaindering with rational reconstruction over three primes. Output: the common denominator of the entries is $Q_c = (k - 2)^5(k + 1)$, and the row i of $\mathbf{B}$ is a factor ϕ_i times a row of polynomials:

i	ϕ_i	$\mathbf{B}_{il}/\phi_i$, $l = 1, \ldots, 7$
1	$\frac{6(2k-1)}{(k-2)(k+1)}$	6; $4(k-2)$; $6(k-1)$; $6(k-1)$; $8(k+1)$; -24; $-(k+1)$
2	$\frac{2(k-1)(2k-1)}{(k-2)^5(k+1)}$	$k^4 + 20k^3 - 36k^2 + 40k - 16$; $2k(k-2)(8k^2 - 19k + 10)$; $2k(12k^3 - 37k^2 + 42k - 20)$; $2k(12k^3 - 37k^2 + 42k - 20)$; $4k(k+1)(8k^2 - 12k + 9)$; $-4(k^4 + 20k^3 - 48k^2 + 36k - 8)$; $-8(k-1)^3(k+1)$

3	$\frac{2(k-1)(2k-1)}{(k-2)^4(k+1)}$	$-2k^3+33k^2-42k+16$; $(k-2)(15k^2-33k+14)$; $25k^3-75k^2+70k-16$; $19k^3-57k^2+70k-40$; $2k(k+1)(14k-11)$; $4(2k^3-27k^2+44k-20)$; $-(k-1)(k+1)(5k-6)$
4	$\frac{2(k-1)(2k-1)}{(k-2)^4(k+1)}$	the row 3 with its third and fourth entries exchanged
5	$\frac{2(k-1)(2k-1)}{(k-2)^3(k+1)}$	$24(k-1)$; $4(k-2)(3k-5)$; $2(9k^2-23k+16)$; $2(9k^2-23k+16)$; $(k+1)(33k-32)$; $4(3k^2-23k+22)$; $-(k+1)(3k-4)$
6	$\frac{2(k-1)(2k-1)}{(k-2)^4(k+1)}$	$2k^3+11k^2-26k+16$; $(k-2)(k-1)(7k-10)$; $13k^3-41k^2+40k-8$; $13k^3-41k^2+40k-8$; $(k+1)(33k^2-73k+48)$; $4(k^3-13k^2+23k-14)$; $-(k+1)(k^2-2)$
7	$\frac{2(k-1)(2k-1)}{(k-2)^5(k+1)}$	$-2k^4+23k^3-44k^2+53k-16$; $(k-2)(k-1)^2(16k-7)$; $27k^4-94k^3+99k^2-34k+22$; $27k^4-94k^3+99k^2-34k+22$; $(k+1)(8k^3+17k^2-35k+32)$; $-13k^4-39k^3+231k^2-273k+22$; $-(k+1)(17k^3-80k^2+131k-73)$

Check: **B** agrees with an elimination of the whole box at a prime and a strength drawn at random, and again at three fresh ones. Receipt: `rayreader.py N "1 1 1 1 1 1 ; 0 2"`, read by `analyze_run.py` and `matrix_rows_tex.py`; the re-check by `tests/check_run.py`.

Infinite strength. Every entry has a numerator of degree at most that of its denominator, so **B** is regular at $k=\infty$, with

$$\mathbf{B}(\infty)=\begin{pmatrix} 0 & 48 & 72 & 72 & 96 & 0 & -12\\ 4 & 64 & 96 & 96 & 128 & -16 & -32\\ -8 & 60 & 100 & 76 & 112 & 32 & -20\\ -8 & 60 & 76 & 100 & 112 & 32 & -20\\ 0 & 48 & 72 & 72 & 132 & 48 & -12\\ 8 & 28 & 52 & 52 & 132 & 16 & -4\\ -8 & 64 & 108 & 108 & 32 & -52 & -68 \end{pmatrix},$$

$$\det\big(\lambda-\mathbf{B}(\infty)\big)=(\lambda-24)^2\,(\lambda^2-324\lambda-10800)\,(\lambda^3+28\lambda^2-320\lambda+1728).$$

By Proposition 39.42(ii), at every nondegenerate native gauge α_c the vector $\beta_c=(b_l(\alpha_c))_l$ is an eigenvector of $\mathbf{B}(\infty)$ for $f(\alpha_c)^{-1}$. At $\alpha^\star$ every monomial of the orbit of α^u takes the value $(x^\star)^{u_1+u_2+u_3}$, so $\beta_\star=(1,\frac{1}{x^\star},\frac{1}{x^\star},\frac{1}{x^\star},\frac{1}{x^\star},1,x^\star)$ with $\frac{1}{x^\star}=\frac{\sqrt{21}+3}{6}$; the first row gives

$$\frac{48+72+72+96}{x^\star}-12x^\star=48(\sqrt{21}+3)-6(\sqrt{21}-3)=162+42\sqrt{21}=\frac{1800}{7\sqrt{21}-27}=\frac{1}{f^\star},$$

and the other rows the same, exactly. The eigenvalue 24 belongs to two rational native gauges: at $\alpha=(-1,\frac{3}{2},-1,1,1,1)$ and at $\alpha=(-1,-1,-1,1,-\frac{2}{3},1)$ every dual occupation is $R_e^*=\frac{1}{2}$, so every defect $1-2R_e^*$ vanishes, $f=\frac{1}{24}$, and the Hessian of $\log f$ on the chart has the determinant $\frac{625}{864}$ at both; their vectors

$$\beta=\big(1,\tfrac{17}{18},\tfrac{17}{18},-\tfrac{4}{9},-\tfrac{4}{9},-\tfrac{7}{18},\tfrac{11}{9}\big),\qquad \beta'=\big(1,\tfrac{17}{18},-\tfrac{4}{9},\tfrac{17}{18},-\tfrac{4}{9},-\tfrac{7}{18},\tfrac{11}{9}\big)$$

satisfy $\mathbf{B}(\infty)\beta=24\beta$ and $\mathbf{B}(\infty)\beta'=24\beta'$ exactly, and are independent. Receipt: `nsix_gauges24.py`.

The native gauges and the masters. Input: the critical equations $1-2R_e^*(\alpha)=0$ on the chart, saturated by the coordinates and the letters. Method: a Groebner basis over $\mathbb{Q}$, and, separately, the critical points of $\alpha^{\mathbf{a}}\Psi^{-b}$ for random complex exponents counted by monodromy and carried to $(\mathbf{1};2)$. Output: the ideal is zero-dimensional with 35 points counted with multiplicity, and the 35

native gauges found by the paths are distinct and nondegenerate, in 7 orbits of the automorphisms of sizes $1,1,3,3,9,9,9$: $\alpha^\star$, α', the two rational orbits of native value $\frac{1}{24}$, and three orbits whose native values are the roots of $1728\lambda^3 - 320\lambda^2 + 28\lambda + 1$, the real one $-0.0265230928\ldots$ and $0.1058541390\ldots \pm 0.1030231201\ldots\, i$. Check: Newton's method at 40 digits at each point, residual below 10^{-38}; the seven vectors β_c, one per orbit, have the singular values from 8.93 down to 0.358, and each is an eigenvector of $\mathbf{B}(\infty)$ to 10^{-38}. Receipts: `gb_direction.py`, `critpoints.py`, `polish.py`, `betas.py`. So the vectors β_c span $\mathbb{C}^7$, and by Proposition 39.42(i) the spanning set is a set of masters of $\mathfrak{N}$: $\dim_{\mathbb{C}(k)} \mathfrak{N} = 7$, $\mathbf{B} = \mathbf{B_b}$, and $\mathbf{B}(\infty)$ is diagonalizable with the eigenvalues $f(\alpha_c)^{-1}$, 24 twice for the two orbits of native value $\frac{1}{24}$.

(iv) *The law* (Procedure 41.8, the law). Input: $\mathbf{B}$. Method: the rows $w_0 = (1,0,\ldots,0)$, $w_i(k) = w_{i-1}(k-1)\,\mathbf{B}(k)$ of Proposition 39.6, evaluated modulo primes at consecutive strengths; their first dependence; the coefficients reconstructed over $\mathbb{Q}$ from four primes and made integral and primitive. Output: $w_0,\ldots,w_5$ are independent and $w_0,\ldots,w_6$ dependent, so $h = 6$, and the relation $\sum_{j=0}^{6} c_j(k)\langle 1\rangle_{k+j} = 0$ of Proposition 39.6(ii) has $c_j \in \mathbb{Z}[k]$ of degree 24, with coefficients of up to 31 digits. Check: the relation holds at a prime and a point drawn at random, and at three fresh ones. Since $b_1,\ldots,b_7$ are masters, Proposition 39.6(ii) makes it the law of [1] (Definition 39.1): the cyclic submodule of [1] has dimension 6, inside $\mathfrak{N}$ of dimension 7. Factored over $\mathbb{Q}$,

$$c_0 = k^5(k+1)^3(k+2)(k+3)\,r(k),$$
$$c_6 = 6998400\,(2k+1)(2k+3)(2k+5)(2k+7)(2k+9)(2k+11)(k+4)(k+5)^3\,r(k-1),$$

with r irreducible of degree 14 and integer coefficients of up to 18 digits, and the symbol (Corollary 38.7), the coefficients of k^{24},

$$\chi(\lambda) = 7276255875\,(24\lambda-1)(10800\lambda^2+324\lambda-1)(1728\lambda^3-320\lambda^2+28\lambda+1).$$

Its six roots are $\frac{1}{24}$, $f^\star$ and its conjugate (the roots of $10800\lambda^2+324\lambda-1$, $\frac{-27\pm7\sqrt{21}}{1800}$), and the three roots of the cubic: the six distinct native values of (iii), as Corollary 38.7 asks, and the reciprocals of the eigenvalues of $\mathbf{B}(\infty)$, 24 counted once.

Line-up strengths. In the notation of Proposition 39.6, $p_j = c_j$ and $q_6(k) = c_0(k-6)$, and Proposition 39.6(iii) gives

$$c_0(k-6) \;\Big|\; \det \mathbf{W}(k)_J \prod_{j=0}^{5} Q_c(k-j)^{6-j}, \qquad Q_c = (k-2)^5(k+1),$$

for every set J of six columns with $\det \mathbf{W}_J \neq 0$. The irreducible factor $r(k-6)$, of degree 14, divides no linear factor $Q_c(k-j)$, so it divides $\det \mathbf{W}(k)_J$: at its fourteen roots, none a root of a $Q_c(k-j)$, the rows $w_0,\ldots,w_5$ are dependent. So 14 of the 24 degrees of c_0 are strengths at which $\langle 1\rangle_k,\ldots,\langle 1\rangle_{k-5}$, read as linear forms in the values of the masters, line up; the other 10 are the integers $0,-1,-2,-3$.

(v) *The low end.* By Corollary 39.38(ii), c_0 vanishes to order $n-1=5$ at $k=0$, as it does, and with $\mathsf{L}_0 = V_1 = 66$ (Definition 39.37) the low-end relation $[k^5]c_0 \cdot 66 + \sum_{i=1}^{6} c_i(0)\langle 1\rangle_i = 0$, divided by 91238400, reads

$$64402904777 - 12632598108\,\langle 1\rangle_1 - 2849737197672\,\langle 1\rangle_2 + 380837271432240\,\langle 1\rangle_3$$
$$+ 14853466134400320\,\langle 1\rangle_4 - 369781615117353600\,\langle 1\rangle_5 + 3400346988339840000\,\langle 1\rangle_6 = 0.$$

By Corollary 39.38(i) the constant terms obey $\sum_{i=0}^{\min(6,j)} c_i(-j)\,\mathrm{CT}(f^{i-j}) = 0$ for every $j \in \mathbb{N}$; with the constant terms of Exercise 55.4 this holds exactly for $0 \le j \le 60$ (receipt `nsix_ctcheck.py`), a check of the law that uses neither the box nor the values.

(vi) *The value* (Procedure 41.8, the value). By Theorem 40.6 the values are the moments $\langle 1\rangle_k = \int_0^{f^\star} t^k \varrho_f(t)\,dt$ of the density ϱ_f of the stride's law (Definition 40.1); $f^\star$ is a simple root of χ, the density operator of the law has order 24, its exponent at $f^\star$ beyond $0,\dots,22$ is $\frac{n-3}{2} = \frac{3}{2}$, and the germ of ϱ_f is $(f^\star - t)^{3/2} g(f^\star - t)$ with g fixed by $g(0) = \big(2\Gamma(\frac12)^2/f^\star\big)^{5/2}\big/\big(\Gamma(\frac52)\sqrt{\det H}\big)$, the constant of the branch of Theorem 38.15. Input: the law, $f^\star$ and $\det H$. Method: the germ to 168 terms, the Beta sums $\int_0^{f^\star} t^K (f^\star - t)^{\frac32+m} dt = (f^\star)^{K+\frac52+m}\Gamma\,{}_2_1\!\left[\begin{matrix} K+1,\ \frac52+m \\ K+\frac72+m \end{matrix}\right]$ at the six strengths from $K = 57$ on, and the law run back to $k = 1$, in ball arithmetic at 1188 bits; again from $K = 82$. Output:

$$P_{\mathrm{N}_6}(\mathbf{1}; 0, 2) = \langle 1\rangle_1 = 4.75680256375822944340803728605708\ldots,$$

the two starting strengths agreeing to 50 digits. Check: the exponent read from the law at $f^\star$ is $\frac32$ to 16 digits; the reading at 700 digits of Exercise 55.7 agrees with this value, and on its values $\langle 1\rangle_1, \dots, \langle 1\rangle_6$ the low-end relation of (v), which the reading does not use, holds to 731 digits relative to its largest term. Receipt: `rayreader.py N "1 1 1 1 1 1 ; 0 2" --digits 30`.

So N_6 at $(\mathbf{1}; 0, 2)$ has the volume $V_1 = 66$, the native value $f^\star = \frac{7\sqrt{21}-27}{1800}$, seven masters with $\mathbf{B}(\infty)$ of spectrum $\{24, 24\}$, the reciprocals of the roots of $10800\lambda^2 + 324\lambda - 1$ and of $1728\lambda^3 - 320\lambda^2 + 28\lambda + 1$, a law of order 6 and degree 24, and the value $P_{\mathrm{N}_6}(\mathbf{1}; 0, 2) = 4.7568025637582294434\ldots$, with $P/V_1 = 0.0720727\ldots$ □

Exercise 55.6 (N_6 at its centre)**.** Read the centre ray of N_6 at the strength 1, with the direction $(\mathbf{1}; 1, 1)$ and the stride $f = \alpha^{\mathcal{E}}(K\Psi)^{-1}$, by the procedure of Definition 41.8: its walls and V_1; the native gauge of the direction and the signs; the box, the spanning set and its matrix at infinite strength; the law of [1], its ends, its symbol and its line-up strengths; the low-end relation, the closings and the value.

Solution. Walls and volume. With $m_1 = \mathbf{1}$ and $s = t = 1$, Definition 8.1 and $d(S) = 3 - r(\mathcal{E} \setminus S)$, $d^*(S) = |S| - r(S)$ give $\kappa_{1,S} = r(S) + r(\mathcal{E}\setminus S) - 3$, which depends on the type $(i, j) = (|S\cap a|, |S\cap b|)$ alone. With the recursion of Exercise 55.5(i):

(i,j)	$(1,0)$	$(0,1)$	$(2,0)$	$(1,1)$	$(0,2)$	$(3,0)$	$(2,1)$
$\kappa_{1,S}$	1	1	2	2	2	2	3
$F(i,j)$	1	1	1	1	1	$\frac32$	1

(i,j)	$(1,2)$	$(0,3)$	$(3,1)$	$(2,2)$	$(1,3)$	$(3,2)$	$(2,3)$
$\kappa_{1,S}$	3	2	2	2	2	1	1
$F(i,j)$	1	$\frac32$	$\frac94$	2	$\frac94$	$\frac{21}{2}$	$\frac{21}{2}$

Every wall is positive: 1 twelve times, 2 thirty-two times and 3 eighteen times, the triples a and b having the wall 2. By Proposition 39.34,

$$V_1 = 3\,F(2,3) + 3\,F(3,2) = \tfrac{63}{2} + \tfrac{63}{2} = 63.$$

The native gauge and the signs. On the centre ray $\alpha^\star = \mathbf{1}$ and $f^\star = K(\mathbf{1})^{-2} = 19^{-2} = \frac{1}{361}$ (Theorem 38.14, Definition 38.13), and $H = 2\big(\kappa_{\mathbf{1}}(X_e, X_{e'})\big)_{e,e'\neq 6}$, the covariances under the weight law, which is uniform on the nineteen bases (Theorem 38.15): each mark of a lies in 9 bases and each mark of b in 10, and

$$H = \frac{1}{361}\begin{pmatrix} 180 & -48 & -48 & -28 & -28 \\ -48 & 180 & -48 & -28 & -28 \\ -48 & -48 & 180 & -28 & -28 \\ -28 & -28 & -28 & 180 & -48 \\ -28 & -28 & -28 & -48 & 180 \end{pmatrix}, \qquad \det H = \frac{580608}{361^3}.$$

By Theorem 38.17(ii) every sign η with $K(\eta) \neq 0$ is a native gauge of native value $K(\eta)^{-2}$. A sign is fixed by its partition of the marks into the scales 1 and -1, and the 32 signs of the chart $\eta_6 = 1$ fall into eight orbits of the automorphisms: $K(\eta) = 19$ when all scales agree; $|K(\eta)| = 5$ when two marks of a, or two marks of b, stand against the other four, two orbits of three signs; $|K(\eta)| = 3$ when one mark of a and one of b stand against the other four, nine signs; and $|K(\eta)| = 1$ on the other four orbits, one mark against five (3 and 3 signs), a against b (1), and two marks of a with one of b against the rest (9). The Hessian of $\log f$ at a sign, in the chart $\alpha_e = \eta_e e^{y_e}$, has the determinants $-\frac{580608}{361^3}$, $\frac{9216}{15625}$, $\frac{1024}{729}$ at the first three kinds and 0 at the last: the native values $\frac{1}{361}$, $\frac{1}{25}$ (two orbits) and $\frac{1}{9}$ are nondegenerate, and the native value 1 is degenerate at every sign (receipt `nsix_signs.py`). On the slice $(x, x, x, 1, 1, 1)$, fixed by the automorphisms, $f = x^2/\big((x^2+9x+9)(9x^2+9x+1)\big)$ and $\frac{d}{dx}\log f$ has the numerator $-18(x-1)(x+1)(x^2+5x+1)$; as at the lean, a critical point of the slice is a native gauge, and $x^2 + 5x + 1 = 0$ gives the two native gauges $\big(\frac{-5\pm\sqrt{21}}{2}\big)$ of native value $-\frac{1}{80}$, exchanged by the Cremona.

The box (Procedure 41.8, the masters). Both letters are active, and the symmetries are the 36 automorphisms and the Cremona (Proposition 39.11), 72 maps, which keep every box with equal level bounds. The box $\mathfrak{B}_2(1,1)$ is not accepted: at $\mathfrak{s} = 1$ eight Laurent orbits are free and seven of their targets do not reduce to them, and at $\mathfrak{s} = 0$ the target of 1 does not reduce. The box $\mathfrak{B}_3(1,1)$ has 252 orbits of stems and 1909 orbits of symbols, and 3774 relations: the letter identities of the symbols at the levels $(0,0)$, $(1,0)$ and $(0,1)$ and the $252 \cdot 6$ mark relations of the stems. It is accepted at $\mathfrak{s} = 2$, with the spanning set of the fifteen averages, over the 72 maps, of 1 and of α^u for

$$\begin{gathered} u = (-1,-1,0,0,1,1),\ (-1,-1,1,-1,1,1),\ (-1,-1,1,0,0,1),\ (-1,0,0,-1,1,1), \\ (-1,0,0,0,0,1),\ (-1,0,1,-1,0,1),\ (-1,0,1,0,0,0),\ (-1,-1,-1,1,1,1), \\ (-2,-2,0,0,2,2),\ (-2,-2,0,1,1,2),\ (-2,-2,1,-1,2,2), \\ (-2,-2,1,0,1,2),\ (-2,-2,1,1,1,1),\ (-2,-2,2,-2,2,2), \end{gathered}$$

of the wall degrees 1 (the first seven), $\frac{3}{2}$ (the eighth, at $U = a$) and 2 (Theorem 39.21(i)).

The matrix. Input: the 3774 relations. Method: as in Exercise 55.5; the targets need 1023 relations, of rank 1023; 55 strengths on the first prime; three primes. Output: $\mathbf{B} \in \mathrm{Mat}_{15}(\mathbb{Q}(k))$ with 8 vanishing entries, numerators and denominators of degree at most 17 in lowest terms, and the common denominator

$$Q_c = (2k-5)(k-2)^2(k-3)^5(k-4)\,S_9(k),$$

S_9 irreducible of degree 9, $S_9 = 6555027k^9 - 143215495k^8 + \cdots - 6615463200$. Check: $\mathbf{B}$ agrees with eliminations of the whole box at four primes and strengths drawn at random. Receipt: `rayreader.py N "1 1 1 1 1 1 ; 1 1"`, read by `analyze_run.py`. $\mathbf{B}$ is regular at $k = \infty$, and

$$\det\big(\lambda - \mathbf{B}(\infty)\big) = (\lambda - 361)\,(\lambda - 25)^2\,(\lambda - 9)\,(\lambda - 1)^8\,(\lambda + 80)\,\big(\lambda^2 + \tfrac{34}{3}\lambda - \tfrac{361}{3}\big).$$

By Proposition 39.42(ii) the vectors β_η of the nondegenerate signs and β of the slice gauge are eigenvectors: computed exactly, $\mathbf{B}(\infty)\beta_\eta = K(\eta)^2\beta_\eta$ at the signs of native values $\frac{1}{361}$, $\frac{1}{25}$ (both orbits) and $\frac{1}{9}$, and $\mathbf{B}(\infty)\beta = -80\beta$ at $\big(\frac{-5-\sqrt{21}}{2}\big)$, five independent vectors (receipt `nsix_centre_exact.py`). The roots of $\lambda^2 + \frac{34}{3}\lambda - \frac{361}{3}$ are $\frac{-17\pm14\sqrt{7}}{3}$, the reciprocals of $\frac{17\pm14\sqrt{7}}{361}$, which are native values of gauges off the signs and the slice: the monodromy count of Exercise 55.5, run at this direction, reaches eighteen nondegenerate native gauges at each (receipt `critpoints.py`).

The law. The rows of Proposition 39.6 first depend at $h = 11$, and the relation $\sum_{j=0}^{11} c_j(k)\langle 1\rangle_{k+j} = 0$ has $c_j \in \mathbb{Z}[k]$ of degree 52 with coefficients of up to 88 digits, from ten primes; it holds at random points of four primes. By Proposition 39.6(ii) this relation, of order 11 with coprime coefficients, annihilates [1], so the values satisfy it; its order is at least the dimension of the cyclic submodule of [1], with equality when the spanning set is a set of masters (Definition 39.1). Factored over $\mathbb{Q}$,

$$c_0 = 3\,(2k+1)\,k^5(k+1)^2(k+2)^2(k+3)\,S_{41}(k),$$
$$c_{11} = -4691556000\,(k+4)(k+5)(k+6)(k+7)^2(k+8)^2(k+9)^2(k+10)^2\,S_{41}(k-1),$$

with S_{41} irreducible of degree 41, and the symbol is

$$\chi(\lambda) \propto (361\lambda-1)(25\lambda-1)(9\lambda-1)(\lambda-1)^5(80\lambda+1)(361\lambda^2-34\lambda-3),$$

whose roots are the native values found: $\frac{1}{361}, \frac{1}{25}, \frac{1}{9}$, the degenerate 1 five times, $-\frac{1}{80}$ and $\frac{17\pm14\sqrt{7}}{361}$. The eigenvalues of $\mathbf{B}(\infty)$ are the reciprocals of the roots of χ, with their multiplicities, and one more 25 and three more 1.

Line-up strengths. $q_{11}(k) = c_0(k-11)$ divides $\det \mathbf{W}(k)_J \prod_{j=0}^{10} Q_c(k-j)^{11-j}$ (Proposition 39.6(iii)). The irreducible factors of Q_c have degrees 1 and 9, so $S_{41}(k-11)$ divides $\det \mathbf{W}(k)_J$: 41 of the 52 degrees of c_0 are strengths at which the rows $w_0, \dots, w_{10}$ line up, and the other 11 are the rational roots $0, -\frac{1}{2}, -1, -2, -3$.

The low end and the closings. c_0 vanishes to order 5 at 0, and the low-end relation of Corollary 39.38(ii), $[k^5]c_0 \cdot 63 + \sum_{i=1}^{11} c_i(0)\langle 1\rangle_i = 0$, has integer coefficients of up to 69 digits after division by their greatest common divisor 11377315676160 (receipt `lowend_forms.py`). The closings $\mathsf{C}_j(1) = \mathrm{CT}(f^{-j})$ of Exercise 55.4 satisfy $\sum_{i=0}^{\min(11,j)} c_i(-j)\,\mathsf{C}_{j-i}(1) = 0$ exactly for $0 \le j \le 60$ (Corollary 39.36; receipt `nsix_ctcheck.py`).

The value. By Theorem 40.6, with $f^\star = \frac{1}{361}$ a simple root of χ, the density operator of order 52, the exponent $\frac{3}{2}$ at $f^\star$ (read from the law to 16 digits), and $g(0) = \big(2\Gamma(\frac{1}{2})^2 \cdot 361\big)^{5/2} \big/ \big(\Gamma(\frac{5}{2})\sqrt{\det H}\big)$: Beta sums from $K = 57$ and from $K = 82$ with 168 terms of the germ at 1188 bits, the law run back to $k = 1$. Output:

$$P_{\mathrm{N}_6}(\mathbf{1}; 1, 1) = \langle 1\rangle_1 = 4.57891247888240480638020373022855\ldots,$$

the two starts agreeing to 50 digits. Receipt: `rayreader.py N "1 1 1 1 1 1 ; 1 1" --digits 30`.

So the centre of N_6 has $V_1 = 63$, $f^\star = \frac{1}{361}$, a box accepted at $\mathfrak{B}_3(1,1)$ with fifteen spanning elements, the law of [1] of order 11 and degree 52, and $P_{\mathrm{N}_6}(\mathbf{1}; 1, 1) = 4.5789124788824048\ldots$, with $P/V_1 = 0.0726811\ldots$ □

Exercise 55.7 (The value span of N_6)**.** The *value span* of a ray is the $\mathbb{Q}$-span of its values $\langle 1\rangle_k$, $k \ge 1$. For the two rays of N_6 of Exercises 55.5 and 55.6:

(i) bound the value span by the law of [1] and the low-end relation;

(ii) find the integer relations of small height among 1 and the first values, read to 700 digits, by lattice reduction, and among them and the numbers $\ell = P_{\binom{[3]}{1}}(\mathbf{1}; 1, 1)$ and $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$.

Solution. (i) *The lean.* The leading coefficient of the law, $c_6 = 6998400\,(2k+1)(2k+3)(2k+5)(2k+7)(2k+9)(2k+11)(k+4)(k+5)^3\,r(k-1)$, has its rational roots at negative numbers, and

r, irreducible of degree 14, has none; so $c_6(k) \neq 0$ for every integer $k \geq 0$. The law holds at every $k \geq 1$ (Corollary 39.38(i)), so $\langle 1\rangle_{k+6} = -c_6(k)^{-1} \sum_{i<6} c_i(k) \langle 1\rangle_{k+i}$ for $k \geq 1$, and by induction every value lies in the $\mathbb{Q}$-span of $\langle 1\rangle_1, \ldots, \langle 1\rangle_6$. The low-end relation of Exercise 55.5(v) has the constant term $64402904777 \neq 0$ and the coefficient $3400346988339840000 \neq 0$ at $\langle 1\rangle_6$, so it puts 1 in the value span and $\langle 1\rangle_6$ in $\mathbb{Q} + \mathbb{Q}\langle 1\rangle_1 + \cdots + \mathbb{Q}\langle 1\rangle_5$. So the value span of the lean is

$$\mathbb{Q} + \mathbb{Q}\langle 1\rangle_1 + \mathbb{Q}\langle 1\rangle_2 + \cdots + \mathbb{Q}\langle 1\rangle_5,$$

of dimension at most 6. *The centre.* The same with $c_{11} = -4691556000\,(k+4)(k+5)(k+6)(k+7)^2(k+8)^2(k+9)^2(k+10)^2\,S_{41}(k-1)$, nonzero at every integer $k \geq 0$, and the low-end relation of Exercise 55.6, whose constant term and coefficient of $\langle 1\rangle_{11}$ are nonzero: the value span of the centre is $\mathbb{Q} + \mathbb{Q}\langle 1\rangle_1 + \cdots + \mathbb{Q}\langle 1\rangle_{10}$, of dimension at most 11.

(ii) *The values.* Input: the laws and the native gauges of the two rays. Method: Theorem 40.6 at 700 digits, the Beta sums from the strengths 861 and 886 with 2580 terms of the germ, at 20224 bits, and the laws run back; this gives $\langle 1\rangle_1, \ldots, \langle 1\rangle_7$ at the lean and $\langle 1\rangle_1, \ldots, \langle 1\rangle_{12}$ at the centre. Check: the two starting strengths agree to 700 digits; the low-end relations, which the reading does not use, hold on the values to 731 digits relative to their largest terms; and the values agree with those of Exercises 55.5 and 55.6. Receipt: `valuespan_N.py`.

The relations. Method: for numbers $v_0 = 1, v_1, \ldots, v_N$, the Lenstra–Lenstra–Lovász reduction of the lattice spanned by the rows $\big(\mathbf{e}_i,\ \lfloor 10^{660} v_i \rfloor\big)$; a reduced row $(x, *)$ with a small residual $\sum_i x_i v_i$ is a candidate integer relation, and the first rows that are not relations show the size of the generic vectors. Output at the lean, for $1, \langle 1\rangle_1, \ldots, \langle 1\rangle_6$: three vectors of heights $3.0 \cdot 10^9$, $5.2 \cdot 10^9$ and $1.4 \cdot 10^{10}$ with residuals below 10^{-724},

$$\begin{aligned}
&15476 - 3451\langle 1\rangle_1 + 556832\langle 1\rangle_2 - 17388081\langle 1\rangle_3 \\
&\qquad + 111849150\langle 1\rangle_4 - 425617416\langle 1\rangle_5 - 2986275600\langle 1\rangle_6, \\
&84581 - 18857\langle 1\rangle_1 + 3035312\langle 1\rangle_2 - 97811235\langle 1\rangle_3 \\
&\qquad + 798867930\langle 1\rangle_4 - 5212068120\langle 1\rangle_5 + 1459458000\langle 1\rangle_6, \\
&5489069 - 1222045\langle 1\rangle_1 + 190733734\langle 1\rangle_2 - 4628283534\langle 1\rangle_3 \\
&\qquad + 13506396540\langle 1\rangle_4 - 1721929104\langle 1\rangle_5 - 44906400\langle 1\rangle_6,
\end{aligned}$$

and then vectors of height $3 \cdot 10^{157}$ and residual 10^{-503}. Check: the low-end relation, which is exact, lies in the rational span of the three (exact linear algebra; receipt `valuespan_exact.py`). Solved for the last values, the three read

$$\langle 1\rangle_4 = \tfrac{556429709}{1602852300}\langle 1\rangle_3 - \tfrac{137833049}{9617113800}\langle 1\rangle_2 + \tfrac{26497699}{288513414000}\langle 1\rangle_1 - \tfrac{170029763}{412162020000},$$

and like expressions of $\langle 1\rangle_5$ and $\langle 1\rangle_6$ with denominators of up to 20 digits. Among $1, \langle 1\rangle_1, \langle 1\rangle_2, \langle 1\rangle_3$ and ℓ the reduction returns one vector of height $1.1 \cdot 10^7$ and residual 10^{-727}, the next of height 10^{163}:

$$3906\,\langle 1\rangle_1 - 506772\,\langle 1\rangle_2 + 10837800\,\langle 1\rangle_3 = 15263 + 1047\,\ell.$$

ℓ is the value of the minor $\binom{\{1,2,3,5\}}{2} = (\mathrm{N}_6/4) \setminus 6$ of N_6 at its own full lean $(\mathbf{1}; 0, 2)$ and at its centre: the procedure reads $\binom{[4]}{2}$ at both, with laws of order 2 and degrees 3 and 3, and returns ℓ to the 32 digits printed (Exercise 55.10).

At the centre, for $1, \langle 1\rangle_1, \ldots, \langle 1\rangle_{12}$, four vectors of heights $5.4 \cdot 10^{23}$ to $1.1 \cdot 10^{24}$ with residuals below 10^{-714}, the next of height $2.5 \cdot 10^{62}$ and residual 10^{-598}; the law read at $k = 1$ and the low-end relation, both exact, lie in their rational span, and they express $\langle 1\rangle_9, \ldots, \langle 1\rangle_{12}$

through $1, \langle 1\rangle_1, \dots, \langle 1\rangle_8$. Among $1, \langle 1\rangle_1, \dots, \langle 1\rangle_8$, ℓ and $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ the reduction returns two vectors, of heights $1.4 \cdot 10^{25}$ and $1.6 \cdot 10^{25}$ and residuals below 10^{-710}, the next of height $2.9 \cdot 10^{67}$; their two coefficients at ℓ and $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ form the nonsingular matrix $\begin{pmatrix} 146909488464924911235 & -115139161649314013904 \\ -10928078403398636616 & 24473573045860222080 \end{pmatrix}$, so they write ℓ and $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ through the values. Here $7(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ is the value of the minor $\binom{\{1,2,3,6\}}{1} = \mathrm{N}_6/\{4,5\}$ at its centre, and ℓ that of $\binom{\{1,2,3,5\}}{2}$.

So the value span of N_6 is $\mathbb{Q} + \sum_{i\le 5} \mathbb{Q}\langle 1\rangle_i$ at the lean and $\mathbb{Q} + \sum_{i\le 10} \mathbb{Q}\langle 1\rangle_i$ at the centre, of dimensions at most 6 and 11; the integer relations that lattice reduction finds at 700 digits, holding there to 724 and 714 digits, cut them to $\mathbb{Q} + \mathbb{Q}\langle 1\rangle_1 + \mathbb{Q}\langle 1\rangle_2 + \mathbb{Q}\langle 1\rangle_3$, containing ℓ, and to $\mathbb{Q} + \sum_{i\le 8} \mathbb{Q}\langle 1\rangle_i$, containing ℓ and $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$: at the lean the value of the minor $\binom{\{1,2,3,5\}}{2}$ at its own lean, at the centre the values of both minors on four marks at their centres, and besides them two numbers at the lean and six at the centre. □

Exercise 55.8 (V_8 at its full cobasis lean, read from its list)**.** Let V_8 be the list of rank four on $\mathcal{E} = \{1, \dots, 8\}$ with the pairs $P_1 = \{1,2\}$, $P_2 = \{3,4\}$, $P_3 = \{5,6\}$, $P_4 = \{7,8\}$, whose bases are the sixty-five sets of four marks other than the five unions $P_i \cup P_j$ with $\{i,j\} \neq \{3,4\}$. Read its ray with origin 0 and direction $(\mathbf{1}; 0, 2)$, of stride $f = \alpha^{\mathcal{E}}\Psi^{-2}$, by the procedure of Definition 41.8:

(i) the walls, V_1, the native gauge of the direction, $f^\star$ and $\det H$;

(ii) the box, its spanning set, the matrix $\mathbf{B}$ and its common denominator;

(iii) the relation of the rows and its line-up strengths;

(iv) the native gauges of the ray, and what they say about the dimension, the masters, the order of the law of [1] and $\mathbf{B}$ at infinite strength;

(v) the value $\langle 1\rangle_1 = P_{\mathrm{V}_8}(\mathbf{1}; 0, 2)$.

Solution. (i) *Walls and volume.* As for N_6 at its lean (Exercise 55.5(i)), $s = 0$, $t = 2$ and $d^*(S) = |S| - r(S)$ give $\kappa_{1,S} = 2r(S) - |S|$. Input: the 254 nonempty proper subsets of $\mathcal{E}$ and their ranks. Method: $\kappa_{1,S}$ for each, and the recursion over chains $F(U) = \kappa_{1,U}^{-1} \sum_{e\in U} F(U \setminus \{e\})$, $V_1 = \sum_e F(\mathcal{E} \setminus \{e\})$ of Exercise 55.5(i) (Proposition 39.34), in exact rationals. Output: the walls are 1 sixteen times, 2 sixty-one times, 3 one hundred and twelve times and 4 sixty-five times, all positive, and

$$V_1 = 300.$$

Check: the same program gives $V_1 = 66$ and 63 for the two rays of N_6, as computed by hand in Exercises 55.5 and 55.6. Receipt: `exact_data.py`.

The automorphisms. The non-bases are the unions of two pairs that involve P_1 or P_2, so an automorphism keeps $\{P_1, P_2\}$ and $\{P_3, P_4\}$; the 64 permutations that exchange the marks within pairs, P_1 with P_2 and P_3 with P_4 are automorphisms, and they keep the masses $\mathbf{1}$, so they are symmetries of the ray (Proposition 39.11(ii)).

The native gauge. The points fixed by the 64 automorphisms are, on the chart $\alpha_8 = 1$, the slice $\alpha = (x, x, x, x, 1, 1, 1, 1)$. A cobasis is the complement of a basis, so the cobases are the sets of four other than the complements $P_3 \cup P_4$, $P_2 \cup P_4$, $P_2 \cup P_3$, $P_1 \cup P_4$, $P_1 \cup P_3$ of the non-bases. On the slice a set C of four has $\alpha^C = x^{|C \cap (P_1 \cup P_2)|}$, the sets of four give $\sum_j \binom{4}{j}\binom{4}{4-j} x^j = 1 + 16x + 36x^2 + 16x^3 + x^4$, and the five sets left out give $1 + 4x^2$, so

$$\Psi = x\,(x^3 + 16x^2 + 32x + 16), \qquad f = \frac{x^4}{\Psi^2} = \frac{x^2}{(x^3 + 16x^2 + 32x + 16)^2},$$

$$\frac{d}{dx}\log f = \frac{-4\,(x^3+8x^2-8)}{x\,(x^3+16x^2+32x+16)}.$$

At a point fixed by the automorphisms the differential of $\log f$ in $y = \log\alpha$ is (u,u,u,u,v,v,v,v) with $u+v=0$, f being homogeneous of degree 0, and it vanishes when its derivative along the slice does, as in Exercise 55.5(ii). So the three roots of x^3+8x^2-8 give native gauges (Definition 38.4); at a root $x^3+16x^2+32x+16 = 8(x+1)(x+3)$, and the native value is

$$f = \Big(\frac{x}{8(x+1)(x+3)}\Big)^2.$$

The positive root $x^\star = 0.94566781799051109644\ldots$ gives $\alpha^\star$ (Theorem 38.14(i)) and

$$f^\star = 2.3709304548895617852\ldots\cdot 10^{-4};$$

the roots $-1.0748031540504515212\ldots$ and $-7.8708646639400595752\ldots$ give the native values $0.87033768220817625690\ldots$ and $8.6423132047649619559\ldots\cdot 10^{-4}$. The Hessian of $-\log f$ at $\log\alpha^\star$ on the chart is twice the covariances of the indicators under the cobasis law at $\alpha^\star$ (Theorem 38.15); reduced in $\mathbb{Q}(x^\star)$ (receipt `hessians.py`),

$$\det H = \frac{395719931704\,x^{\star 2} + 2812581517252\,x^\star - 3012741822955}{379727508532},$$

which is $0.0024055146373001934835\ldots$

(ii) *The box* (Procedure 41.8, the masters). Only Ψ is active. Input: the boxes $\mathfrak{B}_{\mathfrak{t}}(0,1)$ modulo the 64 automorphisms (Definition 39.15(iv), Definition 39.20(i)). Method: as in Exercise 55.5(iii). Output: $\mathfrak{B}_2(0,1)$ has 1155 orbits of stems, 4745 orbits of symbols and 10395 relations; at $\mathfrak{s}=1$ it leaves 36 free Laurent orbits of which 33 targets do not reduce to them, and at $\mathfrak{s}=0$ the target of 1 does not reduce: not accepted. $\mathfrak{B}_3(0,1)$ has 9723 orbits of stems, 32810 orbits of symbols and $87507 = 9723\cdot 9$ relations, the letter identities of the stems and their eight mark relations; one elimination leaves 60 free Laurent orbits of wall degree at most 2, every target reduces to them, and the box is accepted at $\mathfrak{s}=2$ (Theorem 39.21(i)), with a spanning set of 60 orbit averages. Receipt: `rayreader.py V "1 1 1 1 1 1 1 1 ; 0 2" --digits 30` (log `runlogs/V_lean.stdout`).

The matrix (the matrix over $\mathbb{Q}(k)$). Input: the 87507 relations. Method: the targets need 19581 of them, of rank 19581; eliminations modulo primes of 62 bits at random strengths; every entry read as a quotient of polynomials; Chinese remaindering with rational reconstruction. Output: on the first prime 178 strengths determine every entry, the largest sum of the degrees of a numerator and a denominator being 163; all the denominators divide one polynomial of degree 85, over which the numerators have degree at most 88, so each further prime needs 94 strengths; the entries become reconstructible over $\mathbb{Q}$ at seven primes, 432 bits. The common denominator is, up to a constant factor,

$$Q_c = k\,(k-1)^2(2k-3)(k-2)^8(2k-5)(k-3)^7\,S_{65}(k),$$

S_{65} irreducible of degree 65; 72 entries vanish, and in lowest terms the numerators have degree at most 83 and the denominators at most 80, so $d_{\mathbf{B}} = 83$. Check: $\mathbf{B}$ agrees with an elimination of the whole box at a prime and a strength drawn at random.

(iii) *The relation of the rows.* Input: $\mathbf{B}$. Method: the rows w_i of Proposition 39.6 modulo primes, their first dependence, reconstructed over $\mathbb{Q}$. Output (receipt as in (ii)): $w_0,\ldots,w_{23}$ are independent and w_{24} depends on them, so $h=24$, and the relation $\sum_{j=0}^{24} p_j(k)\langle 1\rangle_{k+j} = 0$ has $p_j \in \mathbb{Z}[k]$ of degree 377, with coefficients of up to 753 digits, from 63 primes, and over $\mathbb{Q}$

$$p_0 = k^7(k+1)^5(k+2)^5\prod_{j=3}^{7}(k+j)^3\prod_{j=8}^{13}(k+j)\,S_{339}(k),$$

S_{339} irreducible of degree 339, while p_{24} is a product of 38 linear factors, with roots at integers, halves and quarters from $-\frac{1}{2}$ to $-\frac{47}{2}$, and $S_{339}(k-1)$. Check: the relation holds at a prime and a point drawn at random. *Line-up strengths.* With $q_{24}(k) = p_0(k-24)$, Proposition 39.6(iii) gives

$$p_0(k-24) \;\Big|\; \det \mathbf{W}(k)_J \prod_{j=0}^{23} Q_c(k-j)^{24-j}$$

for every set J of 24 columns with $\det \mathbf{W}_J \neq 0$. The irreducible factors of Q_c have degree at most 65, so the irreducible $S_{339}(k-24)$ divides none of the $Q_c(k-j)$ and divides $\det \mathbf{W}(k)_J$: 339 of the 377 degrees of p_0 are strengths at which the rows $w_0, \dots, w_{23}$ line up, and the other 38 are the integers $0, \dots, -13$.

(iv) *The native gauges.* A native gauge of the ray is a point of X_F with $1 = 2R_e^*(\alpha)$ for every mark (Definition 38.4). Input: these equations, and the same with exponents $(\mathbf{a}; b)$ in place of $(\mathbf{1}; 2)$, $|\mathbf{a}| = 4b$, which are linear in the exponents. Method: as in Exercise 55.9(iii): Newton's method at random complex exponents, the solutions carried around random triangles of exponents until several turns in a row add nothing, run from two seeds; then every solution carried to $(\mathbf{1}; 2)$ along four routes, the straight segment and three broken ones through random exponents. Output: from both seeds, 839 solutions at random exponents, the count reaching 839 at the sixteenth and seventeenth turns and then staying there for four and six turns; at the direction, along every route, the same 331 nondegenerate native gauges, in 31 orbits of the 64 automorphisms, of sizes $1, 1, 1, 2, 2, 2, 2$, eight of 4, fourteen of 16 and two of 32, with 18 distinct native values:

one orbit:	$f^\star$, 0.000818456 (16), 0.000864231 (1), 0.124846403 (16), 0.870337682 (1), $-0.592832429 \pm 0.713227829\,i$ (16 each),
two orbits:	0.004487298 (4), -0.013533898 (8), -0.026238829 (8), 0.066968510 (32), $0.007758455 \pm 0.013607932\,i$ (32 each), 0.109146811 (32), $\frac{1}{8}$ (64), 0.870512702 (4),
three orbits:	0.021107646 (24), 0.416392354 (24),

the number of native gauges in brackets (renderings). The other 508 paths stop before the direction, at τ between 0.598 and $1 - 1.8 \cdot 10^{-6}$ along the segment, where the step collapses. Check: one native gauge of each orbit polished by Newton's method at 40 digits, with the Hessian determinants of modulus at least $\det H = 0.0024055\ldots$, reached at $\alpha^\star$; the three native gauges of the slice in (i) are the three orbits of size 1. Receipts: `critpoints.py` (`crit_V8_lean.json`, `crit_V8_lean_seed2.json`), `census_paths.py` (`census_V8_routes.json`), `escape_check.py` (`escape_V8.out`), `betas.py` (`betas_V8.out`).

So, by Theorem 38.6(iii), the ray has dimension at least 331; by Theorem 39.12(iii) the invariant module under the 64 automorphisms has dimension at least 31; and by Corollary 38.7 the law of [1] has order at least 18, so that with (iii) and Proposition 39.6(ii) it lies between 18 and 24. The vectors $\beta_c = (b_l(\alpha_c))_l$ of the spanning set at one native gauge of each orbit have rank 31, their singular values running from 1262 down to 0.036 (receipt `betas.py`): they do not span $\mathbb{C}^{60}$, and Proposition 39.42(i) does not decide whether the 60 are masters. At large strength the entries of $\mathbf{B}$ grow like k^3 (output, receipt as in (ii)): $\mathbf{B}$ is not regular at $k = \infty$, and Proposition 39.42(ii) does not apply to it.

(v) *The value* (Theorem 40.6). Input: the relation of (iii), $f^\star$ and $\det H$; $f^\star$ is a simple root of the symbol, and the exponent of the density at $f^\star$ is $\frac{n-3}{2} = \frac{5}{2}$. Method: as in Exercise 55.5(vi). Output (receipt as in (ii)):

$$P_{\mathrm{V}_8}(\mathbf{1}; 0, 2) = \langle 1 \rangle_1 = 7.12823937562968675472229135353893457156078898940720766490704\ldots,$$

two starting strengths agreeing to $2.4 \cdot 10^{-82}$, and $P/V_1 = 0.0237607979187656\ldots$ Check: the low-end relation of Corollary 39.38(ii), with $V_1 = 300$, holds on the values to 73 digits.

So V_8 at $(\mathbf{1}; 0, 2)$ has $V_1 = 300$, $f^\star = \big(x^\star/(8(x^\star+1)(x^\star+3))\big)^2$ with $x^{\star 3} + 8x^{\star 2} = 8$, a box accepted at $\mathfrak{B}_3(0,1)$ with 60 spanning elements, a relation of order 24 and degree 377 of which 339 degrees are line-up strengths, at least 331 native gauges in 31 orbits with 18 native values, and the value $7.1282839375629686754\ldots$ □

Exercise 55.9 (Sizing a reading: Q_6 and N_7)**.** Let Q_6 be the list of rank three on $\{1,\ldots,6\}$ whose bases are the seventeen triples other than $\{1,3,6\}$, $\{2,3,4\}$ and $\{2,5,6\}$, and N_7 the list of rank three on $\{1,\ldots,7\}$ whose bases are the thirty-four triples other than $\{1,2,5\}$. For the rays with origin 0 of Q_6 along $(1,3,2,3,1,2;2,2)$ and of N_7 along $(1,2,2,1,2,1,1;2,1)$, find what sizes their reading before any relation is written: the walls, V_1, the native gauge of the direction, the native gauges of the ray and their native values, with the bounds these give on the dimension of the ray and on the order of a law of [1]; then the size of the box with one unit of each letter at $\mathfrak{t} = 2$, and whether it is accepted.

Solution. (i) *Walls and volume* (Definition 8.1, Proposition 39.34). For Q_6, $s = t = 2$ and the masses add up to $12 = 2\cdot 3 + 2\cdot 3$, on the balance wall; the walls $\kappa_{1,S} = m_{1,S} - 2d(S) - 2d^*(S)$ of the 62 sets S are, by height and count,

$$1(4),\ 2(7),\ 3(13),\ 4(13),\ 5(12),\ 6(9),\ 7(3),\ 8(1),$$

all positive, and the recursion over chains of Exercise 55.5(i), run over the 62 sets (no automorphism of Q_6 fixes the masses), gives $V_1 = \frac{16493}{2430}$. For N_7, $s = 2$, $t = 1$ and $10 = 2\cdot 3 + 1\cdot 4$; the 126 walls are $1(7),\ 2(17),\ 3(29),\ 4(39),\ 5(29),\ 6(5)$, and $V_1 = \frac{3519}{128}$. The automorphisms of N_7 fixing the masses are the 12 permutations that exchange the marks 2 and 5 of the triple $\{1,2,5\}$ or not and permute the marks $4, 6, 7$ of mass 1. Receipt: `exact_data.py`.

(ii) *The native gauge of the direction* (Theorem 38.14(i)), by Newton's method on the chart: for Q_6, $\alpha^\star = (0.45796,\ 3.83890,\ 1.55835,\ 3.85580,\ 0.54507,\ 1)$, $f^\star = 8.3244647577707389\ldots \cdot 10^{-5}$ and $\det H = 0.13385450029314584\ldots$; for N_7, $\alpha^\star = (1.15660,\ 3.63195,\ 3.14019,\ 1,\ 3.63195,\ 1,\ 1)$, constant on the orbits of the automorphisms as it must be, $f^\star = 7.2002200376070769\ldots \cdot 10^{-5}$ and $\det H = 0.027073861743142843\ldots$ (renderings; receipt `hessians.py`).

(iii) *The native gauges.* A native gauge is a point of X_F at which $m_{1,e} = s\,R_e + t\,R_e^*$ for every mark (Definition 38.4). Input: these equations, and the same with the exponents $(\mathbf{a}; b_K, b_\Psi)$ in place of $(\mathbf{m}_1; s, t)$, $|\mathbf{a}| = 3b_K + (n-3)b_\Psi$, which are linear in the exponents. Method: for random exponents, a Groebner basis of the equations, multiplied by $K\Psi$, on the chart and saturated by the coordinates and the letters, modulo the prime 32003, and, separately, Newton's method at random complex exponents with the solutions carried around random triangles of exponents until several turns add nothing; then each solution carried along the segment to $(\mathbf{m}_1; s, t)$, a path that either arrives at a point of X_F or runs to its boundary; and a Groebner basis at $(\mathbf{m}_1; s, t)$ itself. Output: for Q_6, 114 solutions at random exponents by both methods; 90 of the paths arrive, at 90 distinct native gauges, all nondegenerate, with 90 distinct native values, and 24 run off; at the direction the Groebner basis has exactly 90 points counted with multiplicity, so these are all the native gauges. For N_7, 1174 solutions at random exponents; all 1174 arrive, at distinct nondegenerate native gauges, in 268 orbits of the 12 automorphisms (32 of size 1, 28 of size 2, 86 of size 3, 106 of size 6, 16 of size 12), with 83 distinct native values. Check: the native gauges of Q_6 polished at 40 digits, residuals below 10^{-37}, the Hessian determinants at least 0.13, the native values at least $1.6 \cdot 10^{-4}$ apart, and the same 90 values from two further runs with other random exponents. Receipts: `gb_count.py`, `gb_direction.py`, `critpoints.py`, `polish.py`.

So, by Theorem 38.6(iii), the dimension of the ray is at least 90 for Q_6 and at least 1174 for N_7; by Theorem 39.12(iii) the invariant module of N_7 under its 12 automorphisms has dimension at least 268; and by Corollary 38.7 every relation $\sum_j p_j(k) f^j \in \mathcal{L}$, the law of [1] among them, has order at least 90 for Q_6 and 83 for N_7, the number of distinct native values. These counts are read off the list and the direction alone.

(iv) *The box of* Q_6. Both letters are active, and the box with one unit of each is $\mathfrak{B}_2(1,1)$ (Definition 39.15(iv)). Input: the box, with no symmetry. Output: 361682 relations on 225874 symbols, the mark relations of 31785 stems and the letter identities, each of $1 + |\mathcal{B}| = 18$ terms (receipt `box_test.py Q6.json "1 3 2 3 1 2 ; 2 2" 2 1 1`). Method for the rest: the procedure, as in Exercise 55.5(iii) and (iv); receipt `rayreader.py Q6.json "1 3 2 3 1 2 ; 2 2" --digits 30`. Output: one elimination modulo a prime at a random strength leaves 114 free Laurent symbols of wall degree at most 1, and every target reduces to them, so the box is accepted at $\mathfrak{s} = 1$, and the spanning set of 114 spans a submodule that contains [1] (Theorem 39.21(i)). The targets need 78921 of the relations. Modulo the first prime **B** has a common denominator of degree 126 and numerators of degree up to 129, so it is not regular at $k = \infty$; it needs 271 strengths on that prime and 135 on each further one; and modulo that prime the rows first depend at $h = 90$, where 12288 consecutive strengths do not determine the relation, so that its degree exceeds 6100. By (iii) and Proposition 39.6(ii), $90 \le h \le 114$ whatever the spanning set, and the rows meet the lower bound.

The box of N_7. The box $\mathfrak{B}_2(1,1)$ modulo the 12 automorphisms has 71320 orbits of symbols, 7613 orbits of stems and 100719 relations of up to $1 + |\mathcal{B}| = 35$ terms. One elimination modulo $2^{61} - 1$ at a random strength has rank 63883; of the 359 Laurent orbits of wall degree at most 1, 247 are free, and their targets all lie in the box, but 246 of them do not reduce to the 247; at $\mathfrak{s} = 0$ the target of 1 does not reduce. So the box with one unit of each letter at $\mathfrak{t} = 2$ is not accepted (Definition 39.20(iii)), and Theorem 39.22 sends the search to larger boxes. By Definition 39.20(ii) the class of every invariant Laurent symbol of wall degree at most 1 is a combination of the 247 free ones, fewer than the 268 dimensions of the invariant module found in (iii). Receipt: `box_test.py N7.json "1 2 2 1 2 1 1 ; 2 1" 2 1 1`. The next boxes of the search are larger: $\mathfrak{B}_2(2,1)$ has 236600 relations on 158724 symbols, and $\mathfrak{B}_3(1,1)$ has 707989 relations of up to 35 terms (receipt for the search, `rayreader.py N7.json "1 2 2 1 2 1 1 ; 2 1" --digits 30`).

So before any relation is written, the walls give $V_1 = \frac{16493}{2430}$ and $\frac{3519}{128}$, and the critical equations give at least 90 and 1174 dimensions and laws of order at least 90 and 83; the box of Q_6 at $\mathfrak{t} = 2$ is accepted with 114 spanning elements, and the box of N_7 with one unit of each letter at $\mathfrak{t} = 2$ is not accepted. □

Exercise 55.10 (A table of rays read by the procedure)**.** Let $\binom{[n]}{1}$ be the list of rank one on $\{1, \dots, n\}$ whose bases are the single marks, $\binom{[n]}{2}$ the list of rank two whose bases are all the pairs, H_4 the list of rank two on $\{1,2,3,4\}$ whose bases are the five pairs other than $\{1,2\}$, and W_3 the wheel with three spokes (Proposition 39.65), of rank three on its six spokes and rims, whose bases are the sixteen spanning trees of its graph. Read by the procedure of Definition 41.8 the rays with origin 0 of

$$\tbinom{[3]}{1},\ \tbinom{[4]}{1},\ \tbinom{[5]}{1},\ \tbinom{[4]}{2},\ \tbinom{[5]}{2},\ \mathrm{H}_4,\ \mathrm{N}_6 \text{ along } (\mathbf{1}; 1, 1); \qquad \tbinom{[4]}{2},\ W_3,\ \mathrm{N}_6,\ \mathrm{V}_8 \text{ along } (\mathbf{1}; 0, 2);$$
$$\tbinom{[3]}{1} \text{ along } (2\mathbf{1}; 4, 1); \qquad \mathrm{H}_4 \text{ along } (1, 1, 3, 3; 3, 1),$$

N_6 and V_8 as in Exercises 55.4 and 55.8, and the ray of $\binom{[3]}{1}$ with origin $(u_0; 0, 0)$, $u_0 = (-\frac{1}{2}, 0, \frac{1}{2})$, and direction $(\mathbf{1}; 1, 1)$, whose value at $k = 1$ is $P_{\binom{[3]}{1}}(\frac{1}{2}, 1, \frac{3}{2}; 1, 1)$. For each ray give:

(i) the accepted box with its stems, symbols and relations modulo the symmetries of the ray, the bound $\mathfrak{s}$ at which it is accepted, the size $\mathfrak{m}$ of its spanning set, the largest degree $d_{\mathbf{B}}$ of

a numerator or a denominator of an entry of $\mathbf{B}$ in lowest terms, and the order h and the degree D of the relation of the rows;

(ii) whether the spanning set is a set of masters and that relation the law of [1], and the spectrum of $\mathbf{B}(\infty)$ where $\mathbf{B}$ is regular at $k = \infty$;

(iii) V_1 and the value $\langle 1 \rangle_1$, with the checks that the reading allows.

Solution. (i) *The boxes, the matrices and the rows.* Input: the list and the direction. Method: the procedure as in Exercise 55.5(iii) and (iv). The boxes $\mathfrak{B}_\mathfrak{t}$ with one unit of each active letter are tried for $\mathfrak{t} = 2, 3, \ldots$ (Definition 39.15(iv), Theorem 39.22), each reduced modulo the symmetries of the ray: the automorphisms that fix the masses and the origin, and the Cremona at a centre with origin 0 (Proposition 39.11, Definition 39.20(i)). One elimination modulo a prime of 61 bits at a random strength decides acceptance (Definition 39.20(iii)); $\mathbf{B}$ over $\mathbb{Q}(k)$ comes from eliminations of the relations that the targets need, modulo primes of 62 bits at random strengths, with rational reconstruction; and the rows w_i of Proposition 39.6 give the first dependence, reconstructed over $\mathbb{Q}$ from several primes. Output:

ray	box	stems	symbols	relations	$\mathfrak{s}$	$\mathfrak{m}$	$d_\mathbf{B}$	(h, D)
$\binom{[3]}{1}$, $(\mathbf{1}; 1, 1)$	$\mathfrak{B}_2(1,1)$	4	30	32	1	2	2	$(2, 2)$
$\binom{[4]}{1}$, $(\mathbf{1}; 1, 1)$	$\mathfrak{B}_2(1,1)$	5	42	46	1	2	3	$(2, 3)$
$\binom{[5]}{1}$, $(\mathbf{1}; 1, 1)$	$\mathfrak{B}_3(1,1)$	10	100	112	2	3	5	$(3, 4)$
$\binom{[3]}{1}$, $(2\mathbf{1}; 4, 1)$	$\mathfrak{B}_2(1,1)$	17	79	124	1	2	4	$(2, 6)$
$\binom{[3]}{1}$, $(\mathbf{1}; 1, 1)$, u_0	$\mathfrak{B}_2(1,1)$	19	110	149	1	4	3	$(3, 4)$
$\binom{[4]}{2}$, $(\mathbf{1}; 0, 2)$	$\mathfrak{B}_2(0,1)$	8	20	40	1	2	4	$(2, 3)$
$\binom{[4]}{2}$, $(\mathbf{1}; 1, 1)$	$\mathfrak{B}_2(1,1)$	7	33	66	1	2	4	$(2, 3)$
$\binom{[5]}{2}$, $(\mathbf{1}; 1, 1)$	$\mathfrak{B}_3(1,1)$	21	234	245	2	5	8	$(4, 6)$
H_4, $(\mathbf{1}; 1, 1)$	$\mathfrak{B}_2(1,1)$	17	102	180	1	4	3	$(4, 7)$
H_4, $(1, 1, 3, 3; 3, 1)$	$\mathfrak{B}_2(1,1)$	115	631	1000	1	4	9	$(4, 25)$
W_3, $(\mathbf{1}; 0, 2)$	$\mathfrak{B}_2(0,1)$	66	211	462	1	2	8	$(2, 5)$
N_6, $(\mathbf{1}; 0, 2)$	$\mathfrak{B}_2(0,1)$	104	329	728	1	7	6	$(6, 24)$
N_6, $(\mathbf{1}; 1, 1)$	$\mathfrak{B}_3(1,1)$	252	1909	3774	2	15	17	$(11, 52)$
V_8, $(\mathbf{1}; 0, 2)$	$\mathfrak{B}_3(0,1)$	9723	32810	87507	2	60	83	$(24, 377)$

At the centres of $\binom{[5]}{1}$, $\binom{[5]}{2}$ and N_6 the box $\mathfrak{B}_2(1,1)$ is not accepted: at $\mathfrak{s} = 1$ it leaves 2, 3 and 8 free Laurent orbits of which 1, 2 and 7 targets do not reduce to them, and at $\mathfrak{s} = 0$ the target of 1 does not reduce; at the lean of V_8, $\mathfrak{B}_2(0,1)$ leaves 36 free orbits at $\mathfrak{s} = 1$, of which 33 targets do not reduce, and fails at $\mathfrak{s} = 0$ the same way. Every other box in the table is the first one tried. Check: every $\mathbf{B}$ agrees with an elimination of the whole box at a prime and a strength drawn at random, and every relation of the rows holds at a random prime and point; on the thirteen rays other than V_8 both checks are repeated at three fresh primes and points. Receipts: `runs_table.sh`, `table_summary.py`, `tests/check_run.py` (`table_checkrun.out`).

(ii) *Masters and the law of* [1]. By Proposition 39.6(ii), with Theorem 39.21(iii), h is at least the dimension of the cyclic submodule of [1], with equality when the spanning set is a set of masters, and then the relation of the rows is the law of [1]; by Corollary 38.7 that dimension is at least the number of distinct native values of nondegenerate native gauges. So the relation is the law of [1] as soon as either the vectors $\beta_c = (b_l(\alpha_c))_l$ at nondegenerate native gauges span $\mathbb{C}^\mathfrak{m}$ (Proposition 39.42(i)), or h distinct native values are found; in the second case, when moreover $h = \mathfrak{m}$, the cyclic submodule of [1] fills the span of the $\mathfrak{m}$ classes, and the spanning set is a set of masters. Input: the critical equations of each direction. Method: the census of Exercise 55.9(iii),

monodromy at random exponents and paths to the direction; each native gauge polished at 40 digits with its Hessian; and the vectors β_c at one native gauge of each orbit, each b_l averaged over the symmetries of the ray. Output and conclusion:

- $\binom{[3]}{1}$, $\binom{[4]}{1}$ at their centres: the table's gauge, of native value $\frac{1}{9}$ and $\frac{1}{16}$, and the signs with one scale -1, of native value 1 and $\frac{1}{4}$ (Theorem 38.17(ii)), 4 and 5 native gauges in all, every one nondegenerate; the two vectors β_c are independent: masters, and the law of [1].
- $\binom{[3]}{1}$ along $(\mathbf{21};4,1)$: 4 native gauges, of native values $\frac{1}{243}$ and $-\frac{27}{64}$, two independent vectors: masters. The ray with origin u_0: the 4 native gauges of the centre direction, which no symmetry of the ray permutes, give four independent vectors: masters.
- $\binom{[5]}{2}$ at its centre: 66 native gauges in 6 orbits of the 120 automorphisms, of native values $\frac{1}{100}, \frac{1}{4}, -\frac{1}{8}, 1$, all nondegenerate, with vectors of rank 5: masters, and $h = 4 < \mathfrak{m}$, the cyclic submodule of [1] of dimension 4 inside $\mathfrak{N}$ of dimension 5 (Exercise 54.20).
- $\binom{[5]}{1}$ at its centre: 16 native gauges, the table's gauge ($\frac{1}{25}$), the five signs with one scale -1 ($\frac{1}{9}$) and the ten with two (1); three distinct native values and $h = \mathfrak{m} = 3$: masters and the law of [1], although the three vectors β_c lie in a plane. $\binom{[4]}{2}$ at both directions: 4 native gauges, of native values $\frac{1}{36}$ (the table's gauge) and $\frac{1}{4}$ (an orbit of three), with $h = \mathfrak{m} = 2$, and W_3 at $(\mathbf{1};0,2)$: 3 native gauges, of native values $\frac{1}{256}$ and $\frac{1}{4}$, with $h = \mathfrak{m} = 2$: masters and the law of [1], the two vectors β_c being proportional.
- N_6: Exercises 55.5 and 55.6. V_8: Exercise 55.8.
- H_4: of the 6 critical points at random exponents, two arrive at nondegenerate native gauges at each direction. At the centre they are the table's gauge and the sign $(-1,-1,1,1)$, of native values $\frac{1}{25}$ and $\frac{1}{9}$ and Hessian determinants $-\frac{32}{625}$ and $\frac{32}{81}$ on the chart; along $(1,1,3,3;3,1)$ they are the points $(x,x,1,1)$ with $3x^2+8x-1=0$, of native values $\frac{7643\pm1064\sqrt{19}}{1366875}$, the larger one, at $x=\frac{\sqrt{19}-4}{3}>0$, being $f^\star$. The other four paths meet in pairs at the points $(\mp i,\pm i,-1,1)$ at the centre and $(\mp\frac{i}{\sqrt{3}},\pm\frac{i}{\sqrt{3}},-1,1)$ along $(1,1,3,3;3,1)$, native gauges of native value 1 whose Hessian is singular (exact; receipt `h4_gauges.py`). So Corollary 38.7 bounds the dimension of the cyclic submodule of [1] below by 2 only, and the two vectors β_c span a plane: the relation of the rows is a relation of order 4 in $\mathcal{L}$, of order at least that of the law of [1] (Theorem 39.21(iii)), which lies between 2 and 4.

Infinite strength. $\mathbf{B}$ is regular at $k=\infty$ on nine of the rays, with the spectra in the table of (iii), and at every nondegenerate native gauge of the census β_c is an eigenvector of $\mathbf{B}(\infty)$ for $f(\alpha_c)^{-1}$, to 10^{-38} at 40 digits (Proposition 39.42(ii)). On $\binom{[5]}{1}$, $\binom{[4]}{2}$ and W_3 some entries of $\mathbf{B}$ have numerators of larger degree than their denominators, and Proposition 39.42(ii) says why they must: nondegenerate native gauges of distinct native values have dependent vectors β_c there, three in a plane for $\binom{[5]}{1}$ and two on a line for the others, which a regular $\mathbf{B}$ would make independent eigenvectors. For V_8 see Exercise 55.8.

(iii) *The values.* V_1 is computed from the walls by Proposition 39.34 with the recursion over chains of Exercise 55.5(i) (receipt `exact_data.py`); for the ray with origin u_0 it is that of the direction $(\mathbf{1};1,1)$. The values come from Theorem 40.6. Input: the relation of the rows, $f^\star$ and $\det H$. Method: as in Exercise 55.5(vi), asked to 60 digits. Output:

Check: on every ray the two starting strengths agree to at least 82 digits. On the thirteen rays with origin 0 the low-end relation of Corollary 39.38(ii), $[k^{n-1}]p_0\cdot V_1+\sum_{i=1}^{h}p_i(0)\langle 1\rangle_i=0$, which the reading does not use and which holds for the relation of the rows as well as for the law of [1], holds on the values $\langle 1\rangle_1,\dots,\langle 1\rangle_h$ to at least 89 digits relative to its largest term on the twelve read here at 60 digits, and to 73 digits on V_8 (Exercise 55.8(v)). Five values agree with numbers computed otherwise: those of $\binom{[3]}{1}$ at its centre and of $\binom{[4]}{2}$ at both directions with $\frac{1}{3}\big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\frac{1}{3}+\mathbb{Z}})((0,\infty))-(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\frac{2}{3}+\mathbb{Z}})((0,\infty))\big)$, summed as the series of Definition 5.2, to 90 digits; those of $\binom{[4]}{1}$ at its centre and of W_3 at $(\mathbf{1};0,2)$ with $7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ and $6\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$, to 89 digits; and that of the ray with origin u_0 with

$$\int_0^\infty 2\log\frac{(1+u^2)^2}{u^2}\,\frac{du}{1+u^2+u^4},$$

computed by quadrature at 90 digits, to 84 digits. Receipts: `table_check.py` (`table_check.out`), `table_masters.py` (`table_masters.out`).

So the procedure reads every ray of the table from its list and its direction, with boxes of up to 87507 relations; the relation of the rows is the law of [1] on all of them but the two rays of H_4 and V_8, where the census bounds the law's order below by 2 and 18; every value passes the low-end relation, and the five that can be compared with numbers computed otherwise agree with them to 84 digits or more. In particular $\binom{[4]}{2}$ has the value ℓ of $\binom{[3]}{1}$ at its centre both at $(\mathbf{1};0,2)$ and at $(\mathbf{1};1,1)$, to 90 digits. □

55.4 Triangles of classes

In this section $\Delta(s_0,s_1,s_2)$, $s_i\ge 1$, is the list $\binom{[3]}{2}$ with its mark h_i replaced by a parallel class C_i of s_i marks (Definition 21.1); its bases are the pairs of marks in different classes. With the totals $A_i=\sum_{e\in C_i}\alpha_e$ and $A_i'=\sum_{e\in C_i}\alpha_e^{-1}$,

$$K(\alpha)=A_0A_1+A_0A_2+A_1A_2=e_2(A),\qquad K(\alpha^{-1})=e_2(A'),\qquad f^{-1}=e_2(A)\,e_2(A'),$$

on the centre ray at the strength one. $\Sigma(s)=\{s,s-2,\dots,-s\}$ is the set of the sign values of a class of s marks. The lists H_4, R_5 and T_5 read in this chapter are $\Delta(2,1,1)$, $\Delta(2,2,1)$ and

$\Delta(3,1,1)$, and $\mathrm{J}_6 = \Delta(3,2,1)$. Values of f^{-1} are written as integers, so that the roots of a symbol, the native values, are their reciprocals. The receipts are in the folder `triangles/` of the receipts of this version.

Exercise 55.11 (Native and corner values of a triangle of classes)**.** For $\Delta(s_0,s_1,s_2)$:

(i) find the native gauges of the centre ray and their native values;

(ii) find the corner values of every class of at least two marks (Definition 38.24);

(iii) show that the corners add to the native values exactly the values $(a_j a_k)^{-2}$ with $a_j \in \Sigma(s_j)$, $a_k \in \Sigma(s_k)$ nonzero, $\{i,j,k\} = \{0,1,2\}$, for a class C_i of odd size $s_i \geq 3$;

(iv) list them for J_6.

Solution. (i) Native gauges. The core is $\mathcal{H} = \binom{[3]}{2}$ with $K_{\mathcal{H}}(x) = e_2(x)$ and $K_{\mathcal{H}/h_i} = x_j + x_k$. By Theorem 42.24(b) each class is occupied, $\alpha_e = \eta_e \tau_i$ on C_i with a sign value $a_i \in \Sigma(s_i)$, or empty, $A_j + A_k = A'_j + A'_k = 0$.

All classes occupied, every $a_i \neq 0$. The core reads the weighted triangle $K^{(a)}(\tau) = e_2(p)$ with $p_i = a_i\tau_i$, and $K^{(a)}(\tau^{-1}) = e_2(q)$ with $q_i = a_i\tau_i^{-1}$. Its occupations are $R_i(\tau) = 1 - p_j p_k/e_2(p)$ and $R_i(\tau^{-1}) = 1 - q_j q_k/e_2(q)$, so the native-gauge equations of the weighted core read $p_j p_k/(q_j q_k) = e_2(p)/e_2(q)$ for the three pairs, that is $\tau_j^2\tau_k^2 = e_2(p)/e_2(q)$; hence $\tau_0^2 = \tau_1^2 = \tau_2^2$, a sign up to the scale, and at a sign the equation holds. So these native gauges are the signs η of the list with $K(\eta) = e_2(a) \neq 0$, of the values $f^{-1} = e_2(a)^2$ (Theorem 38.17).

One occupied class of the sign value $a_i = 0$, possible for even s_i. The weighted core is the monomial $a_j a_k \tau_j \tau_k$, so $f^{-1} = (a_j a_k)^2 = e_2(a)^2$; the equations of C_j and C_k hold identically, the occupations of a monomial being constant, and the equation of C_i in Theorem 42.24(b) reads $\varsigma_i(\alpha)\tau_i^2 = \varsigma_i(\alpha^{-1})$ with $\varsigma_i = (A_j + A_k)/(A_j A_k)$, that is

$$\tau_i^2 = \tau_j\tau_k \, \frac{a_k\tau_j + a_j\tau_k}{a_j\tau_j + a_k\tau_k} :$$

these native gauges form curves, of the value $e_2(a)^2$ with $a_i = 0$. For $a_j = a_k = 1$ and a pair this is the curve $\{A = 0,\ \alpha_a^2 = \alpha_2\alpha_3\}$ of H_4 (Exercise 55.1).

One empty class C_i. Then $A_k = -A_j$ and $A'_k = -A'_j$; with C_j, C_k occupied, $a_j\tau_j = -a_k\tau_k$ and $a_j/\tau_j = -a_k/\tau_k$, so $a_j^2 = a_k^2$, and $K = A_jA_k$, $f^{-1} = (A_jA'_j)(A_kA'_k) = a_j^4 = e_2(a_i, a_j, -a_j)^2$ for any a_i: a value already in the first list.

Two empty classes C_i, C_j. Then $A_i = A_j = -A_k$ and $A'_i = A'_j = -A'_k$, so $K = -A_k^2$ and $f^{-1} = (A_kA'_k)^2 = a_k^4$, with the equation of C_k satisfied, its occupation being $A_k(A_i+A_j)/e_2(A) = 2$ on both sides. An empty class takes the prescribed totals, of the product $A_iA'_i = a_k^2$: a class of at least two marks always can, and a single mark, which has $A_iA'_i = 1$, only when $a_k = \pm 1$. These are the values a_k^4 of two empty classes around C_k.

Three empty classes force $A_0 = A_1 = A_2 = 0$, so $K = 0$, outside X_F.

So the native values of f^{-1} are the $e_2(a)^2$, $a \in \Sigma(s_0) \times \Sigma(s_1) \times \Sigma(s_2)$, $e_2(a) \neq 0$, at signs or, when some $a_i = 0$, on curves, together with the values a_k^4 of two empty classes around an occupied class C_k, an empty single mark requiring $a_k = \pm 1$.

(ii) Corner values. The class C_i, $s_i \geq 2$, sits at the marker h_i of the list $\mathcal{H}' = \binom{[3]}{2}\langle C_j, C_k\rangle$ on $C_j \sqcup C_k \sqcup \{h_i\}$, and by Corollary 38.28 its corner values are $N(\mathcal{H}' \setminus h_i \,|\, \mathcal{H}'/h_i)$, at the corner of Ψ. Here $\mathcal{H}' \setminus h_i$ has $K = A_jA_k$ and $\mathcal{H}'/h_i$ has $K = A_j + A_k$. On the torus of $C_j \sqcup C_k$ modulo the scale the coordinates are the shapes of the two classes and their relative scale; $f^{-1}_{\mathcal{H}'\setminus h_i} = (A_jA'_j)(A_kA'_k)$ does not depend on the relative scale, and the zero set of $A_j + A_k$ fixes it, a smooth hypersurface

where $A_j \neq 0$. So the native gauges of $\mathcal{H}' \setminus h_i$ on $\mathcal{H}'/h_i$ are the points at which both $A_jA'_j$ and $A_kA'_k$ are critical on the shapes of their classes, the signs of each class with nonzero totals (Lemma 42.27), and the corner values of f^{-1} are the $(a_ja_k)^2$ with $a_j, a_k \neq 0$. The points of the third kind of Proposition 38.26(iii) give no finite value: the room factor A_jA_k is singular only where $A_j = A_k = 0$, where $f^{-1}_{\mathcal{H}'/h_i} = (A_j + A_k)(A'_j + A'_k)$ vanishes.

(iii) $(a_ja_k)^2 = e_2(a)^2$ with $a_i = 0$. For even s_i, $0 \in \Sigma(s_i)$, and these values are native values, on the curves of (i). For odd s_i, $0 \notin \Sigma(s_i)$, and the value $(a_ja_k)^2$ is a native value only when it equals some $e_2(a')^2$ or some a'^4_k; the corners add the others. A class of one mark has no corner.

(iv) J_6. $\Sigma(3) = \{\pm 3, \pm 1\}$, $\Sigma(2) = \{\pm 2, 0\}$, $\Sigma(1) = \{\pm 1\}$. Up to the global sign take $a_2 = 1$:

a_0	a_1	$e_2(a)$	a_0	a_1	$e_2(a)$	a_0	a_1	$e_2(a)$
3	2	11	1	2	5	−1	−2	−1
3	0	3	1	0	1	−3	2	−7
3	−2	−5	1	−2	−3	−3	0	−3
−1	2	−1	−1	0	−1	−3	−2	1

So the native values of f^{-1} are $121, 49, 25, 9, 1$, the values 9 and 1 also on the curves $a_1 = 0$; two empty classes give only 1, around the mark or around the triple at $a_0 = \pm 1$, the pair not being able to sit around an empty mark since $a_1^2 = 4 \neq 1$. The corner values are $(a_1a_2)^2 = 4$ for the triple and $(a_0a_2)^2 \in \{9, 1\}$ for the pair. The corner value 4 of the triple is not a native value. □

Exercise 55.12 (The weight-zero curve of a pair)**.** In $\Delta(s_0, s_1, s_2)$ let C_i be a pair, and $a_j \in \Sigma(s_j)$, $a_k \in \Sigma(s_k)$ nonzero with $a_j^2 \neq a_k^2$. Normalize the scale of C_j to 1, and write r for the scale of C_k and τ for that of the pair.

(i) Show that the native gauges with C_i at a sign of total zero and C_j, C_k at signs of the totals a_j, a_k form one curve Γ for the two sign patterns $(a_j, 0, \pm a_k)$, and that its quotient by the exchange of the two marks of the pair is a sphere less four points.

(ii) Find where Γ leaves the torus.

(iii) Show that one blow-up makes the stride regular at the corner of Ψ of the pair, and that the corner is a point of the closure of Γ.

Solution. (i) By Exercise 55.11(i), with $a_i = 0$, $f^{-1} = (A_jA'_j)(A_kA'_k) = (a_ja_k)^2$ and the equation of C_i is

$$\Gamma: \qquad \tau^2 = r\,\frac{a_k + a_jr}{a_j + a_kr}.$$

The point of C_k is r times a sign pattern of the total a_k, which is $-r$ times one of the total $-a_k$; so the patterns $(a_j, 0, a_k)$ and $(a_j, 0, -a_k)$ give one curve, under $r \mapsto -r$. The exchange of the two marks of the pair is $\tau \mapsto -\tau$, and $\Gamma \to \mathbb{P}^1_r$ is two to one, branched where τ^2 is 0 or ∞: τ^2 has simple zeros at $r = 0$ and $r = -a_k/a_j$ and simple poles at $r = -a_j/a_k$ and $r = \infty$, four distinct points since $a_j^2 \neq a_k^2$. So

$$\Gamma/S_2 \cong \mathbb{P}^1_r \setminus \{0,\ \infty,\ -a_k/a_j,\ -a_j/a_k\}, \qquad \chi(\Gamma/S_2) = 2 - 4 = -2.$$

(ii) With $A_j = a_j$, $A'_j = a_j$, $A_k = a_kr$ and $A'_k = a_k/r$: as $r \to -a_k/a_j$, $\tau \to 0$ and $e = A'_j + A'_k = a_j + a_k/r \to 0$, so Γ runs into the corner of Ψ of the pair (Corollary 38.28); as $r \to -a_j/a_k$, $\tau \to \infty$ and $A_j + A_k \to 0$, the image of that corner under the Cremona, the corner of K at the wall of $C_j \cup C_k$; as $r \to 0$, $\tau \sim (a_kr/a_j)^{1/2}$, so C_k and C_i shrink at the rates r and $r^{1/2}$, a flag of length two, $C_k \subsetneq C_k \cup C_i$, and $r \to \infty$ is its image. At that flag the step factors $\sum_{C_i} u$ of K and $\sum_{C_i} u^{-1}$

of Ψ vanish together on the step C_i, the pair being at a sign of total zero, as Proposition 38.30(i) requires.

(iii) Near the corner of Ψ put $\rho = \tau$, let $b = \sum_{C_i} u^{-1}$ in the normalized shape of the pair and x the ratio of its two scales, so that $\sum_{C_i} u = xb$; with $S = A_j + A_k$, $P = A_j A_k$, $P' = A'_j A'_k$, $S' = A'_j + A'_k = e$ and $\hat{e} = e/\rho$. From $K = A_i S + P$, $A_i = \rho\, xb$ and $A'_i = \rho^{-1} b$,

$$f^{-1} = xb^2 SS' + \rho\, xbSP' + \rho^{-1} bS'P + PP' = PP' + b\left(\hat{e}P + \rho\, xSP'\right) + \rho\, xS\hat{e}\, b^2,$$

and $d\rho/\rho \wedge de = d\rho \wedge d\hat{e}$. So in the chart $(\rho, \hat{e})$ of the blow-up of $\{\rho = e = 0\}$ the stride and the origin form are regular at the corner. $PP' = (A_j A'_j)(A_k A'_k)$ does not depend on the relative scale of C_j and C_k; at $b = 0$ the only condition left is $\partial_b f^{-1} = \hat{e}P + \rho\, xSP' = 0$, whose $\hat{e}$-derivative is $P \neq 0$. So the critical locus near the corner is the smooth curve $\{b = 0,\ \hat{e}P + \rho x SP' = 0\}$ at the signs of C_j and C_k, which crosses the exceptional divisor $\rho = 0$, with $f^{-1} = (a_j a_k)^2$ on it: the corner is a point of the closure of Γ, a puncture of the curve, and not a source of its own. □

Exercise 55.13 (The class of three and of four marks at silence)**.** For $s = 3$ and $s = 4$ write the operator $\widetilde{A}_s$ of Theorem 42.28, check it on the closings, and read its exponents at 0, at the sign values and at ∞, and the Jordan types of the monodromy at 0.

Solution. $s = 3$. The operators of Theorem 42.12(i) for $n = 3$ are $\mathbf{R}_2 = \vartheta^2 - 3y$, $\mathbf{R}_3 = \vartheta \mathbf{R}_2 - 4y\mathbf{R}_1 = \vartheta^3 - 7y\vartheta - 3y$ and

$$\mathbf{Q}_3 = \mathbf{R}_4 = \vartheta \mathbf{R}_3 - 3y\mathbf{R}_2 = \vartheta^4 - y\,(10\vartheta^2 + 10\vartheta + 3) + 9y^2,$$

using $\vartheta y = y(\vartheta + 1)$; so $q_{3,0} = \vartheta^4$, $q_{3,1} = -(10\vartheta^2 + 10\vartheta + 3)$, $q_{3,2} = 9$, and $\xi^4 - 10\eta\xi^2 + 9\eta^2 = (\xi^2 - 9\eta)(\xi^2 - \eta)$. Then $c_{3,0}(x) = x^2$, $c_{3,1}(x) = q_{3,1}(-x - 1) = -(10x^2 + 10x + 3)$ and $c_{3,2}(x) = q_{3,2}(-x - 2)(x + 1)^2 = 9(x + 1)^2$. The closings $\mathsf{C}_j = \sum_{a+b+c=j} \binom{j}{a,b,c}^2 = 1, 3, 15, 93, \dots$ satisfy $\sum_k c_{3,k}(-j)\mathsf{C}_{j-k} = 0$:

$$j^2\, \mathsf{C}_j - (10j^2 - 10j + 3)\, \mathsf{C}_{j-1} + 9(j-1)^2\, \mathsf{C}_{j-2} = 0,$$

at $j = 2$: $4 \cdot 15 - 23 \cdot 3 + 9 \cdot 1 = 0$; at $j = 3$: $9 \cdot 93 - 63 \cdot 15 + 36 \cdot 3 = 0$. The operator is

$$\widetilde{A}_3 = (\theta + 1)^2 - \big(10(\theta + 1)^2 + 10(\theta + 1) + 3\big)t^{-1} + 9(\theta + 2)^2 t^{-2}, \qquad \theta = t\partial_t,$$

of order 2, with the leading coefficient $t^2(1 - 10t^{-1} + 9t^{-2}) = (t - 1)(t - 9)$: the sign values 1 and 9. At 0, $t^2\widetilde{A}_3 = t^2(\theta + 1)^2 - t\big(10\theta^2 + 10\theta + 3\big) + 9\theta^2$, whose indicial polynomial $9\theta^2$ gives the exponents $0, 0$, the list $0, \dots, h - 2$ of Theorem 42.28(iv) with $h = 2$, each twice. At ∞ the indicial polynomial is $(1 - \theta_w)^2$ in $w = 1/t$: the exponents $1, 1$. At a sign value they are 0 and $\frac{s-3}{2} = 0$, the leading coefficient vanishing simply and the period of the vanishing cycle of a nondegenerate point on a torus of dimension 2 having the exponent 0 with a logarithm. By Theorem 42.28(iv), $\operatorname{rank}(T_0 - 1) = 1$ and $(T_0 - 1)^2 = 0$: one Jordan block of size 2, a solution $g_0 = 1 + \cdots$ beside $g_0 \log t + \cdots$.

$s = 4$. $\mathbf{R}_2 = \vartheta^2 - 4y$, $\mathbf{R}_3 = \vartheta \mathbf{R}_2 - 6y\vartheta = \vartheta^3 - 10y\vartheta - 4y$, $\mathbf{R}_4 = \vartheta \mathbf{R}_3 - 6y\mathbf{R}_2 = \vartheta^4 - y(16\vartheta^2 + 14\vartheta + 4) + 24y^2$, and

$$\mathbf{Q}_4 = \mathbf{R}_5 = \vartheta \mathbf{R}_4 - 4y\mathbf{R}_3 = \vartheta^5 - y\,(20\vartheta^3 + 30\vartheta^2 + 18\vartheta + 4) + y^2\,(64\vartheta + 64),$$

with $\xi^5 - 20\eta\xi^3 + 64\eta^2\xi = \xi(\xi^2 - 16\eta)(\xi^2 - 4\eta)$; so $q_{4,1}(\vartheta) = -2(2\vartheta + 1)(5\vartheta^2 + 5\vartheta + 2)$ and $q_{4,2}(\vartheta) = 64(\vartheta + 1)$, and $c_{4,0}(x) = -x^3$, $c_{4,1}(x) = q_{4,1}(-x - 1) = 2(2x + 1)(5x^2 + 5x + 2)$, $c_{4,2}(x) =$

$q_{4,2}(-x-2)(x+1)^2 = -64(x+1)^3$. The closings $1, 4, 28, 256, 2716, \ldots$ satisfy the recurrence: at $j=2$, $8\cdot 28 - 72\cdot 4 + 64\cdot 1 = 0$. The exponents at 0 are the roots ρ of $c_{4,2}(\rho-1) = -64\rho^3$: $0, 0, 0$, the double list 0 and the extra exponent $\frac{s}{4} - 1 = 0$ of Theorem 42.28(iv). The monodromy at 0 is unipotent, with $\operatorname{rank}(T_0 - 1) = 2$ on a space of dimension 3 and $(T_0-1)^3 = 0$: one Jordan block of size 3. At ∞ the exponents are $1, 1, 1$, one block of size 3; at the sign values 16 and 4 they are $0, 1$ and $\frac{1}{2}$. □

Exercise 55.14 (The laws of the triangles; a wild high end)**.** Compare the roots of the laws of the triangles of classes with their native values and corner values, and show that the centre ray of J_6 is not tame at the high end (Definition 39.43).

Solution. The laws. By Proposition 42.22, with every class entering through the closings $\mathsf{M}_s(w) = \sum_{|v|=w} \binom{w}{v}^2$ of $\binom{[s]}{1}$ (Theorem 42.20(ii)),

$$\mathsf{C}_j(1) = \sum_{a+b+c=j} \binom{j}{a,b,c}^2 \mathsf{M}_{s_0}(a+b)\,\mathsf{M}_{s_1}(a+c)\,\mathsf{M}_{s_2}(b+c),$$

the exponents $(a+b, a+c, b+c)$ of the classes in $e_2(A)^j$ determining (a,b,c). Input: these closings, 900 to 9000 of them modulo primes near 2^{62}. Method: the operators of a fixed order and degree annihilating the closings form the kernel of a matrix; the least degree at each order and the growth of the kernel with the degree locate the order of the law, and the greatest common divisor of the symbols of all operators found is its symbol, whose roots are found by rational reconstruction. Check: two primes, and the same greatest common divisor at several pairs (order, degree). Receipts: `fast_closings.py`, `search2.py`, `order_check.py`, `bsearch.py` and their logs. Output, the roots as values of f^{-1} with their multiplicities:

list	n	order	native values	corner values	roots
$\Delta(2,1,1)$	4	4	25, 9, 1	1	25, 9, $1^{(2)}$
$\Delta(2,2,1)$	5	5	64, 16, 4, 1	4	64, 16, $4^{(2)}$, 1
$\Delta(3,1,1)$	5	6	49, 25, 9, 1	1	49, 25, 9, $1^{(3)}$
$\Delta(2,2,2)$	6	3	144, 16	16	144, $16^{(2)}$
$\Delta(3,2,1)$	6	13	121, 49, 25, 9, 1	**4**, 9, 1	121, 49, **4**, $25^{(2)}$, $9^{(3)}$, $1^{(5)}$
$\Delta(5,2,1)$	8	22	289, 169, 121, 49, 25, 9, 1	**4**, 25, 9, 1	289, 169, 121, $49^{(2)}$, $\mathbf{4}^{(2)}$, $25^{(4)}$, $9^{(4)}$, $1^{(7)}$
$\Delta(3,4,1)$	8	24	361, 169, 121, 81, 49, 25, 9, 1	**16**, **4**, 9, 1	361, 169, $121^{(2)}$, 81, $49^{(2)}$, $25^{(3)}$, **16**, $9^{(3)}$, **4**, $1^{(9)}$

The native and corner values are those of Exercise 55.11; in bold, the corner values of the odd classes that are not native values. Every root is a native value or a corner value, as Theorem 39.51 with Proposition 38.26 requires, and every corner value is a root. The corner values of an odd class C_i that no other source carries have the multiplicity $\frac{s_i-1}{2}$, the contribution of an odd corner in Proposition 42.33(c).

A wild high end. The root $\frac{1}{4}$ of the law of J_6 is not a native value, by Exercise 55.11(iv). By Theorem 39.44(iii) every nonzero root of the symbol of a ray tame at the high end is a native value; so the centre ray of J_6 is not tame: its insertion lattice is not finitely generated over the ring of the functions regular at $k=\infty$. If the classes of the insertions lay in $k^N \bigoplus_l A[b_l]$ for one N and masters $\mathbf{b}$, Λ_F would be a submodule of a finitely generated module over the noetherian ring A, hence finitely generated; so in every set of masters the coefficients of the classes of the insertions have poles at $k=\infty$ of unbounded order. The root $\frac{1}{4}$ is the corner value of the triple, an

asymptotic native value: the native gauges of the directions near the centre direction that carry it run into the wall of the triple. □

Exercise 55.15 (A mark of another norm, and the value 1 as a coincidence)**.** Let $\Delta_{\mathsf{m}}(s_0, s_1)$ be the triangle with the classes C_0, C_1 of s_0 odd and s_1 even marks and, at h_2, a mark of the norm $\mathsf{m} > 0$, its hinge pair $(\alpha_2, \mathsf{m}\alpha_2^{-1})$ (Definition 42.19): its closings are those of Exercise 55.14 with $\mathsf{M}_1(b+c)$ replaced by m^{b+c}, and at $\mathsf{m} = 1$ it is $\Delta(s_0, s_1, 1)$.

(i) List the sources in the hinge space (Theorem 42.31) at a generic norm, with their values and their contributions (Proposition 42.33).

(ii) Compare with the symbols of the laws at $\mathsf{m} = 2$.

(iii) At $\mathsf{m} = a^2$, $a \in \Sigma(s_0)$, $a > 0$, find the critical points of the two-sided core with C_0 on its hyperbola H_a and C_1 empty.

Solution. (i) Write $\varsigma = \sqrt{\mathsf{m}}$; the mark lies on the hyperbola $x_2 x_2' = \mathsf{m}$ and reads as a mark of the weight ς. By Theorem 42.31 each class is occupied, empty, silent or balanced.

- *Both classes on hyperbolas*, with the weights $a \in \Sigma(s_0)$ and $b \in \Sigma(s_1)$, $b \neq 0$: the weighted triangle of weights (a, b, ς) has only signs (Exercise 55.11(i)), with the values $e_2(a, \pm b, \pm\varsigma)^2$, that is $\big(ab \pm \varsigma(a+b)\big)^2$ and $\big(ab \pm \varsigma(a-b)\big)^2$ for $a, b > 0$: weighted points, each contributing 1.
- C_0 *silent*: the odd corners, of the values $b^2\mathsf{m}$, each contributing $\frac{s_0-1}{2}$ (Proposition 42.33(c)).
- C_0 *balanced*: nothing, since $m_{s_0}(O) = 0$ (Proposition 42.29(iv)).
- C_1 *balanced*: the weight-zero curves of C_1, of the values $a^2\mathsf{m}$; Proposition 42.33(e) applies to them away from their punctures, and for a pair Exercise 55.12 gives the quotient curve of the Euler characteristic -2.
- *A class empty*: the conditions $A_j + A_2 = A_j' + A_2' = 0$ put the other class at the norm of the mark, which at a generic m leaves only both classes empty, $x_0 = x_1 = -x_2$, $x_0' = x_1' = -x_2'$, of the value m^2, contributing $(s_0 - 1)(s_1 - 1)$ (Proposition 42.33(d)).

So the source count is the product

$$\Pi_{\mathsf{m}} = \prod_{a,b>0} \prod_{\pm} \big(\lambda - (ab \pm \varsigma(a+b))^2\big)\big(\lambda - (ab \pm \varsigma(a-b))^2\big) \cdot \prod_{b>0} (\lambda - b^2\mathsf{m})^{\frac{s_0-1}{2}} \cdot \prod_{a>0} (\lambda - a^2\mathsf{m})^2 \cdot (\lambda - \mathsf{m}^2)^{(s_0-1)(s_1-1)},$$

with the exponent 2 at the weight-zero values, of the degree $(s_0+1)s_1 + \frac{(s_0-1)s_1}{4} + (s_0+1) + (s_0 - 1)(s_1 - 1)$. Under the conditions of Theorem 42.32, every vanishing rank at a value other than the $a^2\mathsf{m}$ is at most its multiplicity in the other three factors.

(ii) Input: 2600 to 4600 closings modulo a prime near 2^{62}; method and check as in Exercise 55.14; receipts `fc_mu.py`, `search3.py`, `predict_sym2.py`, logs `law_*_mu2.log`. Output: for $(s_0, s_1) = (3,2), (5,2), (7,2), (3,4)$ at $\mathsf{m} = 2$, and $(3,2)$ at $\mathsf{m} = 3$, the symbol of the law is Π_{m} as a polynomial, of the orders 15, 24, 33 and 28; for $(3,2)$ at $\mathsf{m} = 2$ the rational roots are 8, $18^{(2)}$, $2^{(2)}$, $4^{(2)}$ and the other eight are simple. So at these norms the bound of (i) is attained, and the weight-zero curves contribute exactly 2.

(iii) Normalize the mark to $x_2 = 1$, $x_2' = \mathsf{m}$. C_1 empty means $x_0 + x_2 = 0$ and $x_0' + x_2' = 0$, so $x_0 = -1$, $x_0' = -\mathsf{m}$, and $x_0 x_0' = \mathsf{m}$, which on H_a needs $\mathsf{m} = a^2$. The derivative of the two-sided

core along H_a, in the direction $u\partial_u$ with $u = x_0$, is then $\mathsf{m}(\mathsf{m}x_1 - x_1')$, which gives $x_1' = \mathsf{m}x_1$. So the critical points form the curve

$$\bar{Z}_a = \{x_0 = -1,\ x_0' = -\mathsf{m},\ x_1 = w,\ x_1' = \mathsf{m}w\}, \qquad w \in \mathbb{C},$$

on which $K = -1$, $K' = -\mathsf{m}^2$ and $\Phi = \mathsf{m}^2$. On it lie the empty point ($w = -1$), the origin of the hinge plane of C_1 ($w = 0$), where the two corner points of the weight-zero curve of C_1 at the weight a meet, and the s_1 weighted points $(-a, \pm b, a)$ ($w = \pm b/a$), of the value $\big((-a)(\pm b) - a^2 \pm ab\big)^2 = a^4$; along $\bar{Z}_a$ the class C_1 has the norm $\mathsf{m}w^2$. At $\mathsf{m} = 1$ the list $\Delta(s_0, s_1, 1)$ sits at this coincidence with $a = 1$, and its value 1 is carried by the curve $\bar{Z}_1$. Its laws, computed as in Exercise 55.14 for $\Delta(3,2,1)$, $\Delta(5,2,1)$, $\Delta(7,2,1)$, $\Delta(3,4,1)$ and $\Delta(5,4,1)$ (receipts `predict_list.py`, logs `list_*.log`), have every value other than 1 with its multiplicity in Π_1, coincident values adding, and the value 1 with the multiplicity $(s_0 - 1)(s_1 - 1) + 3$, which is s_1 less than its exponent in Π_1; the same loss of s_1 at the value m^2 is found at $\mathsf{m} = 9$ for $(3,2)$, $(5,2)$, $(3,4)$ and at $\mathsf{m} = 25$ for $(5,2)$ (receipt `predict_coinc.py`). □

Chapter 56

Exercises on the content

The exercises of this chapter work the statements of Chapter 45 on the two smallest centre values met in the exercises on rays. The value ℓ of the list of three marks is placed in the content of level 3 as a combination of two trails of depth one and of two chains; the value of the half-lattice met at four marks is placed in the content of level 2, and the coset relation returns it to level 1. The cutting rule is then computed on the symbols of two trails, subset by subset, and the three parts of Theorem 45.9 are checked on them. Throughout, $\omega = e^{2\pi i/3}$, so that $\omega^3 = 1$, $\omega^2 + \omega + 1 = 0$, $\bar{\omega} = \omega^2 = \omega^{-1}$ and $\mu_3 = \{1, \omega, \omega^2\}$. Every number displayed is exact; decimal values are labelled renderings, and the receipts that recompute them are the scripts named in each solution.

56.1 Two centre values in the content

Exercise 56.1 (The values of three and four marks as trails and chains)**.** Let $\ell = P_{\binom{[3]}{1}}(\mathbf{1}; 1, 1) = 3\big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{1+3\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{2+3\mathbb{Z}})((0,\infty))\big)$ (Exercise 54.4) and $v = (\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\frac{1}{2}+\mathbb{Z}})((0,\infty))$ (Exercise 54.7).

(i) Write ℓ as a combination, with coefficients in $\mathbb{Q}(\mu_3)$, of the trails of level 3 of depth one at the index 2 and the frequencies $\frac{1}{3}$ and $\frac{2}{3}$ (Definition 45.1), and show that ℓ is a value of $\mathcal{C}_2^{(3)}$.

(ii) Write these two trails as chains of level 3 from 0 to 1 (Proposition 45.5(i)), check the first by integrating it, and write ℓ as a combination of chains.

(iii) Show that v is a value of $\mathcal{C}_3^{(2)}$ by writing it with the trails of level 2 at the index 3 and the frequencies 0 and $\frac{1}{2}$. Then use the coset relation to show that v is a value of $\mathcal{C}_3^{(1)}$, find the trail at the frequency $\frac{1}{2}$ in terms of the one at the frequency 0, and write v as a chain.

Solution. Receipt: `ct_values.py`.

(i) *The cosets as frequencies.* For an integer m, $\omega^m - \omega^{-m}$ is 0, $\omega - \omega^2$ and $\omega^2 - \omega$ for m in $3\mathbb{Z}$, $1 + 3\mathbb{Z}$ and $2 + 3\mathbb{Z}$, as $\omega^{-1} = \omega^2$. So the difference of the two indicators is

$$\mathbf{1}_{1+3\mathbb{Z}}(m) - \mathbf{1}_{2+3\mathbb{Z}}(m) = \frac{\omega^m - \omega^{-m}}{\omega - \omega^2} \qquad (m \in \mathbb{Z}).$$

At the index 2 every sum below converges absolutely, so the value of a lattice input at the cut 0 is the sum of its density times m^{-2} over the points $m > 0$ (Definition 5.2), and the sums may be split and recombined. With $\omega^{-m} = e^{2\pi i \cdot 2m/3}$,

$$(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{1+3\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{2+3\mathbb{Z}})((0,\infty)) = \sum_{m\geq 1} \frac{\omega^m - \omega^{-m}}{\omega-\omega^2}\, m^{-2}$$
$$= \frac{1}{\omega-\omega^2}\Big((\mathsf{T}_{2;(1)}[x]\, e^{2\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\, e^{4\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty))\Big),$$

the lattice inputs $e^{2\pi i a x}\mathbb{I}_{\mathbb{Z}}$ at the frequencies $a = \frac{1}{3}$ and $a = \frac{2}{3}$ on the counting lattice (Definition 5.2).

The constant. $(\omega-\omega^2)^2 = \omega^2 - 2\omega^3 + \omega^4 = \omega^2 + \omega - 2 = -3$. So $\frac{1}{\omega-\omega^2} = -\frac{\omega-\omega^2}{3}$ and $\frac{3}{\omega-\omega^2} = \omega^2 - \omega$, and

$$\ell = (\omega^2-\omega)\Big((\mathsf{T}_{2;(1)}[x]\, e^{2\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\, e^{4\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty))\Big).$$

The trails. For $d=1$, $\nu_1 = 2$ and $a_1 \in \{\frac{1}{3},\frac{2}{3}\} \subseteq \frac{1}{3}\mathbb{Z}$, the trail of level 3 of Definition 45.1 is $\big(\mathsf{T}_{2;I_1}[y]\, e^{2\pi i a_1 y}\,\mathbb{I}_{\mathbb{Z}}\big)(\{0<y\}) = \sum_{m\geq 1} e^{2\pi i a_1 m} m^{-2} = (\mathsf{T}_{2;(1)}[x]\, e^{2\pi i a_1 x}\mathbb{I}_{\mathbb{Z}})((0,\infty))$: it has the depth 1, the positive integer index 2 and a frequency in $\frac{1}{3}\mathbb{Z}$, and the condition at index one does not arise. Write T' and T'' for the trails at $\frac{1}{3}$ and $\frac{2}{3}$ in this solution. Then

$$\ell = \omega^2 T' - \omega T' - \omega^2 T'' + \omega T'',$$

the value of the combination $[\omega^2 T'] - [\omega T'] - [\omega^2 T''] + [\omega T'']$, with the rational coefficients ± 1, of the classes of the words ζT with $\zeta \in \mu_3$ and T a trail of level 3 of weight 2. So ℓ is a value of $\mathcal{C}_2^{(3)}$. Since $\bar\omega = \omega^2$, $T'' = \overline{T'}$, and $\ell = (\omega^2-\omega)(T'-\overline{T'}) = (-i\sqrt{3})(2i\,\mathrm{Im}\,T') = 2\sqrt{3}\,\mathrm{Im}\,T'$, with $\mathrm{Im}\,T' = \sum_{m\geq 1}\sin(\frac{2\pi m}{3})m^{-2} = \frac{\sqrt{3}}{2}\big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{1+3\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{2+3\mathbb{Z}})((0,\infty))\big)$, the S_2 of Exercise 54.4.

Rendering: both sides of the display for ℓ are $2.3439072386894588\ldots$.

(ii) *The chains.* Proposition 45.5(i) with $d=1$ and $\nu_1 = 2$ gives $c_1 = e^{2\pi i a_1}$, the letters c_1^{-1} and one 0, and the sign $(-1)^1$. At $a_1 = \frac{1}{3}$, $c_1 = \omega$ and $c_1^{-1} = \omega^2$; at $a_1 = \frac{2}{3}$, $c_1 = \omega^2$ and $c_1^{-1} = \omega$:

$$T' = -\mathrm{I}(0;\omega^2,0;1), \qquad T'' = -\mathrm{I}(0;\omega,0;1).$$

The check. For the ends 0 and 1 the path is $\gamma(t) = t$, and for a letter b with $|b| = 1$, $b \neq 1$ (Definition 45.4),

$$\mathrm{I}(0;b,0;1) = \int_{0<t_1<t_2<1} \frac{dt_1}{t_1-b}\,\frac{dt_2}{t_2}.$$

For $0 \leq t < 1$, $1 - t/b$ lies in the open disc of radius 1 about 1, where the principal logarithm is holomorphic; $\log(1-t/b)$ vanishes at $t=0$ and has the derivative $\frac{-1/b}{1-t/b} = \frac{1}{t-b}$, so the inner integral is $\log(1-t_2/b) = -\sum_{n\geq 1} b^{-n} t_2^n/n$. The series of absolute values, $\sum_n t_2^{n-1}/n$, integrates over $(0,1)$ to $\sum_n n^{-2} < \infty$, so the series integrates term by term, $\int_0^1 t_2^{n-1}\,dt_2 = \frac{1}{n}$:

$$\mathrm{I}(0;b,0;1) = -\sum_{n\geq 1} b^{-n} n^{-2}.$$

At $b = \omega^2$, $b^{-n} = \omega^{-2n} = \omega^n$, and $\mathrm{I}(0;\omega^2,0;1) = -\sum_n \omega^n n^{-2} = -T'$, as Proposition 45.5(i) states.

Rendering: the double integral is $0.5483113556160754\ldots - 0.6766277376064357\ldots i$, and so is $-T'$.

The value. Substituting,

$$\ell = (\omega^2-\omega)\big(-\mathrm{I}(0;\omega^2,0;1)+\mathrm{I}(0;\omega,0;1)\big) = (\omega-\omega^2)\big(\mathrm{I}(0;\omega^2,0;1)-\mathrm{I}(0;\omega,0;1)\big),$$

a combination of chains of level 3 from 0 to 1 with first letter not 0 and last letter not 1, as Proposition 45.5(iii) describes the values of $\mathcal{C}_2^{(3)}$.

(iii) *Level* 2. The positive points of $\frac{1}{2}+\mathbb{Z}$ are the $\frac{2m-1}{2}$, $m\geq 1$, so $v=\sum_{m\geq 1} 8(2m-1)^{-3}$ (Definition 5.2), absolutely convergent. The indicator of the odd integers is $\frac{1-(-1)^n}{2}=\frac{1-e^{\pi i n}}{2}$, so

$$v = 8\sum_{n\geq 1}\frac{1-e^{\pi i n}}{2}\,n^{-3} = 4\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) - 4\,(\mathsf{T}_{3;(1)}[x]\,e^{\pi i x}\mathbb{I}_{\mathbb{Z}})((0,\infty)).$$

$(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ and $(\mathsf{T}_{3;(1)}[x]\,e^{\pi i x}\mathbb{I}_{\mathbb{Z}})((0,\infty))$ are the trails of depth one at the index 3 and the frequencies 0 and $\frac{1}{2}$, both in $\frac{1}{2}\mathbb{Z}$: trails of level 2. So v is a value of $\mathcal{C}_3^{(2)}$, as Proposition 45.3(i) gives directly for the coset $b=\frac{1}{2}\in\frac{1}{2}\mathbb{Z}$ at the frequency 0, with $M=2$ and $M'=1$.

Level 1. The coset relation of Exercise 54.7, Theorem 5.12(i) at $q=2$ and $b=0$, is $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) + v = 8\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$. So

$$v = 7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)),$$

a rational multiple of a trail of level 1, and v is a value of $\mathcal{C}_3^{(1)}$. Comparing the two expressions of v, $4\,(\mathsf{T}_{3;(1)}[x]\,e^{\pi i x}\mathbb{I}_{\mathbb{Z}})((0,\infty)) = 4\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) - 7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$:

$$(\mathsf{T}_{3;(1)}[x]\,e^{\pi i x}\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -\tfrac{3}{4}\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)).$$

The chain. Proposition 45.5(i) with $d=1$, $\nu_1=3$ and $a_1=0$ gives $c_1=1$, the letters $1,0,0$, and $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -\mathrm{I}(0;1,0,0;1)$; so $v=-7\,\mathrm{I}(0;1,0,0;1)$.

Rendering: $v=8.4143983221171599\ldots$, the value of both expressions above; the ratio of the trail at the frequency $\frac{1}{2}$ to the trail at the frequency 0 renders as -0.75, and the triple integral $\mathrm{I}(0;1,0,0;1)$ as $-1.2020569031595942\ldots$.

Answer.

$$\begin{aligned}\ell &= (\omega^2-\omega)\Big((\mathsf{T}_{2;(1)}[x]\,e^{2\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,e^{4\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty))\Big)\\ &= (\omega-\omega^2)\big(\mathrm{I}(0;\omega^2,0;1)-\mathrm{I}(0;\omega,0;1)\big),\end{aligned}$$

a value of $\mathcal{C}_2^{(3)}$. $v = 4\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) - 4\,(\mathsf{T}_{3;(1)}[x]\,e^{\pi i x}\mathbb{I}_{\mathbb{Z}})((0,\infty))$ is a value of $\mathcal{C}_3^{(2)}$, and by the coset relation $v = 7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -7\,\mathrm{I}(0;1,0,0;1)$, a value of $\mathcal{C}_3^{(1)}$, with $(\mathsf{T}_{3;(1)}[x]\,e^{\pi i x}\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -\frac{3}{4}\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$. □

56.2 The cutting rule on two trails

Exercise 56.2 (The cutting rule on $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ and on the trail of index 2 at the frequency $\frac{1}{3}$)**.** Let σ_3 be the symbol of the trail $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ of level 1, and σ' that of the trail $(\mathsf{T}_{2;(1)}[x]\,e^{2\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty))$ of level 3 (Definition 45.7).

(i) Compute $\Delta\sigma_3$ and $\Delta\sigma'$ (Definition 45.8), subset by subset.

(ii) Check the three parts of Theorem 45.9 on σ_3 and σ': coassociativity and the counit, the weights, and the compatibility with the reversal and the rotations.

(iii) Read the left factors of positive weight as symbols of trails (Proposition 45.5(ii)), and compute the chains of the two factors of weight one in $\Delta\sigma'$.

Solution. Receipts: `ct_cutting.py` for (i) and (ii), `ct_values.py` for the renderings in (iii).

The symbols. Both trails have depth $d = 1$. For $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$, $\nu_1 = 3$ and $c_1 = 1$; for $(\mathsf{T}_{2;(1)}[x]\,e^{2\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty))$, $\nu_1 = 2$ and $c_1 = \omega$, $c_1^{-1} = \omega^2$. So, with $x = \mathrm{I}^{\mathfrak{s}}(0;1,0,0;1)$ and $y = \mathrm{I}^{\mathfrak{s}}(0;\omega^2,0;1)$,

$$\sigma_3 = -x, \qquad \sigma' = -y.$$

Δ is $\mathbb{Q}(\mu_M)$-linear, so $\Delta\sigma_3 = -\Delta x$ and $\Delta\sigma' = -\Delta y$. In $\mathfrak{S}_M$ a run with no letters is 1, and a run of at least one letter between equal ends is 0 (Definition 45.7); these two rules decide every right factor below.

(i) *The cutting rule on x.* The entries are $a_0 = 0$, $a_1 = 1$, $a_2 = 0$, $a_3 = 0$, $a_4 = 1$, and $w = 3$. For each $S \subseteq \{1,2,3\}$, the left factor keeps the letters of S between the ends 0 and 1, and the right factors are the runs between consecutive kept positions $s_0 = 0 < s_1 < \cdots < s_{|S|+1} = 4$:

S	left factor	runs, and the term
$\varnothing$	1	$\mathrm{I}^{\mathfrak{s}}(0;1,0,0;1) = x$: the term $1 \otimes x$
$\{1\}$	$\mathrm{I}^{\mathfrak{s}}(0;1;1)$	$\mathrm{I}^{\mathfrak{s}}(0;\varnothing;1) = 1$, $\mathrm{I}^{\mathfrak{s}}(1;0,0;1) = 0$: no term
$\{2\}$	$\mathrm{I}^{\mathfrak{s}}(0;0;1)$	$\mathrm{I}^{\mathfrak{s}}(0;1;0) = 0$: no term
$\{3\}$	$\mathrm{I}^{\mathfrak{s}}(0;0;1)$	$\mathrm{I}^{\mathfrak{s}}(0;1,0;0) = 0$: no term
$\{1,2\}$	$\mathrm{I}^{\mathfrak{s}}(0;1,0;1)$	1, 1, $\mathrm{I}^{\mathfrak{s}}(0;0;1)$
$\{1,3\}$	$\mathrm{I}^{\mathfrak{s}}(0;1,0;1)$	1, $\mathrm{I}^{\mathfrak{s}}(1;0;0)$, 1
$\{2,3\}$	$\mathrm{I}^{\mathfrak{s}}(0;0,0;1)$	$\mathrm{I}^{\mathfrak{s}}(0;1;0) = 0$: no term
$\{1,2,3\}$	x	1, 1, 1, 1: the term $x \otimes 1$

With $z = \mathrm{I}^{\mathfrak{s}}(0;1,0;1)$ and $R = \mathrm{I}^{\mathfrak{s}}(0;0;1) + \mathrm{I}^{\mathfrak{s}}(1;0;0)$,

$$\Delta x = x \otimes 1 + 1 \otimes x + z \otimes R.$$

The cutting rule on y. The entries are $a_0 = 0$, $a_1 = \omega^2$, $a_2 = 0$, $a_3 = 1$, and $w = 2$:

S	left factor	runs, and the term
$\varnothing$	1	y: the term $1 \otimes y$
$\{1\}$	$\mathrm{I}^{\mathfrak{s}}(0;\omega^2;1)$	$\mathrm{I}^{\mathfrak{s}}(0;\varnothing;\omega^2) = 1$, $\mathrm{I}^{\mathfrak{s}}(\omega^2;0;1)$
$\{2\}$	$\mathrm{I}^{\mathfrak{s}}(0;0;1)$	$\mathrm{I}^{\mathfrak{s}}(0;\omega^2;0) = 0$: no term
$\{1,2\}$	y	1, 1, 1: the term $y \otimes 1$

With $A = \mathrm{I}^{\mathfrak{s}}(0;\omega^2;1)$ and $B = \mathrm{I}^{\mathfrak{s}}(\omega^2;0;1)$,

$$\Delta y = y \otimes 1 + 1 \otimes y + A \otimes B.$$

(ii) *The pieces are primitive.* A formal chain u of weight one has two subsets: $S = \varnothing$ gives $1 \otimes u$ and $S = \{1\}$ gives $u \otimes 1$, its two runs being empty. So $\Delta u = u \otimes 1 + 1 \otimes u$ for $u = \mathrm{I}^{\mathfrak{s}}(0;0;1)$, $\mathrm{I}^{\mathfrak{s}}(1;0;0)$, A and B, and $\Delta R = R \otimes 1 + 1 \otimes R$ by linearity. For z, with the entries $0,1,0,1$: $S = \{1\}$ leaves the run $\mathrm{I}^{\mathfrak{s}}(1;0;1) = 0$ and $S = \{2\}$ the run $\mathrm{I}^{\mathfrak{s}}(0;1;0) = 0$, so $\Delta z = z \otimes 1 + 1 \otimes z$ as well.

Coassociativity. Δ is an algebra homomorphism with $\Delta 1 = 1 \otimes 1$, so on y

$$(\Delta \otimes \mathrm{id})\Delta y = 1 \otimes 1 \otimes y + (y \otimes 1 + 1 \otimes y + A \otimes B) \otimes 1 + (A \otimes 1 + 1 \otimes A) \otimes B,$$

$$(\mathrm{id}\otimes\Delta)\Delta y = y\otimes 1\otimes 1 + 1\otimes(y\otimes 1 + 1\otimes y + A\otimes B) + A\otimes(B\otimes 1 + 1\otimes B),$$

and both are the sum of the six tensors $1\otimes 1\otimes y$, $1\otimes y\otimes 1$, $y\otimes 1\otimes 1$, $A\otimes B\otimes 1$, $A\otimes 1\otimes B$ and $1\otimes A\otimes B$. On x the same expansion, with z and R primitive, gives on both sides the six tensors $1\otimes 1\otimes x$, $1\otimes x\otimes 1$, $x\otimes 1\otimes 1$, $z\otimes R\otimes 1$, $z\otimes 1\otimes R$ and $1\otimes z\otimes R$.

The counit. $\varepsilon(1) = 1$ and ε vanishes on the formal chains, so $(\varepsilon\otimes\mathrm{id})\Delta x = x + \varepsilon(z)R = x$ and $(\mathrm{id}\otimes\varepsilon)\Delta x = x + z\,\varepsilon(R) = x$, and in the same way on y. This is Theorem 45.9(i) on the two symbols.

The weights. The terms of Δx have the weights $(3,0)$, $(0,3)$ and $(2,1)$, those of Δy the weights $(2,0)$, $(0,2)$ and $(1,1)$; the sums are 3 and 2, and $\Delta x - x\otimes 1 - 1\otimes x = z\otimes R$ and $\Delta y - y\otimes 1 - 1\otimes y = A\otimes B$ have both factors of positive weight: Theorem 45.9(ii).

The reversal. $\varrho y = (-1)^2\,\mathrm{I}^{\mathfrak{s}}(1;0,\omega^2;0)$. Its entries $1,0,\omega^2,0$ give: $S=\varnothing$, $1\otimes\varrho y$; $S=\{1\}$, the left factor $\mathrm{I}^{\mathfrak{s}}(1;0;0)$ and the run $\mathrm{I}^{\mathfrak{s}}(0;\omega^2;0) = 0$, no term; $S=\{2\}$, the left factor $\mathrm{I}^{\mathfrak{s}}(1;\omega^2;0)$ and the runs $\mathrm{I}^{\mathfrak{s}}(1;0;\omega^2)$ and 1; $S=\{1,2\}$, $\varrho y\otimes 1$. On the other side $\varrho A = -\mathrm{I}^{\mathfrak{s}}(1;\omega^2;0)$ and $\varrho B = -\mathrm{I}^{\mathfrak{s}}(1;0;\omega^2)$, so

$$\Delta\varrho y = \varrho y\otimes 1 + 1\otimes\varrho y + \mathrm{I}^{\mathfrak{s}}(1;\omega^2;0)\otimes\mathrm{I}^{\mathfrak{s}}(1;0;\omega^2) = (\varrho\otimes\varrho)\Delta y.$$

$\varrho x = (-1)^3\,\mathrm{I}^{\mathfrak{s}}(1;0,0,1;0)$. Of the eight subsets of the entries $1,0,0,1,0$, those with a term are $\varnothing$, $\{1,2,3\}$, $\{1,3\}$, with the left factor $\mathrm{I}^{\mathfrak{s}}(1;0,1;0)$ and the run $\mathrm{I}^{\mathfrak{s}}(0;0;1)$, and $\{2,3\}$, with the same left factor and the run $\mathrm{I}^{\mathfrak{s}}(1;0;0)$; the other four leave a run between equal ends. So $\Delta\varrho x = \varrho x\otimes 1 + 1\otimes\varrho x - \mathrm{I}^{\mathfrak{s}}(1;0,1;0)\otimes R$. On the other side $\varrho z = (-1)^2\,\mathrm{I}^{\mathfrak{s}}(1;0,1;0)$ and $\varrho R = -\mathrm{I}^{\mathfrak{s}}(1;0;0) - \mathrm{I}^{\mathfrak{s}}(0;0;1) = -R$, so $(\varrho\otimes\varrho)(z\otimes R) = -\mathrm{I}^{\mathfrak{s}}(1;0,1;0)\otimes R$, and $\Delta\varrho x = (\varrho\otimes\varrho)\Delta x$.

The rotations. ρ_λ, $\lambda\in\mu_3$, multiplies every entry by λ and fixes the entry 0. It changes neither which ends of a run are equal nor which runs are empty, so the same subsets give the terms of $\Delta\rho_\lambda y$, with every entry multiplied by λ: $\Delta\rho_\lambda y = \rho_\lambda y\otimes 1 + 1\otimes\rho_\lambda y + \mathrm{I}^{\mathfrak{s}}(0;\lambda\omega^2;\lambda)\otimes\mathrm{I}^{\mathfrak{s}}(\lambda\omega^2;0;\lambda) = (\rho_\lambda\otimes\rho_\lambda)\Delta y$. At level 1 the only rotation of x is the identity. This is Theorem 45.9(iii) on the two symbols.

(iii) *The left factor of* Δx. The chain $\mathrm{I}(0;1,0;1)$ has the first letter $1\neq 0$ and the last letter $0\neq 1$. In Proposition 45.5(ii) its one nonzero letter is at $j_1 = 1$, with $j_2 = w+1 = 3$, so $d=1$, $c_1=1$, $\nu_1 = 2$, $c_2 = 1$, and the frequency $a_1' = 0$: $\mathrm{I}(0;1,0;1) = -(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$, and $z = -\sigma_2$ with σ_2 the symbol of $(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$. The right factor $R = \mathrm{I}^{\mathfrak{s}}(0;0;1) - \varrho\,\mathrm{I}^{\mathfrak{s}}(0;0;1)$ is a formal chain of weight one minus its reversal; the first letter of $\mathrm{I}^{\mathfrak{s}}(0;0;1)$ is its first end, so it has no realization (Definition 45.7), and $\int_0^1 dt/t$ diverges. Rendering: $\mathrm{I}(0;1,0;1) = -1.6449340668482264\ldots$.

The factors of Δy. A has the letter $\omega^2\neq 0,1$. In Proposition 45.5(ii), $d=1$, $c_1=\omega$, $\nu_1 = 1$ and $c_2 = 1$, with the frequency $a_1' = \frac{1}{3}$, $e^{2\pi i a_1'} = \omega$: $\mathrm{I}(0;\omega^2;1)$ is minus the trail of level 3 of depth one at the index 1 and the frequency $\frac{1}{3}$, $\lim_N\sum_{m\le N}\omega^m m^{-1}$, which is a trail because $e^{2\pi i/3}\neq 1$ (Definition 45.1); A is minus its symbol. On the path $\gamma(t) = t$, $t-\omega^2 = t + \frac{1}{2} + \frac{\sqrt{3}}{2}i$ has the imaginary part $\frac{\sqrt{3}}{2} > 0$, so the principal logarithm is continuous along it and

$$\mathrm{I}(0;\omega^2;1) = \int_0^1\frac{dt}{t-\omega^2} = \log\Big(\frac{3}{2}+\frac{\sqrt{3}}{2}i\Big) - \log\Big(\frac{1}{2}+\frac{\sqrt{3}}{2}i\Big) = \Big(\frac{1}{2}\log 3 + \frac{\pi i}{6}\Big) - \frac{\pi i}{3} = \frac{1}{2}\log 3 - \frac{\pi i}{6}.$$

B has the ends ω^2 and 1, so it is a chain between two singular points with no end at 0, read as it stands. Its letter 0 is not on the open segment from ω^2 to 1 and differs from both ends, so the chain is defined and converges (Definition 45.4, Proposition 45.6(i)). On $\gamma(t) = \omega^2 + t(1-\omega^2) = -\frac{1}{2} + \frac{3}{2}t - \frac{\sqrt{3}}{2}(1-t)i$ the imaginary part is negative for $t<1$, so the argument of $\gamma(t)$ runs

continuously from $-\frac{2\pi}{3}$ to 0 and the modulus from 1 to 1:

$$\mathrm{I}(\omega^2;0;1)=\int_0^1\frac{\gamma'(t)\,dt}{\gamma(t)}=\log 1-\log\omega^2=0-\Big(-\frac{2\pi i}{3}\Big)=\frac{2\pi i}{3}.$$

Rendering: the integrals render as $0.5493061443340548\ldots-0.5235987755982988\ldots i$ and $2.0943951023931954\ldots i$.

Answer. With σ_2 the symbol of $(\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$ and $\sigma_1'=-\mathrm{I}^{\mathfrak{s}}(0;\omega^2;1)$ the symbol of the trail of index 1 at the frequency $\frac{1}{3}$,

$$\Delta\sigma_3=\sigma_3\otimes 1+1\otimes\sigma_3+\sigma_2\otimes\big(\mathrm{I}^{\mathfrak{s}}(0;0;1)+\mathrm{I}^{\mathfrak{s}}(1;0;0)\big),\qquad \Delta\sigma'=\sigma'\otimes 1+1\otimes\sigma'+\sigma_1'\otimes\mathrm{I}^{\mathfrak{s}}(\omega^2;0;1).$$

Both are coassociative and counital, graded by the weight, and compatible with the reversal and the rotations, as Theorem 45.9 states. The left factors σ_2 and σ_1' are symbols of trails; the right factor $\mathrm{I}^{\mathfrak{s}}(\omega^2;0;1)$ is a chain between the singular points ω^2 and 1 with the value $\frac{2\pi i}{3}$, and $\mathrm{I}(0;\omega^2;1)=\frac{1}{2}\log 3-\frac{\pi i}{6}$. □

56.3 Separation of the content

The two exercises of this section work the separation of the content (Section 45.5). The first runs the separation procedure at level 1 through weight 14; the second places the two smallest centre values among the separating generators. Throughout, for an index $\mathbf{k}=(k_1,\ldots,k_d)$ with $k_1\geq 2$,

$$T(\mathbf{k})=\sum_{y_1>\cdots>y_d>0}\prod_{i=1}^{d}y_i^{-k_i},$$

the trail of level 1 with the data $(k_d,\ldots,k_1)$ (Definition 45.1), so that $T(N)=(\mathsf{T}_{N;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$; by Proposition 45.5(i) its chain is

$$T(\mathbf{k})=(-1)^d\,\mathrm{I}\big(0;\,1,0^{k_d-1},\,1,0^{k_{d-1}-1},\,\ldots,\,1,0^{k_1-1};\,1\big),$$

the blocks of the word read from the left giving the index from the right.

Exercise 56.3 (The content of level one through weight fourteen)**.** Run the separation procedure (Definition 45.17) at level 1 for $N=2,\ldots,14$, with R_k the stuffle product of trails (Proposition 45.2(ii)), the shuffle product of their chains and the relation of index one,

$$\sum_{i=1}^{d}T(k_1,\ldots,k_i+1,\ldots,k_d)=\sum_{i=1}^{d}\sum_{j=0}^{k_i-2}T(k_1,\ldots,k_{i-1},k_i-j,j+1,k_{i+1},\ldots,k_d)$$

for every index $\mathbf{k}$ of weight $k-1$, and with $\mathcal{R}$ the odd lengths from 3 to $N-2$. Show that it succeeds in every weight, conclude that every relation among the motivic values of the trails of level 1 of weight at most 14 is a consequence of these three relations, and find polynomial generators of the motivic content of level 1 through weight 14.

Solution. Receipts: `completeness/content_separation.py`, `completeness/small_weights.py` and `completeness/generators_basis.py`, with their logs.

The relations hold for motivic values. The stuffle and the shuffle products and the relation of index one are the double shuffle relations of the trails of level 1, and they hold for the motivic chains

of level 1 (Racinet and Furusho; they apply because the trails of level 1 are the multiple sums of Definition 45.1 at the frequency 0, whose chains are the iterated integrals of Proposition 45.5). The shuffle product is written on the trails as follows: if u and v are the words of $T(\mathbf{k})$ and $T(\mathbf{l})$, every word of u shuffled with v has the letters 1 of both, so the signs $(-1)^d$ agree and $T(\mathbf{k})T(\mathbf{l})$ is the sum of the trails of the shuffled words.

Weights 2 *and* 3. V_2 is the line of $T(2)$: no relation has weight 2. In weight 3 the trails are $T(3)$ and $T(2,1)$, and the relation of index one at $\mathbf{k}=(2)$ reads $T(3)=T(2,1)$; so V_3 is the line of $T(3)$. There are no cuts ($\mathcal{R}$ is empty), and the joint kernel is the line of $T(N)$, whose value is positive: step (4) succeeds, and by Theorem 45.18, with nothing to assume below, V_2 and V_3 map injectively.

Weight 4. The trails are $T(4), T(3,1), T(2,2), T(2,1,1)$. The word of $T(2)$ is 10, and 10 shuffled with 10 is $2\cdot 1010+4\cdot 1100$, the words of $T(2,2)$ and $T(3,1)$; the stuffle of (2) with (2) is $2\,(2,2)+(4)$. So R_4 is

$$T(2)^2 = 2T(2,2)+4T(3,1) = 2T(2,2)+T(4),$$
$$T(4) = T(3,1)+T(2,2), \qquad T(3,1)+T(2,2) = T(2,1,1),$$

the last two the relation of index one at (3) and at $(2,1)$. Their rank is 3, and

$$V_4 = \mathbb{Q}\,T(2,2), \qquad T(4) = \tfrac{4}{3}T(2,2), \quad T(3,1) = \tfrac{1}{3}T(2,2), \quad T(2,1,1) = \tfrac{4}{3}T(2,2).$$

Again $\mathcal{R}$ is empty and the joint kernel is the line of $T(4)$, of positive value.

Weight 5. The eight trails reduce to the basis $T(2,3), T(3,2)$:

$$T(5) = \tfrac{6}{5}T(2,3)+\tfrac{4}{5}T(3,2), \qquad T(4,1) = T(3,1,1) = \tfrac{1}{5}T(2,3)-\tfrac{1}{5}T(3,2),$$
$$T(2,1,2) = T(2,3), \qquad T(2,2,1) = T(3,2), \qquad T(2,1,1,1) = T(5),$$
$$T(2)T(3) = \tfrac{11}{5}T(2,3)+\tfrac{9}{5}T(3,2).$$

$\mathcal{R}=\{3\}$, and $V_3/\mathfrak{v}_3 = V_3$ is the line of $T(3)$. The cut D_3 of $T(2,3)$, by Definition 45.14(iii) on its chain $\mathrm{I}(0;1,0,0,1,0;1)$, with $a_0=0$, $(a_1,\dots,a_5)=(1,0,0,1,0)$, $a_6=1$:

- $p=0$: the run $1,0,0$ between 0 and $a_4=1$ is $\mathrm{I}(0;1,0,0;1) = -T(3)$, and the kept letters $1,0$ give $\mathrm{I}(0;1,0;1) = -T(2)$; the term is $[T(3)]\otimes T(2)$.
- $p=1$: the run $0,0,1$ between $a_1=1$ and $a_5=0$ is $\mathrm{I}(1;0,0,1;0) = (-1)^3\mathrm{I}(0;1,0,0;1) = T(3)$ by the reversal (Proposition 45.6(iii)); the kept letters $1,0$ give $-T(2)$; the term is $-[T(3)]\otimes T(2)$.
- $p=2$: the run $0,1,0$ between $a_2=0$ and $a_6=1$ begins with its first end; the regularization removes the leading 0: $\mathrm{I}(0;0,1,0;1) = -\mathrm{I}(0;1,0,0;1) - \mathrm{I}(0;1,0,0;1) = 2\,T(3)$, the two words being the insertions of 0 after each letter of $1,0$; the kept letters $1,0$ give $-T(2)$; the term is $-2[T(3)]\otimes T(2)$.

So $\mathsf{D}_3T(2,3) = -2\,[T(3)]\otimes T(2)$, and in the same way $\mathsf{D}_3T(3,2) = 3\,[T(3)]\otimes T(2)$. The cut vanishes on every relation of weight 5 (step (3), receipt). Its kernel on V_5 is the line of $3T(2,3)+2T(3,2) = \frac{5}{2}T(5)$, of positive value.

Weight 6. The basis is $T(3,3), T(2,2,2)$, with $T(6) = \frac{16}{3}T(2,2,2)$; $\mathcal{R}=\{3\}$ and

$$\mathsf{D}_3T(3,3) = [T(3)]\otimes T(3), \qquad \mathsf{D}_3T(2,2,2) = 0.$$

The kernel is the line of $T(2,2,2)$, which is that of $T(6)$.

Weight 7. The basis is $T(2,2,3), T(2,3,2), T(3,2,2)$, and $\mathcal{R} = \{3,5\}$. V_4 is the line of $T(2,2)$; $V_5/\mathfrak{v}_5$ is the line of the class of $T(5)$, the products being the line of $T(2)T(3)$. On the basis, in the order given,

$$\mathsf{D}_3 = (-2,\ 0,\ 3)\,[T(3)] \otimes T(2,2), \qquad \mathsf{D}_5 = \big(12,\ -\tfrac{11}{2},\ -\tfrac{15}{2}\big)\,[T(5)] \otimes T(2).$$

Their joint kernel is the line of $(33, 42, 22)$, and $T(7) = \frac{16}{151}\big(33\,T(2,2,3) + 42\,T(2,3,2) + 22\,T(3,2,2)\big)$: the line of $T(7)$.

Weights 8 *to* 14*, by machine.* Input: the 2^{N-2} trails of weight N, as their words; the relations R_N, one for each pair of words of weights k and $N-k$, $2 \le k \le N/2$ (stuffle minus shuffle), and one for each index of weight $N-1$ (index one): 1672 relations in weight 12, 7696 in weight 14. Method: exact row reduction over $\mathbb{Q}$ with the trails of indices 2 and 3 placed last, so that they are the free columns when they span; the reading of runs and kept chains by the regularization at the ends, as in weight 5; the cuts of every trail and of every relation; the rank of the cut matrix on the basis. Output:

N	2	3	4	5	6	7	8	9	10	11	12	13	14
$\dim V_N$	1	1	1	2	2	3	4	5	7	9	12	16	21
$\dim V_N/\mathfrak{v}_N$	0	1	0	1	0	1	1	1	1	2	2	3	3
rank of the cuts	0	0	0	1	1	2	3	4	6	8	11	15	20

with $\dim V_N = d_N$, $\sum_N d_N x^N = 1/(1-x^2-x^3)$, and the trails of indices 2 and 3 a basis in every weight. Checks: every cut vanishes on every relation (step (3)); in every weight the rank of the cuts is $\dim V_N - 1$ and $T(N)$ lies in their kernel, so the joint kernel is the line of $T(N)$, of positive value (step (4)). Receipt: `content_separation.py 14` and its log.

Conclusion. Theorem 45.18 applies at $N = 2$ and 3 with nothing below, and at each $N \le 14$ its hypothesis is its conclusion at the weights below. So $V_N \to \mathcal{P}^{(1)}[N]$ is injective for $N \le 14$. The motivic values are graded by the weight, so a relation among trails of weights at most 14 splits into its homogeneous parts, each a consequence of the three relations.

Polynomial generators. In each weight the products of the generators found in lower weights are reduced in V_N, and trails are added, those with all indices odd first, while they raise the rank (receipt `generators_basis.py 14`). The generators found are

$$T(2),\ T(3),\ T(5),\ T(7),\ T(9),\ T(11),\ T(13),$$
$$T(3,5),\ T(3,7),\ T(3,3,5),\ T(3,9),\ T(2,2,3,5),$$
$$T(3,3,7),\ T(3,5,5),\ T(3,11),\ T(5,9),\ T(3,3,3,5),$$

in the weights $2,3,5,7,9,11,13,8,10,11,12,12,13,13,14,14,14$: one for $\mathbb{L}^2$ and one for each Lyndon word in the letters $x_3 < x_5 < \cdots$ of weight at most 14, and their monomials are a basis of V_N in every weight. In weight 12 the products of lower generators span 10 dimensions; $T(3,9)$ adds one, and $T(5,7)$, $T(7,5)$, $T(9,3)$, $T(3,3,3,3)$ add none; the products together with all 56 trails of depth at most three span $11 = d_{12} - 1$, so the second generator of weight 12 has depth at least four, and $T(2,2,3,5)$ is one. In weight 14, $T(3,11)$ and $T(5,9)$ are independent modulo products.

Answer. The procedure succeeds in every weight from 2 to 14, the joint kernel of the cuts being the line of $T(N)$; every relation among the motivic values of the trails of level 1 of weight at most 14 is a consequence of the stuffle product, the shuffle product of chains and the relation of index one; the dimensions are d_N, with the trails of indices 2 and 3 as a basis; and the motivic content of level 1 through weight 14 is the polynomial algebra on the seventeen trails above. □

Exercise 56.4 (The two smallest centre values are separating generators)**.** Let ℓ be the value of the list of three marks at its centre and v the value of the half-lattice at four marks (Exercise 56.1). Show that $\ell = (\omega^2 - \omega)\,\mathsf{w}_2$ with w_2 the separating generator of weight 2 at level 3, and $v = 7\,\mathsf{w}_3$ with w_3 the separating generator of weight 3 at level 1 (Definition 45.14(iv)); check that their cuts vanish, and read their values.

Solution. The list of three marks. By Exercise 56.1(i), $\ell = (\omega^2-\omega)\big((\mathsf{T}_{2;(1)}[x]\,e^{2\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,e^{4\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty))\big)$, with $\omega = e^{2\pi i/3}$. The frequency enters through $e^{2\pi i a y}$ at integers y, so $(\mathsf{T}_{2;(1)}[x]\,e^{4\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty)) = (\mathsf{T}_{2;(1)}[x]\,e^{-2\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty))$, and

$$\ell = (\omega^2-\omega)\,\mathsf{w}_2, \qquad \mathsf{w}_2 = (\mathsf{T}_{2;(1)}[x]\,2i\sin(\tfrac{2\pi x}{3})\,\mathbb{I}_{\mathbb{Z}})((0,\infty)),$$

the separating generator of weight 2 at level 3 (Definition 45.14(iv), $N=2$ even, $M=3$).

Its cut. The only length below 2 is $r = 1$. By Exercise 56.1(ii) the chains are $(\mathsf{T}_{2;(1)}[x]\,e^{2\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -\mathrm{I}(0;\omega^2,0;1)$ and $(\mathsf{T}_{2;(1)}[x]\,e^{4\pi i x/3}\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -\mathrm{I}(0;\omega,0;1)$. For $\mathrm{I}(0;\beta,0;1)$, $\beta \in \{\omega,\omega^2\}$: at $p=0$ the run β lies between the ends 0 and 0, equal, and gives 0; at $p=1$ the run 0 lies between β and 1, and $\mathrm{I}(\beta;0;1) = \log 1 - \log\beta$ read motivically is a rational multiple of $\mathbb{L}$, which is 0 in $\mathfrak{n}^{(3)}[1]$. So $\mathsf{D}_1\mathsf{w}_2^{\mathfrak{m}} = 0$, as Theorem 45.15(ii) says for every separating generator.

Its value. With $\chi(y) = (\omega^y - \omega^{-y})/(\omega-\omega^2)$, which is $1,-1,0$ on $1+3\mathbb{Z}$, $2+3\mathbb{Z}$, $3\mathbb{Z}$, and $\omega - \omega^2 = i\sqrt{3}$,

$$\mathsf{w}_2 = \sum_{y\geq 1}\frac{\omega^y-\omega^{-y}}{y^2} = i\sqrt{3}\,\big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{1+3\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{2+3\mathbb{Z}})((0,\infty))\big) = \frac{i\,\ell}{\sqrt{3}},$$

since $\ell = 3\big((\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{1+3\mathbb{Z}})((0,\infty)) - (\mathsf{T}_{2;(1)}[x]\,\mathbb{I}_{2+3\mathbb{Z}})((0,\infty))\big)$; and $\ell = 2.3439072386894588\ldots$ (rendering, Exercise 56.1) is positive, as the product of Theorem 45.15(ii) says. The value of w_2 is imaginary and that of $\mathbb{L}^2$ is real, $-4\Gamma(\frac12)^4$, so an element $c\,\mathsf{w}_2^{\mathfrak{m}} + b\,\mathbb{L}^2$ has the readout $c = \sqrt{3}\,\mathrm{Im}(\cdot)/\ell$ and $b = -\,\mathrm{Re}(\cdot)/(4\Gamma(\frac12)^4)$ of its value. Over the coefficients $\mathbb{Q}(\mu_3)$ the motivic value of ℓ is $(\omega^2-\omega)\,\mathsf{w}_2^{\mathfrak{m}}$, a separating generator times an algebraic number.

The half-lattice at four marks. By Exercise 56.1(iii), $v = 7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = 7\,\mathsf{w}_3$ at level 1. The chain is $(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty)) = -\mathrm{I}(0;1,0,0;1)$; its runs of one or two letters are bounded by equal ends, or are letters 0 between 1 and an end, read as $(-\log 1)^r/r! = 0$; so D_1 and D_2 vanish, and indeed $\mathfrak{n}^{(1)}[1] = \mathfrak{n}^{(1)}[2] = 0$, the motivic content of level 1 having nothing in weight 1 and only $\mathbb{Q}\,\mathbb{L}^2$ in weight 2. Its value $v = 8.4143983221171599\ldots$ (rendering) is positive.

Answer. $\ell = (\omega^2-\omega)\,\mathsf{w}_2$ at level 3, with w_2 of value $i\ell/\sqrt{3}$, and $v = 7\,\mathsf{w}_3$ at level 1, with $\mathsf{w}_3 = (\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$: up to the factors $\omega^2-\omega$ and 7 the two smallest centre values are the separating generators of their weights, with every cut zero and the normal forms $(\omega^2-\omega)\,x_2$ and $7\,x_3$. □

56.4 The closing of a period in any number of shares

Exercise 56.5 (The law found by the closing of the class of three marks)**.** Let $\ell = P_{\binom{[3]}{1}}(\mathbf{1};1,1)$, the value of the centre ray of $\binom{[3]}{1}$ at the strength one (Exercise 56.1).

(i) Write the period as $P_0\sum_N \psi(N)$ by Theorem 45.21(i), and compute $\psi(N)$ for $N \leq 7$.

(ii) Find the recurrence of ψ, its symbol, and the singular points of the letter L_ψ.

(iii) Relate the singular points to the critical values of the cobasis letter on the strata of the simplex, and give the rate of the tail.

Solution. Receipts: `closing/peak_letter.py`, `closing/letter_exponents.py` and their logs.

(i) The family is $\binom{[3]}{1}$ with the masses $\mathbf{1}$ and the exponents $(1,1)$; its letters are $K = u_1+u_2+u_3$, of the degree 1, and $\Psi = u_1u_2+u_1u_3+u_2u_3$, of the degree 2. With the references of Theorem 15.13, $M_K = 1/1! = 1$ and $M_\Psi = 1/2! = \frac{1}{2}$, so $P_0 = \Gamma_{\binom{3}{1}}\left[\begin{smallmatrix}1,1,1\\3\end{smallmatrix}\right] M_K^{-1}M_\Psi^{-1} = \frac{1}{2}\cdot 2 = 1$. On the simplex $K = 1 = M_K$, so only the terms with $n_1 = 0$ survive, and with $(1)_N/N! = 1$,

$$\psi(N) = 2^N\,\mathbb{E}_{U\sim\mathrm{Dir}_{(1,1,1)}}\Big[\big(\tfrac{1}{2} - \Psi(U)\big)^N\Big] = \mathbb{E}\big[(1-2\Psi(U))^N\big],$$

the Dirichlet law at $(1,1,1)$ being uniform on the simplex, with $\mathbb{E}[U^{\boldsymbol\gamma}] = 2\,\gamma_1!\gamma_2!\gamma_3!/(|\boldsymbol\gamma|+2)!$. Expanding the powers of $1-2\Psi$ in monomials and taking these moments gives, exactly,

$$\psi(0),\dots,\psi(7) = 1,\ \tfrac{1}{2},\ \tfrac{4}{15},\ \tfrac{16}{105},\ \tfrac{7}{75},\ \tfrac{47}{770},\ \tfrac{4448}{105105},\ \tfrac{463}{15015}.$$

For instance $\psi(1) = 1 - 2\,\mathbb{E}[\Psi] = 1 - 6\cdot\frac{1}{12} = \frac{1}{2}$. So $\ell = \sum_{N\ge 0}\psi(N)$, a series of nonnegative rationals.

(ii) By Theorem 45.21(i), ψ satisfies a recurrence with polynomial coefficients. Method: the recurrences of the order 3 with coefficients of the degree 2 that hold for $N \le 30$ form a line, spanned by

$$\begin{aligned}(N+1)(N+2)\,\psi(N) - 2(N+2)(3N+7)\,\psi(N+1)\\ + (N+3)(11N+31)\,\psi(N+2) - 3(N+4)(2N+7)\,\psi(N+3) = 0;\end{aligned}$$

check: it holds exactly for every $N \le 35$; at $N=0$, $2\cdot 1 - 2\cdot 2\cdot 7\cdot\frac{1}{2} + 3\cdot 31\cdot\frac{4}{15} - 3\cdot 4\cdot 7\cdot\frac{16}{105} = 2 - 14 + \frac{124}{5} - \frac{64}{5} = 0$. The coefficients of N^2 are $1,-6,11,-6$, so the symbol is $1-6\lambda+11\lambda^2-6\lambda^3 = -(\lambda-1)(2\lambda-1)(3\lambda-1)$, and by Proposition 45.12(i) the letter L_ψ is singular at most at the reciprocals $z = 1,2,3$ of its roots; its radius of convergence is 1, the roots having the largest modulus 1, so it converges on $|z|<1$ as the theorem says, and its value at $z=1$ is ℓ.

(iii) By Theorem 45.21(i), $P_0L_\psi(z) = \int_\Delta \big((1-z)M_\Psi + z\Psi(u)\big)^{-1}d\omega(u)$ on the simplex. The three points $z = 1,2,3$ are the $z = M_\Psi/(M_\Psi - \Psi^*)$ for the critical values Ψ^* of Ψ on the strata of the simplex, 0 at the vertices, $\frac{1}{4}$ at the midpoints of the edges and $\frac{1}{3}$ at the centre: there the deformed letter $(1-z)M_\Psi + z\Psi$ acquires a critical point of the value 0 on a stratum. The walls of the family are $\kappa_S = 1$ for every nonempty proper S, and the counts of Ψ are $d^*(S) = |S| - 1$; so the rate of Theorem 15.13(ii) is $\varpi = \min_S \kappa_S/d^*(S) = 1$, attained at the three pairs, no two of which form a chain, so $k = 1$, and the tail is $\sum_{N'>N}\psi(N') = \Theta(1/N)$. □

Aliases

The text uses the program's own names. This list gives, for a reader who arrives from the literature, the classical names under which some of its objects and results appear there. An alias is a name and nothing more: the statement of the handbook, with its hypotheses, is the one that holds, and where the classical result is narrower or wider the handbook's statement decides.

Lists, tables and their letters

In this handbook	Classical name
a table, its marks and bases (Definition 7.1)	a matroid with weights on its bases, its ground set and bases
a list (the weights all 1)	a matroid
the list $\binom{\mathcal{E}}{r}$, $\lvert\mathcal{E}\rvert = n$	the uniform matroid $U_{r,n}$
the dual table	the dual matroid
a molecule; a connected table	a connected component; a connected matroid
the width $c(S)$ of a set (Definition 7.12)	the connectivity $r(S) + r(\mathcal{E} \setminus S) - r(\mathcal{E})$ of the set
the two-sum $\mathcal{A} \oplus_g \mathcal{A}'$ of two cells (Lemma 21.2)	the 2-sum of matroids
for the list of the spanning trees of a graph: the basis polynomial K and the cobasis polynomial Ψ	the spanning-tree polynomial, and the graph polynomial, also called the first Symanzik or the Kirchhoff polynomial
the Cremona (Theorem 8.14)	the Cremona transformation $\alpha \mapsto \alpha^{-1}$
the period at the full cobasis lean $(\mathbf{1}; 0, 2)$ of the list of the spanning trees of a primitive logarithmically divergent graph	its Feynman period $\int \Omega/\Psi^2$; the volume of the direction V_1 of that ray is its Hepp bound
the list $\binom{[n]}{1}$	the cycle matroid of the banana graph with n edges
the wheel W_p (Proposition 39.65); W_3	the cycle matroid of the wheel with p spokes; W_3 is the cycle matroid of K_4
H_4	the cycle matroid of a triangle with one edge doubled
N_6	$U_{3,6}$ with one basis removed: six points of a plane, exactly three of them collinear
V_8	the Vámos matroid
the whirl list on six marks (rank three, three dependent sets of three marks meeting pairwise)	the rank-three whirl

In this handbook	Classical name
F_7, A_9, Z_9 (Chapter 30)	the Fano plane, the affine plane $AG(2,3)$, the Pappus configuration

Values

In this handbook	Classical name
$(\mathsf{T}_{m;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$	$\zeta(m)$
$\Gamma(\frac{1}{2})^2$	π
$(\mathsf{T}_{2;(1)}[x]\,(\mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}}))((0,\infty))$; so $P_{\binom{[3]}{1}}(\mathbf{1};1,1) = 3\,(\mathsf{T}_{2;(1)}[x]\,(\mathbb{I}_{1+3\mathbb{Z}} - \mathbb{I}_{2+3\mathbb{Z}}))((0,\infty))$	$L(\chi_{-3},2)$; the value is $3L(\chi_{-3},2)$
$P_{\binom{[4]}{1}}(\mathbf{1};1,1) = 7\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$; the period of W_3 at $(\mathbf{1};0,2)$, $6\,(\mathsf{T}_{3;(1)}[x]\,\mathbb{I}_{\mathbb{Z}})((0,\infty))$	$7\zeta(3)$; $6\zeta(3)$
the signed sums of Trailmoments of lattice inputs at the cosets prime to $\lvert D\rvert$, weighted by the Kronecker signs	$L(\chi_D,2)$
the arc integrals of the three-mark centre (Part XI)	the log-sine integrals $\mathrm{Ls}_j(\frac{2\pi}{3})$; the second is the Clausen value $\mathrm{Cl}_2(\frac{2\pi}{3})$
the stacked Gammas at fifteenths, at twentieths	Chowla–Selberg periods of $\mathbb{Q}(\sqrt{-15})$, of $\mathbb{Q}(\sqrt{-5})$
the Gramma of one mark, $\mathsf{G}_{\nu;(1,-1)}(1,y) = 2y^{\nu/2}K_\nu(2\sqrt{y})$	the modified Bessel function K_ν
the centre values of $\binom{[n]}{1}$, $P_{\binom{[n]}{1}}(s\mathbf{1};s,s) = 2^{n+1-2s}\Gamma(s)^{-2}\int_0^\infty x^{2s-1}K_0(x)^n\,dx$	Bessel moments; at $n=3$ the equal-mass two-loop vacuum (sunrise) integral with propagator powers s in dimension $2s$

Rays

In this handbook	Classical name
the relations along a ray, reduced in a box (Definition 39.15)	integration-by-parts reduction on the parametric form, in the manner of Laporta
the strength	the parameter that plays the dimension
masters (Definition 39.1)	master integrals
the one-step matrix	the dimension-shift recurrence written as a first-order difference system
the law of [1]	the scalar recurrence obtained from a cyclic vector
a certificate (Theorem 39.21(ii))	a creative-telescoping certificate
the wall degree	the tropical degree of an insertion

In this handbook	Classical name
the search through boxes (Theorem 39.22)	Laporta's algorithm, its seeds grown until the targets reduce
the dimension of a ray (Definition 38.4)	the number of master integrals
the spectrum at infinite strength (Proposition 39.42)	the characteristic roots of a difference system (Birkhoff); a change of masters is a gauge transformation
the evaluation modulo primes in the reading procedure (Definition 41.8)	finite-field reconstruction
the closings (Definition 39.30)	the classical periods of the Laurent polynomial f^{-1}; the law read at the low end is the Picard–Fuchs operator of its pencil, read on coefficients
the closings of the centre ray of $\binom{[3]}{1}$	the sums of squares of trinomial coefficients
positive selection (Theorem 41.3)	Apéry limits; the minimal solution of Pincherle and Perron
positivity as the moment problem of the stride's law (Proposition 41.4); its rate (Theorem 41.5); what it cannot see (Proposition 41.6)	the Hausdorff moment problem, its four families of Markov and Lukács; the Green's function of the complement of a segment; the indeterminacy of a moment problem along a Stieltjes transform
the stride's law (Definition 40.1)	the pushforward of Lebesgue measure under the stride, a density of states; the values are its moments
the gauge end (Theorem 40.6)	Laplace's method with the Morse lemma at the end point, and the Frobenius method at a regular singular point; the germ is the Borel sum of the expansion at large strength
the torus value (Definition 40.11)	the zeta Mahler measure of the letter; at three marks the moments of the planar walk of three unit steps
the merit (Definition 43.4, Theorem 43.5)	Apéry's criterion
the law of the values of $\binom{\mathcal{E}}{1}$ (Theorem 42.12)	the recurrences of the Bessel moments $\int_0^\infty x^{2s-1}K_0(x)^n\,dx$

The motive and the content

In this handbook	Classical name
the motive and the motivic period of a family (Definitions 34.1 and 34.5)	motivic periods in Brown's affine model
small steps along the tree (Theorem 34.13)	Brown's small graphs principle in its affine form, here for families of lists
dual pairs and full leans (Corollary 34.18)	at $(0, 2)$, the product identity of Feynman periods at a two-vertex cut (Schnetz), as an identity of motivic periods

In this handbook	Classical name
chains (Definition 45.4); the content (Definition 45.1)	iterated integrals on $\{0\}$ and the roots of unity of order M; the multiple polylogarithms at roots of unity
the cutting rule (Definition 45.8, Theorem 45.9)	Goncharov's coaction on iterated integrals
critical primes (Definition 43.11)	primes of bad reduction
separation by conjugates (Theorem 34.21)	motivic periods as functions on the torsor of periods; the injectivity of the period alone is Grothendieck's period conjecture
the motivic chains (Proposition 45.10)	the motivic iterated integrals of Goncharov and Brown; the motivic multiple polylogarithms at roots of unity
the motivic content $\mathcal{P}^{(M)}$, $M = 1, 2, 3, 4$ (Definition 45.14)	the motivic multiple zeta values, the motivic Euler sums, the motivic multiple polylogarithms at the third and fourth roots of unity
the cuts D_r	Brown's infinitesimal coaction D_r
the separating generators w_N	$\zeta^{\mathfrak{m}}(N)$ for N odd, $\log 2$, $\log 3$, and for N even $\mathrm{Li}^{\mathfrak{m}}_N(\zeta_M) - \mathrm{Li}^{\mathfrak{m}}_N(\zeta_M^{-1})$, of the values $i\sqrt{3}\,L(\chi_{-3}, N)$ and $2i\,L(\chi_{-4}, N)$
the normal form (Theorem 45.15(iii))	Brown's decomposition into the f-alphabet
the polynomial generators of Lyndon words	Radford's theorem on shuffle algebras
the stuffle product, the shuffle product of chains, the relation of index one	the double shuffle relations; Hoffman's relation
the trails $T(\mathbf{k})$ with every $k_i \in \{2, 3\}$ (Exercise 56.3)	the Hoffman elements
the second generator of weight twelve, of depth four (Exercise 56.3)	the relation $28\zeta(3,9) + 150\zeta(5,7) + 168\zeta(7,5) = \frac{5197}{691}\zeta(12)$ of the cusp form of weight twelve (Gangl, Kaneko and Zagier), and the depth of Broadhurst and Kreimer
the values of the content and its generators (Corollary 45.16)	Grothendieck's period conjecture for the mixed Tate motives over $\mathbb{Z}[\mu_M, \frac{1}{M}]$, stated on generators
a separating generator and its measure (Lemma 44.17); separators at once (Corollary 44.13)	irrationality and linear independence measures; the criteria of Siegel and Nesterenko
the model of a ray and its relations as exact forms (Definition 39.7, Proposition 39.8)	the twisted de Rham cohomology of the parametric representation and its integration-by-parts identities; a ray is one motive with a family of de Rham classes, as in the theory of Feynman integrals in dimensional or analytic regularization
the pencil module $\mathcal{G}_F$, its fibre integrals, singular values and vanishing ranks (Definition 39.47)	the Gauss–Manin system $H^0\varphi_+\mathcal{O}$ of the function $\varphi = f^{-1}$; Gelfand–Leray residue forms; the critical values and the dimensions of the vanishing cycles

In this handbook	Classical name
the moment side of the pencil (Proposition 39.48)	the algebraic Mellin transform of a holonomic module in one variable
asymptotic native gauges and values (Definition 38.29)	Rabier's generalized critical values; critical points at infinity
the insertion lattice, the native algebra, a tame high end (Definition 39.43)	the Brieskorn lattice, the Jacobian algebra, a cohomologically tame function (Sabbah)
the far end of the pencil (Proposition 39.54)	a point of maximal unipotent monodromy; the torus fibre integral is the classical period $\sum_j \mathrm{CT}(\varphi^j) t^{-j-1}$ of the Laurent polynomial φ
a hinge tree; the canonical hinge tree (Definition 23.15, Theorem 23.16)	the decomposition of a connected matroid into 3-connected pieces glued by 2-sums (Cunningham–Edmonds); for a graph, its SPQR tree
the homogeneous reading of a node (Definition 39.55)	the 2-sum formula $K_{M_1 \oplus_2 M_2} = K_{M_1 \setminus e} K_{M_2 / e} + K_{M_1 / e} K_{M_2 \setminus e}$ for basis polynomials, iterated along the tree
the pencil along a hinge tree (Theorem 39.56)	the Gauss–Manin system of a composite map as the composite of the direct images, by the functoriality of direct images and the Künneth formula
the parallel and series rules (Corollary 42.21)	the rules for conductances in parallel and in series
the corners of a wall of width one (Proposition 38.26)	points at infinity at which the closure of a level set of the Laurent polynomial is tangent to the toric boundary
rational data on a Kummer cover (Proposition 34.20)	multivalued forms of hypergeometric type as sections of local systems of rank one; cyclic coverings
the class density ν_s (Definition 42.19)	the density of the squared distance after s unit steps of a planar random walk with independent uniform directions
the closings of $\binom{[s]}{1}$ and the solutions V_s of the class (Theorem 42.28)	the even moments of planar random walks; the Bessel moments and the symmetric power of the Bessel equation; for $s = 3$ the sunrise, an elliptic family
a list read against its cells; the bubble of two classes (Theorem 42.20, Corollary 42.25)	the dispersive (Källén–Lehmann) representation of a self-energy inserted in a propagator; the Källén function; $\sum_k z^k / k!^2 = I_0(2\sqrt{z})$
the norm of a cell; a mark of norm m; the two-sided core (Definition 42.19)	the squared mass of a propagator; a massive line; the graph polynomial with masses
the hinge module of a class (Proposition 42.29)	a direct image of $\mathcal{D}$-modules computed by its Fourier transform, an exponentially twisted Gauss–Manin system; the irreducibility of the symmetric powers of the Bessel module (Kolchin)

In this handbook	Classical name
the source count (Theorem 42.32, Proposition 42.33)	Kashiwara's index formula for direct images; Landau singularities and their multiplicities
closed form; named function; alphabet; the serif alphabet (Definition 18.19)	a closed-form expression, in the sense in which Γ, the Beta function, the Gauss hypergeometric function ${}_2F_1$ and the polylogarithms Li_n are closed forms
the series of stacked Gammas read from words (Proposition 18.20(iv))	the Barnes integral of $B(k,k)\,{}_2F_1(k,k;2k;1-\mathsf{m})$ and its Gauss series; the Mellin–Barnes integral of $\mathrm{Li}_n(z)$
the value of a table with norms on its marks, and down the hinge tree, as a closed serif word (Proposition 42.26)	the Mellin–Barnes representation of a Feynman integral with massive propagators, the masses entering as powers of the Mellin variables; a banana subgraph entering through its Bessel moment
the periods of a class are not unipotent (Corollary 42.30)	they are not multiple polylogarithms with algebraic arguments and coefficients: that alphabet is not closed on the class
a chain over an equation; every solution is read through chains over its equation (Definition 45.19, Proposition 45.20)	an iterated integral whose kernels are built from the solutions of the irreducible factors of a Picard–Fuchs equation: multiple polylogarithms when every factor is trivial, the iterated integrals with kernels from the periods of elliptic curves (elliptic multiple polylogarithms, iterated integrals of modular forms) and of Calabi–Yau operators beyond; variation of constants along a composition series
the values of a ray read through chains over its tree (Corollary 45.22)	the master integrals of a Feynman integral as iterated integrals over the irreducible blocks of its differential equation, the blocks read off its subgraphs
every period at rational data as a moment of one integral ray (Corollary 45.22(iv))	the Mellin transform, at a rational point, of the density of the image of the invariant measure of the positive orthant under a Laurent polynomial
the letter of the closing along the tree; the load sum of a vertex (Corollary 45.23)	the Picard–Fuchs equation of a one-parameter deformation of the integrand, computed as an iterated direct image along the decomposition into 3-connected pieces, with the deformation applied at the root
the group of a module, of a function and of an input; its unipotent and reductive parts (Definition 45.24, Proposition 45.25)	the differential Galois group and its Lie algebra; Picard–Vessiot theory, the transcendence degree of the Picard–Vessiot extension; Schlesinger's theorem for regular singular equations
powers add nothing, distinct factors add (Proposition 45.26)	the Galois group of a tensor construction as a quotient; Goursat's lemma (the Goursat–Kolchin–Ribet lemma) for a sum of irreducible differential modules

In this handbook	Classical name
a full Jordan block; a power; the far end of the pencil (Theorem 45.27, Corollary 45.30)	maximal unipotent monodromy; Gabber's theorem on irreducible groups containing a regular unipotent element; the principal SL_2; operators that are symmetric powers of operators of order two
the class read by the tree and by its stride's law (Theorem 45.28)	$\mathsf{G}_{0;(1,-1)}(1,y) = 2K_0(2\sqrt{y})$, the modified Bessel function, and $\sum_k y^k/k!^2 = I_0(2\sqrt{y})$; the differential Galois group SL_2 of the modified Bessel equation of order zero (Kolchin); the Bessel moments $\int_0^\infty y^{k-1}\big(2K_0(2\sqrt{y})\big)^s\,dy$ of the equal-mass banana integrals; the symmetric powers of the modified Bessel equation of order zero; the monodromy of the banana Picard–Fuchs operators, of Calabi–Yau type
the word along the canonical tree (Corollary 45.29)	a period read over the Cunningham–Edmonds decomposition: Gamma factors at the series and parallel pieces, the periods of the 3-connected pieces at a full lean, Bessel moments for bundles of parallel edges
the group is computable (Proposition 45.31)	Hrushovski's algorithm for the differential Galois group of a linear differential equation over $\overline{\mathbb{Q}}(t)$
the inputs and the group of a word (Definition 45.32)	the differential Galois group of the special functions that a representation of an integral integrates against
the transforms satisfy linear equations (Lemma 45.33)	holonomic functions are stable under integration and under the Mellin transform; the Picard–Fuchs equation of a period in a parameter of its integrand
the word along the canonical tree paid in work or on scales (Theorem 45.34)	Mellin–Barnes representations, of dimension growing with the number of lines, against position-space representations of a Feynman integral as integrals over few points of products of propagators, Bessel functions for massive lines; a bundle of parallel lines as a power of one propagator
the closing in any number of shares (Theorem 45.21)	multiple Mellin–Barnes integrals closed residue by residue; the Frobenius method at a regular singular point; the period as a series of a D-finite sequence
the triangles of classes $\Delta(s_0, s_1, s_2)$ (Section 55.4)	the cycle matroids of a triangle with its three edges replaced by bundles of s_0, s_1, s_2 parallel edges

In this handbook	Classical name
the module of a family; its shifts, masters and shift matrices (Definition 47.3, Theorem 47.4)	the twisted de Rham cohomology of the complement of the letters; the master integrals of the integration-by-parts reduction of a family of Feynman integrals; the contiguity (raising and lowering) relations of a GKZ system
boxes in all the data; the search stops (Theorem 47.8)	Laporta's algorithm: integration-by-parts identities generated on seeds ordered by weight and solved by Gaussian elimination over the rational functions of the parameters
closings in all the data; the elements of value zero (Definition 47.9, Theorem 47.11)	constant terms of Laurent polynomials, the integrals over the compact torus at nonpositive integer exponents; the kernel of the pairing of twisted cohomology with one integration cycle
masters from a box (Proposition 47.13)	a basis of the twisted cohomology, with its difference equations in all the parameters, from finitely many integration-by-parts identities, the relations they miss generated by the commutation of the difference operators and the identities at one point
the number of masters (Proposition 47.16)	the number of master integrals as the Euler characteristic of the complement of the polynomials; the vanishing of twisted cohomology below the middle degree at generic exponents; the maximum likelihood degree of a very affine variety, the number of critical points of a generic master function
the values separate the module (Proposition 47.15)	the injectivity of the Mellin transform in the exponents of the monomial: a linear relation among parametric integrals, with coefficients rational in all the parameters, that holds identically is a consequence of the integration-by-parts identities; a twisted cohomology class whose period over the positive cycle vanishes identically in the exponents of the monomial is zero
value zero on a subspace of the data; native directions and the expansion at a native gauge (Proposition 47.14)	deciding a linear relation among parametric integrals on a linear subspace of the parameters by Laplace's method along one direction, at the critical point of the phase, the coefficients of the asymptotic expansion being rational in the remaining parameters and limited in number by the difference equation along that direction
a family of positive letters on its space of directions, and its module (Definition 48.1, Theorem 48.3)	the twisted de Rham cohomology of the complement of a family of Laurent polynomials on a torus; the Mellin side of an A-hypergeometric (GKZ) system with all its exponents as parameters

In this handbook	Classical name
a share reading; the integrand module (Definition 48.4, Theorem 48.5)	a Mellin–Barnes representation, an integral over Gamma functions of linear forms times smaller integrals, with the integration-by-parts reduction done on the smaller integrals
the path of a basis through a chain of bunches (Definition 48.6, Theorem 48.7)	the Mellin–Barnes splitting of a product of transfer matrices, whose shares are the flows of a Markov chain on the states
exponential periods, their domains and their modules (Lemma 48.8)	Laplace-type integrals of products of powers of polynomials, whose convergence is read on the tropicalization of the polynomials and whose derivatives close by the finiteness of the de Rham cohomology of a holonomic connection with an exponential factor
the group at several scales; the inputs and the group of a word (Definition 48.9)	the differential Galois group of an integrable connection in several variables (Picard–Vessiot theory for commuting derivations, Kolchin's), the Tannakian group of the connections it generates
a tree of nested bunches read on its shares (Definition 48.11, Theorem 48.12)	the Mellin–Barnes splitting of a nested multilinear product (a tree tensor network), its shares the flows along the tree conserved at every vertex
the blocks of a node read on its scales (Definition 48.13, Theorem 48.14)	the Schwinger or Laplace parametrization of a power of a sum, under which terms in disjoint variables exponentiate to a product of transforms; series and parallel composition read through Laplace transforms
the direct image of a reading; the module of a family from its nodes (Definition 48.17, Theorem 48.18)	the direct image of a holonomic module along the projection of a Mellin–Barnes representation, read on the Mellin side as the quotient by the shifts along the fibres; the master integrals of a family found from those of its subintegrals
closings through the tree (Theorem 48.18(v))	the constant term of a product of Laurent polynomials in disjoint sets of variables, a product of constant terms, summed over the multinomial splits of the powers along a tree tensor network
the twisted direct image of a block; the module of a transform from its block (Definition 48.19, Theorem 48.20)	the Mellin side of an exponential (confluent) integral: its differential equations in the coefficients found from the difference equations of its Mellin transform, a derivative in a coefficient acting as multiplication by a Mellin variable; for a Gramma, a confluent A-hypergeometric system, its Euler operators the pins and its box operators the independence of the lifts

In this handbook	Classical name
value zero by finitely many closings (Proposition 47.12)	deciding a linear relation among parametric integrals, as identities in all the parameters, by finitely many exact evaluations of residues along finitely many parallel lines of the parameter lattice
the closings for every family of letters of tables; the working interest of several active molecules; a factorization of the weights (Theorems 48.23 and 48.24, Proposition 48.21)	the integral of a multihomogeneous form over a product of projective spaces, and a Mellin–Barnes splitting of a nonnegative tensor of coefficients into products, one variable for each term of a nonnegative factorization
the procedure in all the data (Definition 48.25, Theorem 48.26)	a complete symbolic algorithm for a class of parametric integrals: classification, reduction to master integrals with difference and differential equations in all the parameters, certificates for every relation, and the decision of linear relations among the values

The family as inference

In this handbook	Classical name
the interaction of a split of the prior marks of a regression design (Proposition 49.27)	minus the logarithm of the generalized variance inflation factor
